After the CHAIRMAN had proposed the toast of "The Queen," Mr. J. F. ROLLESTON, J.P., proposed "The Corporation." He spoke, as a past member of the Corporation, of the business capacity of the Council as shown by their flood, drainage, gas, and chemical works. In spite of the liberal improvements which had been carried out, the rates were on a down grade. He congratulated the Gas Committee upon making friends with the rival illuminant, the electric light, and taking it into partnership.

The MAYOR responded, enumerating the good work done by the different committees.

Mr. J. S. RAWORTH proposed "The Gas Committee and Success to the Electric Lighting Undertaking" in a humorous speech, in which he referred to the nuptials of the two rivals, much amusement being caused by the band striking up "The Wedding March." He alluded to the business capacity of the committee and the great engineering skill of Mr. Colson, who was the active designer of the whole station.

Alderman LENNARD responded on behalf of the committee and himself. He remarked that they had spent only £33,000 out of £42,000 which were borrowed. They were thus in the position of being the only town which had not exceeded the original estimated cost. Lamps to the extent of 3,000 16 c.p. were now fixed, and he was confident that they would pay their expenses this year.

Sir THOMAS WRIGHT proposed the toast of "Trade and Commerce," to which Sir COURTENAY BOYLE, K.C.B., responded in an able speech.

Alderman E. WOOD proposed the last toast, that of "The Contractors," to which Mr. HUDSON replied on behalf of Messrs. Hicks, Hargreaves, and Co., and Mr. COLSON on behalf of the Corporation officials.

CITY AND GUILDS OF LONDON INSTITUTE.

SOLUTIONS TO THE NUMERICAL QUESTIONS IN ELECTRIC LIGHTING AND POWER TRANSMISSION.

ORDINARY EXAMINATION, 1894.

2. A straight wire carrying a continuous current of 500 amperes lies at right angles to the magnetic flux in a field the intensity of which is 10,000 lines per square centimetre. State the force in pounds per foot of the wire tending to produce lateral displacement.

Solution 2.—The mechanical force experienced by a conductor carrying a current in a direction at right angles to

Digitized by Google

the lines of force of the magnetic field in which it is placed is proportional to the strength of the current, to the intensity of the magnetic field, and to the length of the conductor; or, algebraically,

$$F \text{ (dynes)} = H \times C \times l,$$

where H = number of lines per square centimetre;
C = current strength in absolute units;
l = length in centimetres.

If C be given in amperes, then

$$F \text{ (dynes)} = H \times C \times l/10.$$

In the example l is 1ft., and this equals 12 × 2·54cm., since 1in. = 2·54cm. Therefore substituting the values given, we get

F = 10,000 × 500 × 12 × 2·54/10 dynes per foot length;
= 15,240,000 dynes;
$= \frac{15,240,000}{981}$ grammes weight. Since one gramme weight = 981 dynes,
$= \frac{15,240,000}{981 \times 453·6}$ pounds weight. Since one pound = 453·6 grammes,
= 34·25 pounds weight.

Answer.—34·25 pounds.

Note.—The above solution is by the method of "first principles," and is useful as an example of changing from absolute units to other systems of units. The general formula is—

$$F = k \,.\, H \times C \times l,$$

where k is a constant depending on the system of units used. In the above example F is required in pounds, and l is given as 12in., in which case $k = 57 \times 10^{-8}$; whilst C is in amperes, and H in C.G.S. units. Substituting these values—

$$F \text{ (pounds)} = 57 \times 10^{-8} \times 10,000 \times 500 \times 12 = 34·2 \text{ pounds.}$$

6. Current is required along a street 2,000ft. long at the rate of one ampere per 10ft. of frontage. Give sectional area of conductor so that the difference of pressure between any two lamps shall not exceed two volts in the following two cases:

(a) The current being supplied at one end;

(b) The current being supplied midway.

[N.B.—The resistance of a copper bar 1,000ft. long and one square inch in cross-section may be taken at ·008 ohm.]

Solution 6.—(*a*) Assuming a lamp to be placed between the mains at intervals of 10ft., there will be 2,000/10 or 200 lamps; and if each requires one ampere, then 200 amperes will be required. Let R be the resistance between two lamps, then 200 × R = 2, or R = 1/100 ohm = resistance of 10ft. Now, the resistance of a copper bar 10ft. long and one square inch in cross-section is $\frac{1}{100}$ of ·008 ohm, or ·00008 ohm. Therefore, if A is the required area of cross-section, then

1/100 ohm : ·00008 ohm :: one square inch : A square inch.

$$\therefore A = \frac{·00008}{1/100} = ·008 \text{ square inch.}$$

(*b*) When the current is supplied midway the mains will be required to convey only 100 amperes, so that

100 × R = 2, or R = 1/50 ohm = resistance of 10ft.

As in (*a*),

1/50 ohm : ·00008 ohm :: one square inch : A square inch;

$$\therefore A = \frac{·00008}{1/50} = ·004 \text{ square inch.}$$

7. Explain numerically the relations between the dyne, the erg, the joule, the kilogramme, the British horse-power, and the metric (French) horse-power.

Solution 7.—The *dyne* is the C.G.S. unit of force, and is such that it produces an acceleration of one centimetre per second when acting on a mass of one gramme for one second. The *erg* is the C.G.S. unit of work, and is the work done in overcoming a force of one dyne through a distance of one centimetre. Thus the erg is one dyne-centimetre. The *joule* is the practical unit of work, and is 10,000,000 or 10^7 times as great as the erg. Thus one joule = 10^7 ergs. The *kilogramme* is 1,000 grammes, and the gramme is the C.G.S. unit of mass, and is the mass of a cubic centimetre of distilled water at 4deg. C. Now, gravity imparts to a mass of one gramme an acceleration of 981 centimetres per second, and the force with which the earth attracts any mass is termed the *weight* of that mass, so that the weight of one gramme is equivalent to a force of 981 dynes. Consequently, the weight of one kilogramme equals 981,000 dynes. *The British horse-power* is the practical (British) unit of power, and power is the rate of doing work. The absolute unit of power is one erg per second, whilst 10,000,000 ergs per second is the practical unit of power in the C.G.S. system, and is termed the *watt*. One horse-power is 746 watts (approximately), or 7,459,571,687 ergs per second. *The metric* (*French*) *horse-power* is 735·75 watts, or 7,357,500,000 ergs.

9. A Gramme armature, intended for a two-pole field, has 120 turns of conductor wound upon it. Give the total flux required through armature core if an E.M.F. of 100 volts is to be induced at a speed of 1,000 revolutions per minute.

Solution 9.—The E.M.F. induced in an armature rotating in a two-pole field is given by the following formula:

$$E = M_F \times T_{aw} \times n / 10^8,$$

where E is given in volts;
M_F is the magnetic flux;
T_{aw} is the number of turns on the armature;
n is the revolutions per second.

Substituting the given values:

$$100 = M_F \times 120 \times \frac{1,000}{60} \times \frac{1}{10^8};$$

$$\therefore M_F = \frac{100 \times 60 \times 10^8}{120 \times 1,000} = 5,000,000 \text{ lines.}$$

Answer.—5,000,000.

10. Calculate the number of ampere-turns of excitation required to magnetise, up to 14,000 lines per square centimetre, a soft iron ring, 20in. in mean diameter, made of round iron 1in. thick. (Assume permeability = 800).

Solution 10.—The lines of induction induced in an iron ring on which is wound wire through which a current is passed is given by the following formula:

$$B = \frac{·4 \pi C n \mu}{l} \text{ C.G.S. units,}$$

where B is the flux per square centimetre;
μ is the permeability;
l is the length of the helix of wire;
C n is the number of ampere-turns.

Since 1in. = 2·54cm., $l = 20 \times 2·54 \times \pi$ centimetres. Then by substituting the given values we get—

$$B = \frac{·4 \pi \,.\, C n \,.\, 800}{20 \times 2·54 \times \pi} = 14,000,$$

$$\therefore C n = \frac{14,000 \times 20 \times 2·54}{·4 \times 800} = 2,222·5.$$

Answer.—2,222·5.

ALTERNATING AND INTERRUPTED ELECTRIC CURRENTS.*

BY PROF. GEORGE FORBES, M.A., F.R.S., M.I.C.E.

When I was asked by Sir Frederick Bramwell to give a short course of lectures here, I asked him what subject he would like

* Lecture delivered before the Royal Institution.

Digitized by Google

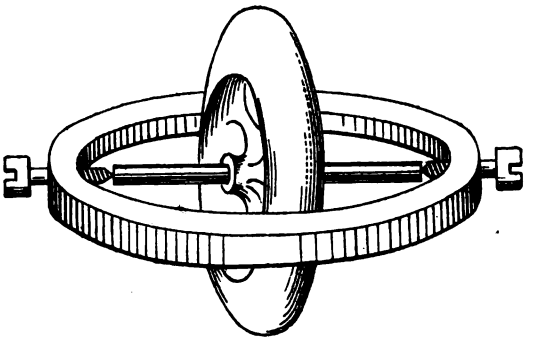
me to lecture on, and he said, "Some physical subject." I am aware that at the Royal Institution it is generally the custom to deal with principles rather than applications of science, consequently I thought over what might be the best subject to discourse on. It happened that in the course of the work upon which I have been engaged during the last few years I have had occasion to try and find some simple means of expression to convey to my own mind, and also to the minds of others, certain somewhat obscure electrical phenomena which take place especially when using alternating or interrupted currents, and I arrived at a method of producing mechanical analogies to the various cases of the propagation of electricity which was of such very great assistance to myself, and which enabled me so much easier to convey some intelligent idea of these curious electrical actions to others, that I thought it might be well to incorporate them in the present lecture.

Prof. Dewar told me yesterday that you would be expecting me to talk about the Niagara Falls, and that you would be disappointed if I did not. I can only say that I cannot imagine why any such opinions should have been held, and I can only express regret if I am disappointing those present by taking up a different subject. However, I have this to say, that while the present lecture does deal with some of the work which has been going on there, it deals far more directly with submarine telegraphy. The next two will deal almost entirely with problems which have been cropping up in the work of utilising those great falls and distributing the power in the neighbourhood, so that I trust it will not be altogether a disappointment to those who had expected a different course.

Before beginning my subject I have also to say that I have a good many experiments to show you to-day, and in the following lectures, which I do not wish you to think for one moment are original—some are somewhat striking, but they have been evolved after very patient work by others than myself. I particularly mention the name of Mr. Campbell Swinton, who has placed at my disposal some extremely beautiful apparatus which I shall have frequent occasion to refer to. Others have assisted me much. Dr. Muirhead has been invaluable to me in the assistance he has given me in illustrating the present lecture by enabling me to produce before you some of the phenomena which are produced in submarine cables. This is a subject which has hitherto been wrapped up in a certain amount of obscurity—of mathematical symbols; and while dealing with that it is my hope that I may be able to divest the treatment of the subject of those difficulties, and make the phenomena which appear in submarine cables generally intelligible to anyone.

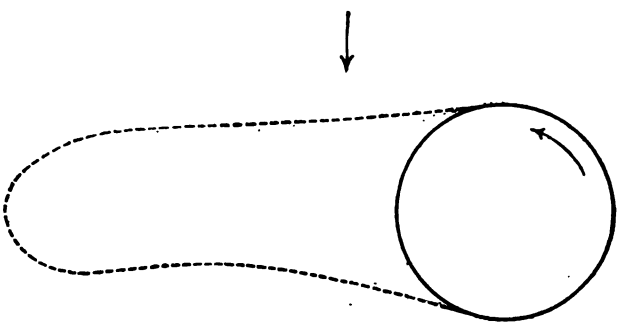
When we speak about the propagation of electric currents through an Atlantic cable, we know that while the electricity is passing into the cable a charge of electricity is being imparted to the outside of it, the cable is being charged, and that prevents the rapid propagation of the current through it. Now, it is all very well to talk about it in that sort of language, but it is not very intelligible, and for this reason, that it is difficult to understand. We do not understand exactly what we mean by electricity. All the time we are using such a phrase, we are trying to grasp some mechanical analogy which shall make it intelligible to us. For instance, in dealing with the propagation of electricity, it has been very common in the past to treat of electricity by the analogy of a flow of water through pipes, and an excellent analogy it is. The pressure of the water is the E.M.F., which compels the water to move, the velocity of the water acquired in the pipe is the current, and the friction of the pipe represents the resistance of the wire. If you have a pipe in a complete circle, with a centrifugal pump at one part and the whole of the power being used in the friction of the pipe, you have there the analogue of a battery with a certain pressure, of a closed circuit carrying a current, with a certain amount of resistance; and the velocity of the water increases and increases until the backward force caused by the friction of the pipe is equal to the motive force, or the pressure of the water, in the centrifugal pump. That is the ordinary analogy employed for the most ordinary phenomena. We might extend that analogy, and instead of using up the whole of the energy of the centrifugal pump in the friction of the pipe, which is equivalent to heating the conductor, we might place a very narrow bit of pipe at one end of it. The energy would then be almost entirely consumed in that narrow pipe at the far end. Now, that is analogous to the light in this room. The centrifugal pump is the dynamo in the central station, the wires that go round are the wires that go to and from the central station, the narrow bit of pipe at the far end where the power is used up is the analogue of the incandescent lamp. Instead of placing that small pipe at the end, we might have a little water motor, like a turbine, and we should then have a central pump, a limited amount of whose power is used up in friction in the pipe, and at the end the motor, which might be doing useful work. There we have the power in a central station, in which the centrifugal pump represents the dynamo, the pipe represents the wires along which a current is flowing with a certain amount of resistance, and the turbine at the far end represents the electric motor which is driving the machinery. That is a very useful and simple sort of analogy, but when we come to some more obscure points this analogy fails to be quite so easily understood, though in many cases it is a very good one indeed. I am speaking about the difference between ordinary cases which are easily understood, and cases which are somewhat more obscure. In the ordinary ways of electric lighting in a house or from a central station the method of the propagation of electricity is comparatively simple, and any person who has played with a battery and wires is able to see at a glance what will happen when you connect the wires to the dynamo and then to the lamp. But there are other phenomena which come in later, especially when using alternating currents, which are not so easily understood. As I am going to adopt mechanical analogies to show the electrical phenomena, I may well here adopt a mechanical analogy to show you the different class of phenomena which I wish to illustrate. There are many mechanical phenomena which are perfectly obvious to any intelligent person when looking at them. If you have a steelyard with a heavy weight supported at the short arm and a light weight at the long arm, it is perfectly natural that the heavy weight may be supported by the light weight without going into the mathematics of it or measuring the quantities and proportions—the result is a very obvious one to every person. When I exert pressure upon a screw press, I with a very little pressure and a large motion of my hand produce a very small downward motion, but a huge pressure upon a copying book, for instance: that is a transformation of mechanical energy which is perfectly obvious. And so with the different mechanical powers—the lever, the wheel, and axle working a crane—any of these are perfectly obvious.

I will now show you one or two not quite so obvious phenomena, and the first which will occur to everyone of you here is simply the gyrostat, which everyone of you know, but



which I wish to show you because it illustrates what I am working at. [*Experiment.*] All I wish to say with respect to the gyrostat is that it takes a little time and a little thought to realise why it is that the wheel does not twist in the direction in which the obvious forces are impelling it. That is a thing which requires a considerable amount of thought before you arrive at a correct conclusion. Why does it twist round, and in which direction does it twist? These are things which are not perfectly obvious, and which do require a very considerable amount of thought to make them clear. If I were able to show you a mechanical analogy which would make that clear, it would be a great step. And in the case of the electrical phenomena I think I shall be able to show you some analogies which are equally good.

Here I have a chain caused to revolve by means of an electric motor, and the motions which take place are those which are not perfectly obvious to the very well-trained mechanic.



[*Experiment.*] When I draw this chain towards me it acts somewhat like a rigid bar. If I impress a motion on it it retains that motion; and if I draw the chain out for a considerable distance and let it go, it goes through a series of motions which are somewhat difficult to understand, which you would not have foreseen if you had been asked to say what was the action.

MUNICIPAL ELECTRICAL ENGINEERS.

What to do with mothers' sons is becoming a more and more important problem every day in the households of the United Kingdom. A profession that has few prizes and many blanks, especially when the prizes themselves have no very great attraction, does not attract the best men. It may be that it contains openings for hundreds, if not thousands, of units, but few of these units come into prominence because of talent. The electrical engineering profession is such an one. It employs many men, most of whom are mere items, and will remain items to the end. These items are intensely ignorant of the why and wherefore of their everyday work. Their only view is bounded by the wall of as much pay as possible and as little work as possible. Their ignorance compels them to wait for assistance at the rise of every little difficulty. We should prefer to see more men ready to grapple with the difficulty and capable of stepping into a higher position when the chance offers. When the standard of knowledge in any profession is of a high order, wages and salaries also average higher in amount, because the universal law of supply and demand acts in this direction. The most recent development in the electrical industry seems to warrant the conclusion that in future the number of prizes will be greater, and this will lead to greater competition for such prizes, and inevitably to a higher standard of knowledge in certain ranks of the profession. Hitherto, putting aside the question of consulting engineers, with which we are not now dealing, the best positions open to general competition have been those of municipal electrical engineers. The remuneration, except in a few cases, has, however, been too low, but this may probably have arisen from the youth of the profession. No one in the earliest days could adequately grasp the value of the work to be done, and municipalities were cautious in offering too much. As time went on, it became clear that to successfully manage a central station demanded capacities of a much higher order than were originally thought necessary. In more than one case success has been taken as obtained automatically, but the illness or departure of the successful organiser has opened the eyes of those who controlled the management. It is an open secret that some companies have found the loss of a man of far greater importance than they ever suspected. We, however, have no intention of dilating further upon the settled conviction of business men, that the proper course to pursue is to employ those who know their business, and to pay them well for their work. Experience is only gained by age, and experience is worth paying for. To return to the object of this article—a reference to the step taken by the St. Pancras Vestry. From the advertisement it will be gathered that this Vestry look upon their electrical engineer somewhat in the same light as they do their ordinary engineer, and are desirous of placing the two in a measure upon a similar footing. Perhaps, however, a better analogue would be that of a gas engineer to a local authority. The gas engineer is expected to organise, manage, design, and carry out

Digitized by Google

the ordinary work of extensions. Now, whatever the attainments necessary to successfully manage a central electric light station, other special attainments are required if the manager is to act as engineer also—to design, specify, and superintend new work. That we can obtain men having the requisite attainments for both classes of work is undoubted. Is the salary offered sufficient to induce the men of higher calibre to enter the profession? Considering that few such positions are yet open to competition, we think that the St. Pancras authorities are making a fair offer, and a commencing salary of six hundred pounds a year will probably lead to an able man rising to one thousand pounds a year. The latter figure will not be found in any accounts for some years to come, but it is evidently within the bounds of practical electric lighting politics. If central-station work increases and is successful, as it seems likely to be in the hands of the authorities, we shall certainly see in not a few instances an expenditure of a million pounds or so for the complete lighting of a large city. The electrical engineer will then have a most responsible position in the earning sufficient revenue to pay interest and repay loan account, and ought to be adequately remunerated. The amount one thousand pounds is none too large for this responsibility, but is good enough to obtain the best men. We trust that those already in the profession will give due attention to these facts, and endeavour to gain the experience necessary to satisfactorily fill these positions.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

NOVEL APPLICATIONS OF ELECTRICITY.

SIR,—The other day a friend of mine who is a jeweller asked me jokingly whether I could rig up an electric shock-producing device for testing diamonds and the detection of sham or paste diamonds. After thinking the matter over, I presented him, a couple of weeks later, with the following apparatus to his entire satisfaction: To the spindle of a small electric motor is attached a small thin disc made of aluminium and placed in horizontal position. A clamp with a small flat spring, and provided with an adjustable screw, holds fast a ring or any other article with the real or sham "brilliant." The ring, etc., is moistened, and slowly moved by hand towards the disc, driven at a high speed by the motor, thus applying, so to speak, a brake to the motion of the disc. The idea is based on the fact that if a sharp piece of aluminium be rubbed on moistened glass, brilliant metallic markings result on the glass diamonds, but not on those which are genuine. If some metallic marks are found on the so-called "diamond," then, of course, it is not a genuine article; otherwise it is a real diamond of the first water.

I am not a philatelist, but by some chance I became a possessor of a few hundreds of good genuine stamps. As I am of original mind, I did not gum them into the usual old-fashioned stamp album, but I rigged up a special apparatus for the purpose: An endless thin leather band is driven by means of an electric motor at a very low speed. The stamps were pasted to the band, and this combination was fixed inside a longitudinal box, ornamented externally with velvet and fancy brass nails and rosettes. At a certain part of the box is fixed a small movable brass tube provided with an objective glass. A small electric incandescent lamp, provided with a silvered reflector, is also fixed inside the box. By pressing on the pear-shaped button every stamp is seen magnified many times its size, is succeeded soon by another stamp, and at the same time more "light is thrown on the subject."

The last novelty is an electric egg-testing device, and consists of a box ornamented by velvet, rosettes, etc., and provided with two holes. In a corner inside the box is fixed a mirror at 45deg. A small electric lamp is fixed outside the box in such a manner that it throws light on the egg placed in the hole in the top of the box. Through another hole or aperture you can see through reflection on mirror whether the egg is translucent or not. Of course, the idea is based on the well-known fact that if you hold a bad egg opposite strong light of a lamp, etc., you can see black stains or streaks inside it. A good egg is translucent or partly transparent.

Though my above little inventions are not of much practical value, there are, I believe, a few readers of the *Electrical Engineer* who would try novel original ideas.

I may add that the simplest and best method to demonstrate the well-known Newton's law—viz., that white is a mixture of all known colours—consists in fixing a small paper disc with many coloured segments on it to a spindle of a small electric motor. During the quick rotation of the disc you see a perfectly white disc, which proves Newton's theory. If on the disc are drawn thick black lines and segments in a certain manner, and if opposite close to the said disc a small electric lamp provided with a reflector is placed, and you look at the rotating disc, a very queer phenomenon takes place—viz., if the disc is rotated in one direction you see red lines, if in another direction you see yellow or blue lines. In this manner you can produce an artificial rainbow out of white and black. The reversion of the motor could be made by a suitable commutator as used for the Ruhmkorff induction coil.—Yours, etc.,

A REMARKABLE ELECTROLYTIC PHENOMENON.*

Most metals, when used as positive electrodes in electrolysis, are either dissolved or corroded, producing metallic salts or oxides; but when used as negative electrodes, metals do not generally undergo such corrosion. They are seldom affected in any way, chemically, by the action of the current, and are never dissolved. It is to what appears to be an exception to this rule that I wish to call attention.

While experimenting some time ago on the oxidising effect of various electrolytes upon lead electrodes, I noticed, accidently, that under certain circumstances lead behaves toward some electrolytes in a very peculiar manner. The only conditions required are that the E.M.F. and current density shall be very high. On passing an electric current through a solution of disodium-hydrogen phosphate, between electrodes of sheet lead, I noticed nothing unusual during the experiment. The solution had a very high resistance and very little current passed even with a high E.M.F. At the close of the experiment, there being no switch in the circuit, the current was interrupted by lifting one of the electrodes out of the solution. It happened to be the negative electrode. At the instant of final contact between the electrolyte and the lowest point of the electrode as it left the solution, I noticed what appeared to be a cloud of black smoke or precipitate which had suddenly formed in the solution. On examining the cloud more particularly, and repeating the experiment several times, I found that by exposing only a very small surface of the negative electrode to the solution, there was produced a voluminous cloud of dark-blue or lead-coloured precipitate, which rapidly sank in the solution and rendered it entirely opaque.

It was then observed that the lead cathode was being rapidly eaten away, and that the precipitate was being produced at the expense of the lead. The precipitate was collected on a filter, washed with water and alcohol, and dried. It was found to be an impalpable powder resembling lead, and permanent in the air at ordinary temperatures. When rubbed in an agate mortar it was reduced to a lustreless gummy mass, but did not assume a metallic appearance. Heated to the melting point of lead in the open air, it suddenly absorbed oxygen and formed yellow plumbic oxide, with incandescence. Heated in a glass tube, in absence of oxygen, it melted to a globule of metallic acid.

In this bottle I show you a sample of this product that has been preserved more than two years without any apparent change.

The surface of the lead cathode, after the experiment, exhibited a peculiar appearance. It was reduced to a point at the end, and presented a smooth, shiny surface, like polished lead. It was of the form we should expect to find a positive electrode of copper or other soluble metal.

Other electrolytes were tried, and it was found that the lead precipitate could be produced in some solutions, but not in others.

The precipitate could not be formed in solutions of metallic salts from which a metal can be deposited by electrolysis. It cannot be formed in strong acids having a great affinity for lead. With ammonium oxalate and a positive electrode of platinum, there was formed on the platinum wire what appeared to be a deposit of lead peroxide, although no lead was originally in the solution. In a recent experiment I failed to produce this result.

Similar experiments were made with negative electrodes of iron, zinc, cobalt, nickel, manganese, magnesium, aluminium, copper, cadmium, silver, gold, platinum, bismuth, arsenic, antimony, and tin. Of these, arsenic alone acted in a manner somewhat similar to lead, being rapidly disintegrated as a negative electrode. The surface of the metal where the action took place was smooth, bright, and rounded, apparently polished. A film of brown, solid arsenic hydride was formed, which, instead of sinking, floated away from the electrode in straight lines on the surface of the solution. This hydride was also produced electrolytically by Sir Humphrey Davy. With lead electrodes, in a solution of sodium phosphate, some hydrogen phosphide was produced along with the lead precipitate. With borax and lead electrodes, the lead precipitate was formed very rapidly; and when the negative electrode was held close to the side of the glass beaker a bright reddish-brown stratum of liquid was seen to be continually formed at the surface of the electrode. This disappeared almost instantly after moving away from the electrode, but was continually formed as long as the current was strong enough to produce the lead precipitate. The addition of acetic acid did not prevent this formation.

Sodium thiosulphate gave a deposit of sulphur at the positive pole, confirming the theory that in the thiosulphates one atom of sulphur is electro-negative, and takes the place of an atom of oxygen in the sulphates. With sodium sulphite, sulphur dioxide was liberated at the positive plate. Strontium nitrate, instead of giving the lead powder, gave a blue flame around the point of the lead cathode.

These results seem to indicate the possibility of obtaining, by the use of high E.M.F. and high current density in electrolysis, products of an entirely different nature from those of ordinary electrolysis.

* Abstract of a paper read at a meeting of the Electrical Section of the Franklin Institute by Mr. C. J. Reed.

REDUCING THE COST OF ELECTRIC LIGHT.*

BY NELSON W. PERRY.

(Concluded from page 455.)

What promises to be a better method is one that has been tried on a small scale abroad, but not yet to any extent in this country—viz., encouraging the use of current during the hours of light load by reducing the price of service during those hours. The central-station manager could well afford to reduce his price to a mere fraction of what he now charges, if by that means he could obtain a steady demand for his product throughout the 24 hours.

Mr. H. Ward Leonard, who has given this subject more study perhaps than anyone else in this country, said in a paper recently read before the American Institute of Electrical Engineers: "If central-station companies would offer such a discount due to load-factor as to warrant their individual customers in installing at their own expense a storage plant which they could charge at the minimum rate per kilowatt-hour, and then use this stored energy to supply their occasional demands, I believe it is possible that the central-station companies, the storage battery companies, and the consumers might all derive a profit from the arrangement. I have no doubt that a central-station company could afford to make a rate of four cents per kilowatt-hour for a continuous service night and day, and make a satisfactory profit, while it would surely lose money in supplying an elevator at 15 cents per kilowatt-hour." If electrical energy were supplied to a customer at the lower figure, it would mean electric light at about $\frac{1}{6}$ cent an hour instead of 1 cent as now charged, or $\frac{3}{4}$ cent for gaslight, where gas costs 1·50dol. per 1,000 cubic feet.

In this connection he gives the following schedule of rates which he thinks should be charged per kilowatt-hour to customers, according to the proportion of the 24 hours they use current, together with the resultant gross income that these charges would bring into the central station:

Load-factor.	Rate per K.W. hour in cents.	Resultant gross income per annum per K.W. of plant.
5	30	$131·40
10	20	175·20
15	16	210·24
20	13	227·76
25	11·2	245·28
30	10	262·80
35	9·2	281·07
40	8·5	297·84
50	7	306·60
60	6	315·36
70	5·3	325·00
80	4·8	336·38
90	4·4	346·89
100	4	350·40

It will be noticed that, although when the customer uses current but 5 per cent. of the time (which is better than the average of electric light consumers) he is charged seven and a half times as much per kilowatt-hour as when

* From the *Engineering Magazine*. New York.

Digitized by Google

using it continuously, the gross income to the central station is only about one-third what it is from the lower figure. Or, in other words, the central-station company would, according to these figures, get a gross return nearly three times as great by selling its current to a customer who would take it constantly at a rate of ⅛ cent per lamp per hour than it would get from the customer who used his light but 1½ hours per day, and who paid it at the rate of 1¼ cents per lamp per hour.

Doubtless some such arrangement as here suggested will in time be resorted to in this country to the advantage both of the consumer and the manufacturer.

Then there is another method by which relief may be obtained—viz., by finding some by-product for the central-station man to manufacture during the hours of light load. I use the term "by-product" advisedly, for it must be something whose manufacture may be stopped the moment the machinery is required for the main business. The manufacture of ice is one such "by-product" that has found some favour among central-station men; but while this may give employment to boilers and engines during the daytime in summer, the dynamos are lying idle even during the few months when there is a demand for ice, and during the winter months such a plan would afford no relief whatever. It would be far preferable if some electrical product could be found, for this would give employment to all of the machinery at all times of the year when not otherwise required. This, in fact, is the invention which is most required at the present day, and seems more possible of attainment than any other form of relief thus far suggested.

One of the recent products of the electrical furnace that looks promising for this purpose is calcium carbide—a product not new to chemistry, but new to commerce. This substance, which is produced by the fusion of lime and coal dust in the electric arc, when decomposed by the simple addition of water gives rise to acetylene gas—one of the most highly luminous gases known, as well as possessing the highest calorific powers of any of the hydro-carbon gases. We, on this side of the Atlantic, have been rather sceptical as to the advisability or practicability of undertaking the manufacture of calcium carbide, but the proposition has been given a standing which at least makes it worthy of consideration by our continental friends who are about to undertake it. It seems that a company has actually been formed in Germany for this purpose, known as the "Gesellschaft zur Verwerthung von Acetylen-gas." That this is no mere haphazard, ill-digested concern is evidenced by the fact that the great German electrical concern of Siemens and Halske has taken a substantial interest in the project. Should the undertaking prove a commercial one, it will be of the utmost import to the central-station man, and the outcome will be awaited with the greatest interest.

The commercial status of the manufacture remains, however, to be proved. There are two other products, however, already objects of commercial manufacture, whose status is already determined. One of these is aluminium and the other carborundum. These articles are already being manufactured on a large scale, and their manufacturers are seeking cheaper power at Niagara to enable them to increase their outputs at lower figures. The question arises, Would it not pay the central-station man to manufacture these products during the hours of light load at a figure with which even the cheap water powers at Niagara could not compete, if by this means he could keep all his apparatus occupied at its best rate throughout the 24 hours, and thereby reduce the cost of his electric light by from 50 to 75 per cent.?

As indicating the cost of power in ordinary practice when it is produced in a fairly continuous manner, I may cite the case of the Chelsea Jute Mills, of Brooklyn, which, during a period of six days, while developing an average of 653·3 i.h.p., consumed but 1·482lb. of coal per indicated horse-power per hour. This is equivalent, if we assume a combined engine and dynamo efficiency of 81 per cent., to a consumption of 1·83lb. per electrical horse-power hour.

During this time the load was by no means constant, but varied between 495·21 h.p. and 764·96 h.p. The equipment consisted of Corliss compound condensing engines and vertical tubular boilers, and was in operation 10 hours each day. The figures given cover the whole amount of fuel used, including banking, etc. Most of our modern electric lighting stations have quite as good an equipment as this, and yet statistics show that the best of them average 7lb. to 8lb. of coal.

The demand of the day, therefore, is not better dynamos, better engines, better boilers, or better methods of transmission, but steadier jobs for the apparatus we have, and he who will invent that job will do a better service to the electrical industry than he who invents a new electrical system.

INSTITUTION OF ELECTRICAL ENGINEERS, Apr. 25.

SIR DAVID SALOMONS, Bart. (Vice-President), in the chair.

At last night's meeting of the Institution the following candidates were balloted for:

Member.—Francis George Hart, 28, Victoria-street, Westminster

Associates.—Joseph N. Atkinson, 14, Cornwall-street, St. George's-square; Henry Brazil, care of Messrs. Siemens Bros. and Co., Woolwich, S.E.; Arthur Edward Hadley, "St. Kilda," The Ridgway, Wimbledon, S.W.; William Henry Nimmo, Melbourne, Victoria; Henley Phillips, 102, North End-road, West Kensington, W.; Sydney Louis Rhys Price, Faraday House, Charing Cross-road, W.C.

Student.—Harry Hughes Harrison, 55, Roxwell-road, Shepherd's Bush, W.

The following paper was then read on

A MAGNETIC TESTER FOR MEASURING HYSTERESIS IN SHEET IRON.

BY PROF. EWING, F.R.S., MEMBER.

Makers of transformers are now generally alive to the paramount importance, from the point of view of all-day efficiency, of using iron in which the hysteresis losses are small. The need, however, is felt of some simple means by which this quality can be readily determined. Tests made by the ballistic and other methods have shown that different samples of iron may exhibit extraordinarily wide differences in regard to hysteresis. The author has found, for example, in the course of his own tests of iron supplied for transformers, a range of nearly three to one in the hysteresis of good and bad samples. It is unnecessary to point out how much the all-day efficiency of a transformer working under ordinary conditions will be affected if the sheet iron used in its construction has three times as much hysteresis as it need have. Again, experience shows that even in one batch of plates of the same rolling so much difference is apt to exist between one plate and another as to make the testing of a single sample furnish a poor guide to the average quality of the batch. Even in a single plate samples cut from different parts show marked differences in hysteresis. The author has noticed as much as 15 per cent. variation in samples taken from the four corners of a plate not quite 2ft. square, the material of which was of very excellent quality. It is well known that different analyses of the nearly pure iron of which such plates are rolled exhibit corresponding variations. The impurities appear to be unequally distributed; and, further, it is not unlikely that the irregularities which are found in the magnetic quality depend in part on slight differences in the treatment as regards annealing. Whatever their cause, there can be no doubt that they exist, and their existence makes the result of a single test often somewhat fallacious. What is wanted is a sufficiently large number of tests, in any one batch of iron, to allow a fair average to be estimated for the quality of the batch.

To make this possible a simple and expeditious method of testing is imperative. The ballistic method, although unimpeachable on the score of accuracy, is anything but expeditious, and can scarcely be called simple. The value of the hysteresis is arrived at by first observing the relation of the induction, B, to the magnetising force, H, for a consideral number of points in each of a series of cyclic processes of magnetisation, then drawing the B H curve for each of these cycles and measuring the enclosed area. The operation requires some skill and experience, and a good deal of patience. The same criticism applies to other methods of finding the hysteresis by first finding the relation of magnetism to magnetising force—as, for instance, by the permeameter or by the author's magnetic curve tracer. It must be borne in mind that in the testing of transformer iron the permeability is a quite secondary matter. What is of primary importance is the hysteresis, and high permeability is not necessarily or invariably found associated with small hysteresis. In the testing of sheet iron by the ballistic method the finding of the relation of B to H is a step in the process; it is not the object of the test.

These considerations have led the author to devise an apparatus which measures the hysteresis directly by a single

Digitized by Google

operation, and in a manner sufficiently simple to allow the test to be applied to numerous specimens without much expenditure of time, trouble, or iron. The basis of the instrument is the mechanical measurement of the work done in causing reversals of magnetism to take place in the iron under examination. Such measurements have been made before as a laboratory experiment and under special conditions. Thus Mr. L. R. Wilberforce and the author two or three years ago endeavoured to determine the hysteresis of a cylinder of iron when rotated in a strong magnetic field by measuring the couple required to keep it slowly turning; and a method of the same general character has been employed with complete success by Mr. F. G. Baily to investigate the disappearance of hysteresis which takes place in such a cylinder when the field is made sufficiently strong—a matter of great interest in connection with the molecular theory of magnetism. In the machine now brought forward as a practical tester for workshop use the same mechanical principle is involved. The process of reversal, however, resembles that which occurs in a transformer rather than in a dynamo; the induction is caused to have practically the same value in all samples, and that a value appropriate from the transformer point of view; the sample is cut in a very simple form, and is arranged to be readily inserted and removed. The magnetism is reversed by turning a handle, and the result is given by the position of a pointer on a scale.

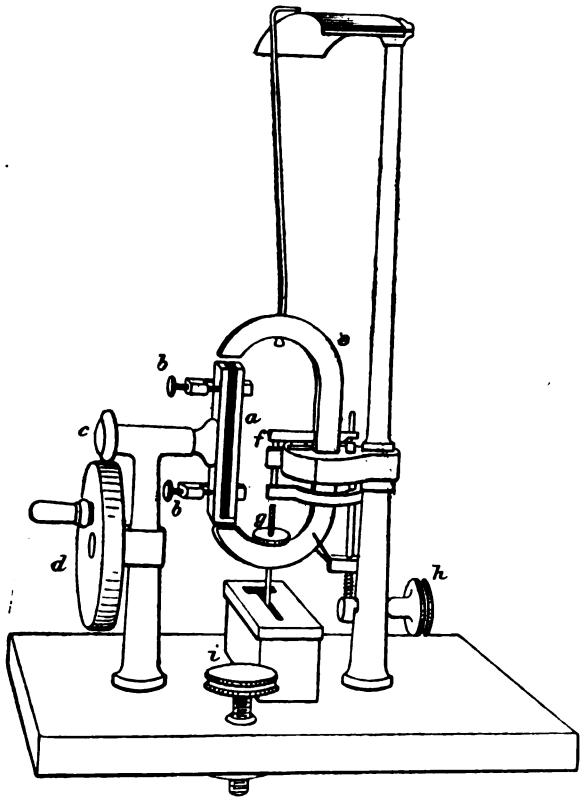

FIG. 1.

Fig. 1 is a drawing of the instrument now exhibited, the form of which has been reached after a good deal of experiment. The iron to be tested is cut or stamped in the form of strips, which are 3in. long and $\frac{3}{8}$in. wide in this instance. The number of these pieces that is taken to compose the sample depends on the thickness of the sheet; six or seven pieces will in general be sufficient for the usual gauges of transformer iron, and a smaller number if the material tested is the thicker sheet used in dynamo armatures. The bundle of pieces forming the sample is placed in a carrier, *a*, and is covered with a vulcanite washer and secured by two clamps, *b b*. The carrier is made to rotate by means of the friction pulley, *c*, and driving wheel, *d*. This causes the sample to revolve between the poles of the permanent magnet, *e*, with the effect that its magnetism is periodically reversed. The work done in reversing the magnetism, in consequence of hysteresis, causes a mechanical moment to be exerted by the revolving sample upon the magnet; and the magnet, being supported on a knife-edge at *f* in line with the axis of the carrier, tends to follow the sample and is deflected through an angle which serves to measure the work expended. Since a definite amount of work is done per reversal, whatever the frequency (so long as that is not so high as to make a sensible addition to the work by inducing currents), the deflection of the field magnet is independent of the speed at which the carrier revolves, and no special care has to be taken to turn the handle at a uniform rate. If the rate is very slow the magnet will show each individual impulse which it receives as the ends of the sample pass its poles, but when the speed is sufficiently raised these impulses blend into a steady deflection; and the speed may be further augmented, to the extent of doubling it, or more, without making the deflection change. It is only at higher speeds still that the effects of induced currents become apparent. The deflection is observed by means of a pointer and scale above the magnet. The swinging of the magnet is checked by means of a dash-pot below, consisting of a vane, or spade, moving in a box filled with oil. The stability is adjusted to give any required degree of sensitiveness by means of the weight, *g*, which travels as a nut upon a screw fixed to the magnet, and serves to raise or lower the centre of gravity of the oscillating system. The magnet swings about a knife-edge working in an agate trough, and a lifting arrangement like that of a balance is provided, operated by the handle, *h*, to save the knife-edge from unnecessary wear or injury. The pointer is set to zero in the middle of the scale by means of a nut which runs on a screw projecting sideways from the middle of the magnet, and a more delicate adjustment of the zero may be effected by means of the levelling screw, *i*. In operating, the observer inserts the sample and secures it by the clamps, then begins to turn the handle and lets the magnet down on its knife-edge. After reading the deflection of the pointer to one side he reverses the direction of rotation, reads the deflection to the other side, and takes the sum of the two readings as the total deflection. The deflection is proportional,

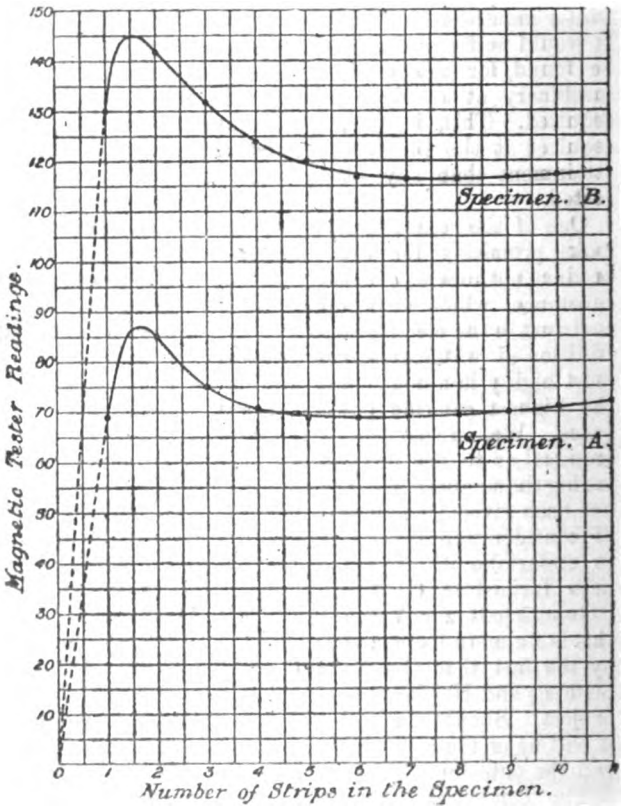

FIG. 2.

or very approximately proportional, to the hysteresis of the iron, even when samples widely different in quality are compared.

To secure that this shall be so, a considerable air-space is left between the magnet poles and the ends of the samples, with the result that such variations of permeability as are liable to be met with in different samples are almost without influence upon the total induction through the iron. The author has examined the induction by means of a search coil wound round the sample, and has found it to be practically the same in the best and worst specimens of transformer iron. The dimensions and strength of the field magnet are so proportioned, with reference to the section of the sample and to the extent of the air-gaps, as to make the induction have a value fairly representative of transformer work. In the instrument shown the induction is about 4,000 C.G.S. units with the normal size of test sample. By increasing or reducing the area of section of the sample the intensity of the induction is reduced or increased. Within reasonable limits, however, any value of this intensity may be adopted in testing, for it is known from the results of ordinary ballistic tests that curves drawn to show the relation of the hysteresis loss to B preserve their relative positions through a wide range of values of B. In other words, the relative amounts of hysteresis in different samples do not change, or scarcely change, when the iron is more strongly or less strongly magnetised. This, of course, follows from the fact that a formula of the type originally suggested by Mr. Steinmetz,

$$\text{Hysteresis loss} = c\,B^n,$$

is practically applicable, *c* and *n* being constants, within limits

Digitized by Google

which are more than sufficiently wide to include the inductions used in transformers.

In cutting the pieces which are to make up the sample care has to be taken to make the length always the same, otherwise the air-gaps, and consequently the induction, will vary irregularly. The carrier is formed so that it serves on a length gauge, and to facilitate the preparation of the samples a supplementary gauge is furnished in the form of a clamp of hardened steel, in which the strips are readily filed to the exact length after being cut a trifle too long. The width of the pieces requires no particular care.

The author was under the expectation that it would be necessary, in making an accurate comparison of quality between different specimens, to give the sample the same weight in each case in order to make it have the same cross-section. He finds, however, that no nice adjustment of the weight is required, provided advantage is taken of a property which will be most easily explained by citing an experiment made with the tester.

The experiment in question shows the effect of varying the section of the iron by varying the number of strips which make up the sample. Eleven strips of thin transformer iron were taken, each 3in. long by $\frac{5}{8}$in. wide, cut from the same plate. These were all used to form the sample in the first instance; then one was removed, and the remaining 10 were tested, then nine, and so on, until finally the sample under test consisted of a single strip. The following are the scale readings for this, and also for another exactly similar experiment, which was made with a different specimen of transformer iron, of a poorer quality than the first. The two specimens are distinguished as A and B:

Number of strips in sample.	Scale readings of magnetic tester. (Specimen A.)	(Specimen B.)
11	72	118
10	71	117½
9	70	117
8	69½	116½
7	69	116½
6	69	117
5	69	120
4	71	124
3	75	132
2	85	142
1	69	130

These results are also shown in the curves of Fig. 2. It will be seen that both curves have the same general character, and that the scale readings of the tester pass a very flat minimum when about seven pieces form the sample. Whether six, seven, or eight pieces be used, there is no material difference in the readings. Precisely similar results are given by other specimens. Hence, if a weight is chosen equal to that of seven pieces of this material as a general standard, it will suffice, in preparing other samples for test, to select that number of strips which will give a weight approximating even roughly to the standard weight. The nearest whole number of strips will do, and it is not necessary to cut a narrow or wide strip to make up the exact weight.

When only two or three strips of this thin iron are taken, the work expended in reversing the magnetism of the bundle is increased. The total induction through the sample is somewhat diminished, but the intensity is increased, and this more than compensates for the smaller volume of iron that is being operated on. It is only when the sample is reduced to a single piece that the saturation of the iron prevents B from increasing sufficiently to continue this effect, and there is then a sharp fall in the curve.

These considerations have led to the use of samples the aggregate thickness of which is equal to that of six or seven thin transformer plates. In testing armature plates the same weight is approximated to by taking a smaller number of pieces. It is scarcely necessary to add that solid pieces or bundles of wire may be tested as well as sheet iron.

Calibration.—An extensive series of experiments has been made in order to determine to what degree of accuracy the readings of this magnetic tester correspond to the hysteresis losses as found by ballistic tests for various samples of iron. For this purpose it was necessary to test each identical sample in as nearly as might be the same state, first ballistically, and then in the new tester. In view of the variations which are observed between one part of a plate and another, the author did not feel that it would be satisfactory to use separate pieces for the ballistic observations and for the observations to be made with the tester. After some consideration, he adopted the following two plans:

In the first place, the ballistic tests were made on rings, each consisting of a long strip cut to the width subsequently wanted in the magnetic tester—namely, $\frac{5}{8}$in. This was bent into a ring, the ends just overlapping. After bending, the ring was annealed in a gas flame to get rid of the hardness produced by the bending. This is a most essential step, for in good iron the process of coiling into a ring, even of large diameter, hardens the metal very perceptibly, and increases the hysteresis. Then the ring was tested ballistically, a sufficient number of cycles being taken to allow a curve to be drawn showing the relation of the hysteresis loss, or $\int H\,d\,I$, to B, from B=2,000 to B=8,000 or so. The same thing was done with each ring. Then the rings were uncoiled and cut up into 3in. lengths for the tester, and the pieces were straightened and annealed to get rid of the hardness due to this straining. The whole number of pieces into which each ring had been cut were then dealt out into packs of six (or five, or seven, according to the thickness of the material), and these packs were shuffled until repeated trials in the tester showed that every pack gave nearly the same scale reading. The mean scale reading for the several packs obtained from each ring was then taken as a mean applicable to that ring. Here it was assumed that the first and second annealings might be held to bring the material into the same physical state.

To guard against any uncertainty on this point, four additional trials were made, using a different procedure. Long strips were again cut, but each of them was tested ballistically in its original straight form in a solenoid with open ends, the induction coil being wound over the central region only. Each strip was 36in. long and $\frac{5}{8}$in. wide, and a single strip was used in each test. The general effect of the free ends is to shear over the B H diagram, but not to alter the enclosed area. Enough areas were measured to determine, as before, the curve of $\int H\,d\,I$ and B for each strip. The strips were then cut up into pieces for the tester, which were treated as in the former case. In this procedure there was no annealing.

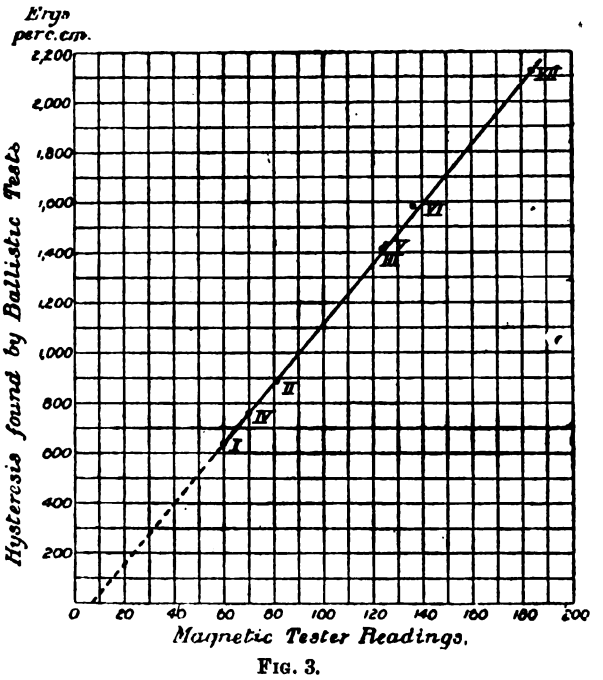

FIG. 3.

By these two means seven standard samples in all were produced of quality ranging from exceptionally good to exceptionally bad. The magnetic tester readings for these were taken, using approximately equal weights to form the sample in each case. In the following table the tester readings are given alongside of the value of the hysteresis loss ($\int H\,d\,I$) as determined ballistically for an induction, B, of 4,000 units for each of the seven specimens. Numbers I., II., and III. were those tested ballistically in the ring form; the others were tested in the form of straight strips.

Comparison of Magnetic Tester Readings with the Hysteresis Loss Determined by Ballistic Tests.

No. of specimen.	Magnetic tester scale readings.	Hysteresis loss by ballistic tests. Ergs per c.cm.
I.	60	640
II.	81	890
III.	124½	1,420
IV.	70	750
V.	125½	1,430
VI.	136	1,580
VII.	184	2,120

The same results are shown graphically in Fig. 3. It will be seen that they accord well with one another, and that the scale reading of the magnetic tester is nearly proportional to the hysteresis loss. A straight line drawn from the origin among the observed points lies sufficiently near all of them to allow the assumption to be made, so far as workshop testing is concerned, that the deflection in the tester, when multiplied by a factor depending on the sensitiveness of the instrument, is a practical measure of the hysteresis.

More exactly, however, the locus of the points is seen to be a straight line passing not quite through the origin. This

Digitized by Google

may be partly due to the fact that the induction produced in the tester is not absolutely so high in the bad as in the good iron. In all probability, however, it is mainly due to this—that as the sample revolves some small amount of work is done in periodically changing the distribution of magnetism in the field magnet itself, in addition to the work that is done in reversing the magnetism of the sample. Any work expended within the field magnet would contribute to the deflection, and would exist even if the sample (while retaining its permeability) were entirely destitute of hysteresis. Hence the line may be expected to pass a little to the right of the origin, as it is actually found to do.

It is intended to furnish with each instrument two standard samples of iron, along with a table stating their hysteresis as found by reference to ballistic experiments (in ergs per cubic centimetre, and also in watts per pound, at an assigned frequency). In proceeding to test other samples the operator will first note the deflection given by each of his standard pieces, and then, by simple proportion, or by aid of a diagram, he may go on to interpret in absolute measure the deflection observed with any specimen. This will make his results independent of any loss of strength on the part of the field magnet, or of any changes he may find it convenient to make in the sensibility of the instrument.

The hysteresis of the standard samples is stated for B = 4,000. To find the hysteresis for any other induction it is only necessary to use the following table of factors, which has been deduced by the author as a general mean from ballistic tests of many samples:

Induction, B.	Relative amount of hysteresis.
2,000	0·33
2,500	0·47
3,000	0·63
4,000	1·00
5,000	1·41
6,000	1·89
7,000	2·41
8,000	3·00

Other forms of the instrument can be constructed by making the field revolve while the sample is pivoted, so that the sample deflects; by placing the axis vertical instead of horizontal, with a control furnished by a spring or by bifilar suspension; by using a weighted arm or torsion head to measure the deflecting couple, instead of observing the deflection by a pointer on a scale, and so forth. But the author believes that the form now exhibited will be found both accurate and handy in general use.

He hopes it may contribute indirectly to the betterment of the iron used for magnetic purposes, by making it easy for a purchaser of iron or a purchaser of transformers to specify a maximum of hysteresis, and to see that he gets what he specifies. A notable improvement in the quality of sheet iron in this respect has been going on during the last few years, and it is now practicable to get iron which a short time ago would have been pronounced impossibly good. But it would be easy to quote tests showing that some iron of relatively very poor quality still finds its way into armature and transformer cores. The author's aim has been to put into the hands of those who are practically concerned with magnetic hysteresis, whether as makers of plates, builders of transformers, or engineers of alternate-current supply stations, an apparatus in which testing is reduced to its simplest terms, where each test consumes no more than a few square inches of the sheet, where the preparation and testing of the sample take only a few minutes of time, and the operation consists in turning a handle and reading how good or bad the iron is from the position of a pointer on a scale.

Discussion.

The **Chairman** stated that the paper would have been most welcome three or four years ago. The instrument would have been useful in laboratory work, but would be more so now to manufacturers. It would also be of value to the public as tending to cheapen the cost of current.

Prof. Fleming said it was impossible not to admire this simple solution of a practical question. The instrument had three merits—viz., that it was independent of steadiness; that it worked with small samples; and that the operation took a short time. These facts would make it very useful for workshop use. He wanted to know why the specimen was revolved instead of the magnet being revolved. An obvious modification was to make the field travel in various ways, though possibly this would not be an improvement. No one was much in love with ballistic methods, and thanks were due to Prof. Ewing for his invention.

Prof. Carey Foster echoed Dr. Fleming's thanks to Prof. Ewing. He thought, at first sight, that it would be possible to cause the magnet to move by rotating even a piece of wood, which would act as a fan. Possibly magnetic viscosity might act on the instrument in the same way as hysteresis.

Prof. Ayrton, with reference to the instrument, stated that he would like to learn if one wanted to know the hysteresis of different inductions whether it would work well. It should not be forgotten that hysteresis was not all that a designer of dynamos wanted to know, but permeability also, and it would not be a roundabout method to get at hysteresis by getting the permeability. Some years ago he had made a machine which allowed of the B H curve to be got quickly. He made a small separately-excited dynamo, using the specimen to be tested as the yoke, by which both the permeability and the hysteresis were obtainable.

Prof. Forbes congratulated the author on having produced an instrument which commended itself specially as a practical instrument rather than a laboratory one. The straightness of the lines in Fig. 2 were sufficient for all practical purposes.

Mr. Siemens said he had brought before the Institution in a paper some results by ballistic measurements, and he might get some of the author's measurements, but he thought he would stick, on the whole, to ballistic measurements. His reason was, that in testing for hysteresis, you should interfere with the iron as little as possible, whereas the specimens were filed for the author's apparatus. The instrument, however, was very handy, and likely to be extensively used,

Mr. Ferranti considered that the instrument would do well in engineering practice.

Mr. Esson said the machine was one which had been wanted for a long time, and only manufacturers could appreciate its value.

Prof. Ewing, in reply, thanked the speakers for their cordial appreciation of the instrument. He had, in his earlier experiments, found that to revolve the magnet was not the best plan, as the specimen did not always have the same stability. With regard to fan action, this did not exist, as might be seen by revolving the handle without any specimen or with a piece of wood. Eddy currents he had found to be of no importance, and the brass clamps were insulated with vulcanite. The machine was one primarily for the shop, but he disagreed with the suggestion that it was not also one for the laboratory. He used it himself in preference to the ballistic method for all except a comparatively small number of purposes. There would be many points enquired into when such a short and simple system could be used that would be left undone with the ballistic system.

THE USE OF ELECTRICITY FOR COOKING AND HEATING.*

BY R. E. CROMPTON.

Up to the present time, the utilisation of electrical energy, laid on now so universally in our houses for lighting purposes, for the further purposes of heating and cooking has been regarded by the public, and even by many who have technical knowledge, as impracticable, and certainly as too costly, to be adopted.

It will be my object this evening to show you that, far from this being the case, heating and cooking by electricity has now advanced to a highly practical and useful stage. No doubt these erroneous impressions have arisen chiefly from the fact that the advocates of electric lighting have from the first dinned into the ears of the public that one of the chief advantages of electric lighting is that by it light is furnished without heat; even those who put it more precisely showed that a 10-c.p. gas-jet heated the air of a living-room 13 times more than a 10-c.p. electric incandescent lamp, and it was the knowledge of these facts that prevented electrical engineers from carefully examining the problems connected with electrical heating.

However, at very early periods, Siemens showed that where intense heat is required to be concentrated in a small space the electric arc forms a very convenient furnace, and in many cases actually possesses economical advantages. This principle was practically adopted by Cowles for his earlier furnaces for reducing aluminium, and has been also used for electrical welding by the Benardos process.

But for the production of the heat we require for warming rooms or for cooking food little or nothing was done until about four years ago, for although Lane Fox was the first to point out, in his 1878 patent, that electrical heating could be satisfactorily carried out by placing the food or other materials to be heated in a vessel surrounded by a coil of insulated wire through which a current should be passed, nothing appears to have been attempted until about four years ago. Carpenter, in America, so far developed Lane Fox's ideas as to take out a patent for manufacturing electrical heating apparatus by attaching these resistance wires to the surface of cast-iron plates by an enamelling process, and a considerable amount of apparatus was manufactured by him in America on this principle; some of this was forwarded to England and was shown at work by Messrs. Crompton and Co. at the Crystal Palace Exhibition in 1891.

In practice it was then found that although Carpenter had done sufficient to show that electric heating could be usefully employed, yet that the apparatus at that time was not sufficiently durable to be of practical value. A number of serious defects made themselves evident, principally connected with the enamelling process; the enamel was found to crack, and the surface of the wire used was thus exposed to the oxidising action of the air. This action rapidly destroyed the wire, and thus broke the circuit.

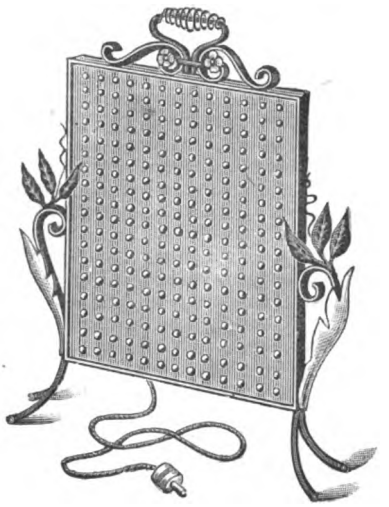
It occurred to us that this difficulty might be surmounted if sufficient time were spent on a research into the nature of the

* Paper read before the Society of Arts, April 24.

Digitized by Google

metals best suited to stand the frequent heatings and coolings to which the apparatus is subject, and which at the same time would have a coefficient of linear expansion so nearly the same as that of the enamels used, and of the plates to which the wires is attached by these enamels, that the tendency to crack which is caused by unequal expansion would be overcome.

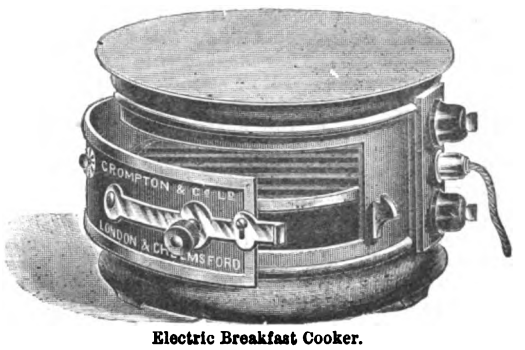
After a long course of experiments, we found that several of the nickel-steel alloys, varying in composition from pure nickel to others containing quite a large proportion of steel, were well suited for the purpose, and in all respects were far superior to the German-silver alloys which had been used in America. We also found that if we substituted for the homogeneous enamel used by Carpenter a composite enamel consisting of two or more layers, the lower one being of the hardest and most refractory character, we were able to obtain very satisfactory results. We have been able to use an enamel consisting



Electric Radiator.

almost entirely of silica for the groundwork—this fuses only at an exceedingly high temperature, almost approaching the welding point of wrought iron. We devised special machinery to artificially roughen the surface of the plates to which this first coat of enamel is to be applied, and we thus ensure that the layer of enamel between the wire and the plate to which it is attached is never even softened at the temperatures reached by our apparatus in ordinary working. We apply our nickel-steel wire in the form of a waved or crimped ribbon. This crimping is carried out by a special machine devised for the purpose.

This crimped ribbon is mounted on the surface of a "transfer plate," afterwards to be described, and it is from it transferred to the surface of the first coat of enamel, which has been already



Electric Breakfast Cooker.

raised to a temperature sufficient to soften it but not to melt it. We then cover the first enamel and the wire with powdered enamel of a more easily fusible nature, and we then raise the temperature of the whole to a sufficient degree to enable the second enamel to melt down and incorporate itself with the upper surface of the first coat of enamel, at the same time completely covering and insulating our wires. This process is one which has required much study and considerable manual dexterity on the part of the workmen, but once it was perfected it gave excellent results. It allows the wire to be heated to any degree desirable for ordinary heating or cooking operations without any fear of the enamel cracking so as to allow of access of air to the wire.

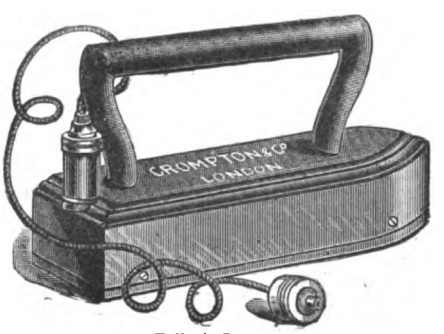
Not the least part of our difficulties was the preparation of the crimped wire and the designing of the transfer plates above referred to. We found that if we attempted to crimp the wire or arrange it in wavy patterns by hand that the wire was always liable to become thinner at each of the bends, and consequently the electrical resistance at these points was higher, and the heat developed greater, than that of the points intermediate between the bends. To avoid this, we had to devise a crimping machine, which crimped or corrugated the wire in such a manner as to avoid altering its cross-section. This machine takes the wire from a reel, crimps it, and delivers it in any desired pattern on to the surface of the transfer plates.

The transfer plates consist of a metal plate, to the back of which are attached a number of electromagnets in such a manner that when the crimped steel wire has been laid on its plate in any desired pattern or form, by exciting the electromagnets, they hold the wire and retain it firmly in position on the surface of the plate until it is desired to transfer it to the heated surface of the enamel; this can be done instantaneously by breaking the exciting circuit, so that the wire no longer adheres to the transfer plate. We have other methods of rapid transfer, but it is unnecessary to take up your time by describing them here, as the above method is fairly representative of the others.

By the above-described method we are able to apply the wire in somewhat complicated patterns to the surface of any metal plate, and to insulate it therefrom in a very thorough and permanent manner by our compound enamel. The only other difficulties which have arisen in connection with the enamel have been those due to unequal expansion and contraction of the terminals at the ends of the wire. At first we had some difficulty in arranging these so that the enamel did not crack, and allow the terminals to be burnt or oxidised at the point at which the wire leaves the enamel.

Electric Heater and Kettle.

The simplest form of apparatus in which we heat a plate by a current passing through a wire enamelled to its surface, is that which we call a heater. It is a cylindrical plate mounted on short legs, to the underside of which wire is applied and fixed by the enamel, the upper side being ground flat and polished. Such a heater can be put to many useful purposes: it can be used as a radiator of heat or as a means of heating dishes on the breakfast table, or for the purpose of drying linen or for warming or drying any article which it is inconvenient or dangerous to place near the fire. It can also be used for cooking purposes if the food is placed on flat dishes or pans, care being taken that the lower surface of the pan comes into close contact with the upper surface of the heater; but although cooking can be carried out in this manner, we do not recom-



Tailor's Iron.

mend the use of separate heaters, as there is always a loss from the lower surfaces of the pans not making sufficiently good contact with the upper surface of the heater, and we therefore prefer to ensure this contact by making the heating-plate form part of the kettle, saucepan, frying-pan, or other similar culinary utensil.

In the course of our experiments to determine the best and most efficient arrangements of our apparatus we met with great difficulties in what would appear a comparatively simple matter—the measuring of the temperatures we obtained. We found that the ordinary mercurial thermometer, however carefully it may be made, is not suitable for accurately indicating the temperature of the heated surfaces, as it really indicates the temperature of a stratum of air near to the heated surface instead of that of the surface itself. After trying Calender's improved form of the Siemens electric pyrometer, we eventually adopted for our measurements of temperature my own form of platinum thermometer, a description of which may interest you at this stage. This platinum thermometer, which measures temperature by showing the increase in resistance due to the rise in tem-

Digitized by Google

perature of a delicate coil or platinum spiral placed in close contact with the heated surface, is made and used as follows.

The spiral consists of a thin strip of platinum only two-thousandths of an inch thick by one twenty-fifth of an inch wide; a sufficient length of this strip to have about five ohms resistance at the temperature of 0deg. C. is wound in a form of double spiral on to a strip of mica sheet about ½in. wide by 4in. long; this is enclosed and held between two similar sheets of mica fastened together at their edges by a sewing of very fine platinum wire. The total thickness of the spiral and its covering is not greatly in excess of that of a sheet of paper, so that the whole of the spiral can be brought within a distance of one-hundredth of an inch from the surface to be measured. It is arranged on an electrical circuit in series with a standard resistance made of manganin. The standard made of this alloy has practically no change in resistance due to change of temperature—*i.e.*, within the limits of air temperature, change of an ordinary room, or laboratory. Both platinum spiral and the standard manganin resistance are provided with couplings or terminal screws, by which any desired number of platinum spirals may be coupled in series with the manganin standard. A very small constant current from an accumulator cell is passed through the whole of them. Each of the platinum spirals, as well as the manganin standard, is provided with a pair of potential terminals, and at the time of first calibration they are carefully adjusted, so that the potential difference measured on a potentiometer is exactly equal. When the platinum spirals are plunged in melting ice, and the manganin resistance is at the ordinary laboratory, it is convenient to balance them at this point at 1,000 on the potentiometer scale. The platinum spirals are then exposed to the temperature of boiling water in a hypsometer, and if the platinum employed be pure the potential difference of the platinum spirals, when now compared with that of the standard, will be as 1,362 : 1,000. If this portion of the potentiometer scale between 1,000 and 1,362 be divided into 100 parts, each of these will be equal to 1deg. C. It is evident that any desired number of temperature readings may be taken by employing a corresponding number of platinum spirals, and comparing them in turn with a standard.

It is obvious that this method of taking temperatures presents many advantages over the employment of ordinary thermometers, as when these have to be used for taking temperatures of ovens or of the interior parts of meat, or of other food, the act of removing the thermometers to take the reading introduces errors of considerable magnitude, whereas with the arrangement I have just described it is possible to take accurate readings practically simultaneously of the temperature in various parts of the oven or other apparatus, and of various parts of a joint of meat, and in this way a great many interesting facts respecting cooking have come to light. By these means we have been able to measure, with a high degree of accuracy, the amount of electrical energy that is required for various forms of heating and cooking apparatus, and the accompanying four tables give a fair idea of the cost of heating of surfaces required:

—	Time.	Energy in B.O.T. units.	Cost at 4d. per unit.	Temperature, Fah. scale.
	Min.		d.	Deg.
Table I.	—	—	—	50
Showing energy required to raise a heater plate from 50deg. F. to 400deg. F. in half an hour.	10	0·116	·46	257
	14	0·164	·67	332
	21	0·248	1·0	337
	30	0·404	1·61	400
Table II.	—	—	—	50
Shows the energy required for a radiator plate, such as we use for heating the air of a room.	10	0 091	0·364	171
	30	0·277	1·1	240
	40	0·350	1·4	257
	50	0·430	1·72	261
	60	0·500	2·0	264
Table III. Shows the energy required for boiling 1lb. of water in a tea-table kettle.	—	—	—	50
	18	·075	0·32	212
Table IV. Shows energy required by a smaller kettle containing ½lb. of water—*i.e.*, sufficient for two cups of tea.	—	—	—	50
	12	·051	0·2	212

First, for roasting, or baking, or frying; the second table gives the cost of heating surfaces to a lower temperature, such as is required for warming the air of a room, or for airing linen, or for similar purposes; Tables III. and IV. give the cost of the energy required for boiling water in small quantities, and are interesting, as they show that even when we are using electricity in the manner in which it compares least favourably with solid fuel—*i.e.*, for the boiling of water—we can, with an ordinary electrical kettle, switch on the current and obtain a cup of tea at a cost of less than a farthing for a single cup, or half a farthing per cup if several are required.

Although these tables show the amount and cost of electrical energy required to raise various kinds of heating surfaces to a certain temperature, something more than this is necessary to enable you to form an opinion of the value of heating and cooking by electricity from the point of view of economy.

When the subject is first mentioned even to a skilled engineer, his first idea is that in almost every case electric heating must be too expensive to become general. He knows the wastefulness of steam generating plant is such that not more than 6 per cent. of the heat energy in the fuel can be distributed to the consumer in the form of electrical energy, and he is not to be blamed if he concludes from this that there is no chance of using the reconverted heat from this energy, in competition with the heat which the consumer can obtain direct from burning the fuel itself. But the fact is that all these opinions are based on an insufficient knowledge of the economy—or rather extraordinary want of economy of cooking—as carried on at present by the ordinary kitchen grate. Now that we can actually measure the heat that is required, and carry on cooking operations, we are astonished at the smallness of the results obtained by present methods. The percentage of the heat units of the coal burnt in our kitchens which is actually utilised in cooking the food is in all private houses, and in most hotels and clubs, so ridiculously small that I should hardly be believed if I quoted you the figures which we have obtained; it is not too much to say that in many cases not more than 2 per cent. is utilised. This enormous waste is due to the fact that with the sole exception of boiling and stewing all the remaining operations of cookery depend on the radiation of heat to the substance to be cooked. Take, for instance, the process of grilling a chop. Consider how much coke has to be burnt before a bed of glowing coke fit for the purpose is obtained, and after the clear grilling fire is in order, consider that 70 per cent. goes up the chimney, 16 per cent. is radiated into the room, or employed in roasting the cook, male or female, as the case may be, and it is not difficult to understand that the chop itself does not receive more than 2 per cent. of the total heat units. On the other hand, with a properly-arranged griller heated by electrical means fully 65 per cent. of the heat energy in the electricity is utilised in the meat. Take, again, the case of the ordinary oven attached to the kitchener of a small private house. The oven may be used on an average three hours a day, but if solid fuel is used the oven must be heated continuously from the time that the kitchen fire is alight in the morning until late at night, so that in this case the total heat usefully radiated from the sides of the oven to bake, to roast, or brown the food within it, generally amounts to a very trifling percentage of the fuel used.

The comparison with gas cooking, although not so striking as when solid fuel is used, is still very favourable to electricity, for although in the case of the gas oven considerable economy results from the gas being used only at the time that the oven is required for cooking, yet in this case the heat is communicated to the food by radiation from gas flames, so that it is necessary that a current of air must continuously pass through the oven in order to ventilate it, and carry away the products of combustion. This ventilating current also carried away with it at least 80 per cent. of the heat units obtained by burning the gas.

The electrical oven consists, as you see, of a rectangular box, having double sides at bottom, top, back, and front; the inner surfaces of the inner plates are the electric radiators, and the space between them and the outer plates is filled with a non-conducting material; the door closes practically airtight, no ventilating current of air is necessary, thus all waste of heat being prevented. In this case, when the oven is filled with food, more than 90 per cent. of the heat energy can be utilised, and thus, although possibly 5 to 6 per cent. only of the heat energy of the fuel is present in the electrical energy, 90 per cent. of this—or 4½ per cent. of the whole energy—actually goes into the food, and thus the electrical oven is practically twice as economical as any other oven, whether heated by solid fuel or by gas. Thus far I have dwelt at some length on the economical question; it is time to say something on the questions of the convenience and of the superior results which can be obtained by the electrical means. I have already spoken of the large loss by radiation which occurs when solid fuel is used, or to a less extent when gas fuel is used; this has the great inconvenience of injuring the quality of food that is being prepared in the kitchen, of keeping the cooks in a heated and unpleasantly perspiring condition—and I might enlarge considerably on this point. The electrically-worked kitchen may be kept as cool as a dairy if it be desired, and the effects on the quality of the cooking, and on the health and tempers of the staff, must be experienced before it can be fully appreciated. I have also mentioned, in the case of the gas oven, the necessity for allowing ventilating currents of air to pass over the surfaces which are cooling. These

Digitized by Google

currents of air dry up and harden and take away the flavour of the outer portions of the meat; any connoisseur can detect this in the case of fruits cooked in a gas oven. With the electrical cooking, the absence of such ventilating currents and the stillness of the air prevents the above described drying and hardening action; the meat is found to be tender and juicy right up to the extreme outer surface, it is browned only to a sufficient extent to please the eye and the palate. Again, the facility for regulating the temperature to any degree of nicety which we can give with any of the electrical cookers or ovens, is being highly appreciated in the higher walks of the culinary art. Most skilled cooks will tell you that it takes much experience to satisfactorily manage an ordinary oven so as to bake or brown pastry or sweetmeats, and always give a uniform result. When these skilled cooks use electrical apparatus for the first time they almost invariably say, A child could learn the ways of this oven in a few hours and produce as good results with it, with absolute certainty, as I could with an ordinary oven after I had known it and learnt its ways for years.

All users of electric light are interested in the development of electric heating and cooking. You, all of you, have been told that the cost of electrical supply may be greatly reduced if it can be utilised during the daytime for other purposes in addition to lighting. Although the day may come—and I feel certain will come—that electricity will be used for power purposes within our homes to an extent undreamt of at the present time, yet such development must be necessarily of slow growth. We must be educated to the point of using power for many occupations and pursuits which have yet to be invented, but the day of electric cooking is not far distant. There is no reason why in a few years to come quite a majority of the users of electric light will do all cooking operations of the nature of roasting, baking, stewing, frying by electrical means—perhaps still employing solid fuel for boiling purposes only, and this in connection with a suitable furnace for supplying the whole of the hot water required for a household. Time does not allow me to go into very many interesting matters connected with electric welding, brazing, soldering, roasting of ores, drying of paints, and many other industrial operations in which electrical heating can be advantageously employed. I am also unable to do more than state the bare fact that the managers of several theatres—notably the Vaudeville—have found that electric radiators form a most convenient, safe, and economical method of heating the auditorium of a theatre. During the late severe frost these radiators were found to be a great convenience in large shop fronts to prevent the lowering of the temperature, and hence the freezing of the moisture on the plate glass, which otherwise obscured the contents of the windows. The apparatus, which is on exhibition in the room, is fairly representative of what is now supplied to the public.

DISCUSSION.

At the conclusion of the paper the author drew attention to the various exhibits, which included ovens, heaters, frying-pans, kettles, radiators, cigar-lighters, and a sealing-wax melter, the latter being described by Mr. Crompton as having been the last stronghold of gas in the City.

Mr. W. H. Preece, who occupied the chair, said he felt very much struck with the figures given as to the absolute waste of heat in our houses. He had been using many of the apparatus for some time, and found them very convenient. One electrical heating apparatus to which the author had not referred was the electrical poultice which Mr. Snaedeker, an American, had shown last year at the Royal Society. The speaker also referred to rail-welding, which he had seen in Boston.

Mr. Binswanger was thankful to Mr. Crompton for having taken up the subject of electrical cooking with such energy. The speaker could almost claim to have brought this branch of electrical engineering into England. Electrical cooking appliances not only performed their duties as well as others, but they had many advantages over the old-fashioned methods. He agreed with the author's figures, which would prove a lesson to electrical engineers.

Mr. Dowsing, after some questions had been asked, explained the nature of the ovens. They should not be used wastefully, like gas ovens. As regarded the electric heating of theatres, it was in itself dearer than ordinary methods, but it could be used more advantageously and a smaller quantity of heating was required. He doubted if electric radiators would compete with coal for a constant supply in big buildings, but they were cheaper than hot-water heating.

Mr. Crompton, in reply, said he believed that the apparatus now made was as durable as was desirable. He agreed with Mr. Binswanger that difficulties remained to be overcome in appliances where constant concentrated heat was required. With respect to the electrical poultice, he had experimented in that direction before the American gentleman made his appearance, but such appliances would only last a week or so. The success of electric cooking dated from the time of taking quantitative measurements. With respect to office heating, he believed radiators would be economical under certain circumstances.

At the conclusion of the proceedings the audience examined the apparatus exhibited, and consumed what had been cooked during the progress of the lecture.

COMPANIES' MEETINGS AND REPORTS.

METROPOLITAN ELECTRIC SUPPLY COMPANY, LIMITED.

The ordinary general meeting of this Company was held on Wednesday at Winchester House, Old Broad-street, Sir John Pender, M.P., occupying the chair.

The **Chairman**, in moving the adoption of the report of the directors, which was published in our last issue, said that he would first of all deal with the portion of the accounts which showed the growth of the undertaking. As long as customers continued to increase at their present rate and the areas occupied by the Company had to be filled up with the necessary networks of mains, expenditure on capital account for this purpose must continue to grow, while every addition meant the extension of profitable business. They had also expended on capital account £1,832 on buildings, £7,995 on machinery, and £2,703 on compensation. As regarded the expenditure on machinery, it was owing to new plant, which had been erected at Manchester-square station to meet the circumstances in which they had been placed in connection with the actions brought against them for vibration. It was impossible to carry out the remedial works without serious expense and great difficulty in maintaining a constant and regular supply, and, moreover, their working expenses showed a large increase in consequence of their other stations having been called upon to assist the Manchester-square works almost daily during the alterations. The machinery thrown out of use from these causes was doing excellent work elsewhere, so that they were now possessed of additional plant which it would have been in any case necessary to obtain to cope with their largely-increasing output. The item of compensation to which he had referred related entirely to payments made in connection with these lawsuits. The capital expenditure during the year naturally involved a provision of funds to meet it, and in dealing with this question the Board considered that they ought to be able to borrow on better terms than 5 per cent. In the result, a first mortgage debenture stock of 4½ per cent. was created to the extent of £250,000, of which £150,000 was issued last July at 105, that being the rate at which the old debentures had to be redeemed. This stock now stood at about 120. With the proceeds, the whole of the old debentures had been paid off, and the net premiums had been carried to the depreciation fund. Of the balance of £50,000 they had £21,000 in hand at the end of the year, but it would before long be necessary to make a further issue to keep pace with the rapid expansion of their business. Their revenue account showed a steady increase, being £16,150 more than in 1893, and the gross profits were £7,000 more. This improvement, satisfactory though it was, would have been larger had it not been for a somewhat heavy increase in working expenditure, partly owing to the higher price they had had to pay for coal, and partly also to the peculiar difficulties which the litigation referred to had forced upon them. The Board had also found it absolutely necessary to make certain reductions in favour of large consumers of current. While their receipts had thus been materially affected, the encouragement which this system of charging gave to use their current was beneficial as having a tendency to increase their day load. In one portion of their district also competition had to be met. After writing off the usual £1,000 from the preliminary expenses and setting aside a further £8,000 to depreciation, there remained a balance of £15,909, out of which they proposed to pay a dividend of 6s. a share and to carry forward £939. Referring to the amount written off for depreciation and the auditor's note on the subject, he stated that the Board did not in any way commit themselves to an opinion as to what amount should be written off on this account. Electric lighting was a business which was at present new and undeveloped. They had thought it best to err on the safe side, their desire being to make the foundation on which they built thoroughly sound. He was himself rather disappointed with the dividend, but when he saw the reasons for it he was satisfied that they were pursuing a sound policy. At the outset they anticipated receiving at least £1 a light, whereas the average sum they received was only 8s. 5½d. This, however, was not discouraging, owing to the growth of the Company. To-day they had about 224,829 lamps, and they had still a demand for 10,000, while, as far as he could see, with their present machinery they could go on to 300,000 lights. One reason for their not paying as large dividends as one or two other companies was that they had a much larger area, and had to lay down mains over a very considerable space. Great expense was incurred over these mains, but when they got a full demand for the light, having no increased expense, the Company would begin to reap what it was sowing at the present time. He therefore looked forward to the dividend steadily increasing. The demand was increasing, and they were building up the business on such a sound foundation that those who were in it now would have no cause to regret it. Their staff was highly efficient and well disciplined.

Admiral Sir G. H. Richards seconded the motion.

The **Chairman**, in answer to questions, said that their stations were very much inland, and this increased the price of their coal as compared with certain other companies who were more favourably situated in this respect. They were taking steps with the view of dealing with the competition they had to meet in one of their districts.

Mr. John Newton objected to the qualification in the auditors' certificate as to the accounts being correct "subject to the sufficiency of the charge for depreciation." He maintained that a company in its early stages which expended amply in maintain-

Digitized by Google

ing its machinery and property was satisfying all reasonabel requirements as regarded depreciation, especially where, as in the case of their Company, the business was rapidly expanding.

The **Chairman**, in reply, remarked that the auditors were appointed to represent the interests of the shareholders, and the qualification referred to in their certificate had probably been inserted in the interest of the shareholders. He believed, however, that the directors took very much the same view as Mr. Newton.

Mr. John Griffiths, of the firm of Messrs. Deloitte, Dever, Griffiths, and Co., the auditors, stated that the reason for wording their certificate as they had done was that they had no certain knowledge up to the present time of what the depreciation was. The motion was then adopted.

The retiring directors (Sir George Richards, Sir Eyre Massey Shaw, K.C.B., and Mr. John B. Verity) were re elected, as were the auditors (Messrs. Deloitte, Dever, Griffiths, and Co.).

COUNTY OF LONDON AND BRUSH PROVINCIAL ELECTRIC LIGHTING COMPANY, LIMITED.

The annual general meeting of the above Company was held at Cannon-street Hotel on Monday last, the Right Hon. D. R. Plunket, Q.C , M P., occupying the chair.

The **Chairman**, in moving the adoption of the report (which we published in our last issue), said that it was really the first annual report in the history of the Company, for though there was presented last October a statement of the proceedings up to that time, it was rather in the nature of an interim statement. Their present position was extremely satisfactory. To begin with, there was a credit balance of £332. 5s. 10d. While the capital expenditure had been proportionately heavy, there was nothing in that to be regretted when the purposes to which the expenditure had been applied were considered. Their financial position showed every symptom of being a thoroughly sound one. Before referring to the Company's experiences in the way of acquiring controlling interest in concerns outside the county of London, he would deal with their operations within that limit. As to these, undoubtedly they had met with a certain amount of delay, caused mainly by opposition from local authorities, not because of any defects in the plans which were submitted to them, but on account of accidents which had occurred with other systems; and in consequence of the representations made by the London County Council and other local authorities, the Board of Trade had hesitated to grant their approval to the system of supply proposed by the Company until possessed of the fullest information. They were carrying out their arrangements of treet boxes and such matters in a way which would fully meet all the requirements suggested in Major Cardew's last report. Already the County Council and the local authority of St. Luke and Clerkenwell had so far approved their plans that they had been able to lay the whole of their pipes for mains and to complete their arrangements for drawing-in boxes within that district, and at the same time they had begun the erection of their station at the City-road basin of the Regent's Canal. They hoped to be able to supply current from that station by the end of September next. In Wandsworth the work had been held back pending the publication of the usual Board of Trade regulations, but they hoped that these would now almost immediately be issued. The purchase of the site for a generating station was completed, the plans far advanced, and tenders would as soon as possible be invited for the construction of the buildings. Their application for a provisional order for the district of St. Olave's, Southwark, had received the consent of the local authority, and this district, which included the two London Bridge stations and railway approach, would be a valuable addition to their area of supply on the southern side of the river, as it nearly adjoined the district of St. George-the-Martyr, for which they held a provisional order, and instead of having separate generating stations for each district, one would be sufficient for both. Turning to the position of their undertakings outside the county of London, he would first take the case of Bournemouth, where they had acquired the interest of the Brush Company in the Bournemouth and District Company. Since the spring there had been a very substantial increase in the number of consumers, and it had been necessary to find an additional sum of money in order to provide further plant and mains as required. Upon the completion of the work now in progress. the Bournemouth station would have a capacity of 27,000 8-c.p. lamps. At Dover, the generating station buildings were now complete. Some of the plant was at work supplying the lamps on the sea-front with current, and the remainder would shortly be delivered. Mains had been laid throughout the whole business portion of the town and to the outlying district of Buckland. Next, as to Windermere, the consents of the whole of the local authorities for the lighting of whose districts they had sought a provisional order had been obtained, with the exception of two—viz , seven towns out of nine—and they were not without hope that the two which still stood out (Kendal and Ambleside) would consider it to their advantage to join the others. Finally, turning to Richmond, in Surrey, the negotiations had been completed, and they had now secured upon reasonable terms for themselves a controlling interest in the existing Richmond Electric Light and Power Company, which ought to have a rapidly increasing value. Already the lamp connections were equivalent to over 4,400 8-c.p. lights, and with small additional expenditure double the number could easily be supplied. The question of electric traction and tramways at various places had been brought under their notice, and was receiving careful attention.

The motion for the adoption of the report was seconded by **Mr. J. B. Braithwaite**, and carried unanimously.

The retiring directors, the Right Hon. D. R. Plunket and Mr. F. W. Reynolds, were re-elected. Mr. R. H. Marsh was also re-elected auditor for the ensuing year.

A resolution was afterwards proposed by **Mr. George Herring** for increasing the directors' remuneration as originally intended, but, after some discussion on the point, the motion was not pressed, Mr. Herring giving notice that he would bring forward at the next meeting a resolution with the object in question.

ORIENTAL TELEPHONE AND ELECTRIC COMPANY, LIMITED.

Directors: William Addison, Esq., chairman; B. St. John Ackers, Esq.; Henry Grëwing, Esq.; Thomas Lloyd, Esq.; George Bland Frost, Esq. Secretary: Alex. B. Chalmers, Esq.

Report of the directors for the period ended December 31, 1894, to be presented at the first annual general meeting of the Company, to be held at the Cannon-street Hotel, London, on Monday, April 29, at 1 p.m.

The shareholders will recollect that the Company was formed on March 12, 1894, to take over the property and assets of the old Oriental Telephone and Electric Company, Limited, the object in view being a rearrangement of the capital account of that company. In order to avoid any dislocation of the business and complexity of accounts, the latter have been continued as from December 31, 1893, the result being a net profit for the year of £8,729. 4s. 9d. As was intimated to the shareholders at the meeting held on March 12, 1894, a dividend on the present occasion can only be declared for the period from the date of incorporation of the Company to December 31, 1894. Under the advice of the auditors, therefore, the directors have apportioned £7,031. 4s. 6d. of the above sum as being the profit available for disposal. They propose to deal with this amount as follows: to write off £453. 17s. 10d., being the whole of the preliminary expenses incidental to the formation of the present Company, to pay a dividend at the rate of 4½ per cent. per annum, free of income tax, for the period from March 12 to December 31, which will absorb £5,871. 1s. 5d., and to carry forward £706. 5s. 3d. The general business of the Company has on the whole been satisfactory, and the electric lighting branch inaugurated by the old company shows prospects of assisting the revenue of the Company in the early future. The Bengal and Bombay Telephone Companies have paid improved dividends for the past year, whilst the Telephone Company of Egypt, the capital of which is almost entirely held by your Company, has made good progress. The accounts of the China and Japan Telephone Company have not yet been closed, but owing to the low rates of exchange ruling, the net revenue of that company, after payment of debenture interest, will show less favourably than in the previous year. Under Article No. 65 two directors retire at the present meeting, and these are Mr. William Addison and Mr. Thomas Lloyd, who, being eligible, offer themselves for re-election. The auditors, Messrs. Deloitte, Dever, Griffiths, and Co., appointed by Article No. 89, also retire, and offer themselves for re-election.

REVENUE ACCOUNT YEAR ENDED DEC. 31, 1894.

EASTERN EXTENSION TELEGRAPH COMPANY.

The report of the directors for the half-year ended December 31 last states that the gross receipts, including Government subsidies, have amounted during the half-year to £261,322, against £251,698 for the corresponding period of 1893. The working and other expenses, including £29,791 for cost of repairs to cables and expenses of ships, absorb £89,740, against £76,574 for the corresponding period of 1893, leaving a balance of £171,581. From this are deducted £4,584 for income tax, £31,895 for interest on debentures, debenture stock, and contribution to sinking fund, and £1,372 for celebrating the Company's twenty-fifth anniversary, leaving as the net profit for the half-year £133,729, which, with £68,457 brought forward from the previous half-year, shows an available balance of £202,186. One quarterly interim dividend of 1¼ per cent. has been paid for the half-year, and it is now proposed to distribute another of like amount on the 2nd proximo, making, with the interim dividends paid for the first half-year, a total dividend of 5 per cent. It is also proposed to pay a bonus of 4s. per share, or 2 per cent., making a total distribution of 7 per cent. for the year 1894. The balance of £89,686 has been carried to the general reserve fund, which, after being credited with interest received during the half-year and profit on sale of investments, and debited with £100,000, part cost of the new Singapore-Hong Kong cable, now stands at £641,598. In accordance with the provisions of the trust deed dated May 10, 1879, 389 of the Company's 5 per cent. Australian Government subsidy debentures, amounting to £38,900, were drawn by lot on the 1st inst. for payment at par on July 1 next.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Huddersfield.—The Electric Lighting Committee of the Town Council invite tenders for 2in. and 3in. cast-iron spigot and socket pipes. We have already given particulars. Tenders must be sent in by to-day.

Manchester.—The Lancashire and Yorkshire Railway Company require by the 30th April tenders for the supply of an oil-engine, engine packing, signal and telegraph fittings, signal, telegraph and electric light wires, wire, etc.

Brighton.—The directors of the Brighton and Rottingdean Seashore Electric Tramroad Company are prepared to receive tenders for the supply and maintenance of accumulators for an output of 35 e.h.p, at about 200 volts, for use on a large car. Particulars upon application to Mr. Magnus Volk, Madeira-road, Brighton.

Londonderry.—The Corporation invite tenders for the supply of carbons for one year from June 1, 1895. Schedules of quantities and further particulars may be obtained on application to Mr. John Christie, electrical engineer, Strand, Londonderry. Tenders, accompanied with samples, marked "Tender for Carbons," to be lodged with Mr. R. Chambers, town clerk, not later than May 1.

Brighton.—Notice is given that the Council of the borough will receive tenders from such persons as may be willing to enter into a contract for the supply and erection of boilers at the Corporation electricity works. The Council also want tenders for the supply and erection of arc lamps, switches, etc., and, thirdly, for the supply of indiarubber lead-covered armoured cables. Specifications can be obtained on application at the town clerk's office, Town Hall, Brighton. Tenders for the boilers are to be sent in by May 13; for the arc lamps, switches, etc., by May 27; and for the indiarubber lead-covered armoured cables by May 13.

Portsmouth.—Tenders are invited for wiring and lighting by electricity (1) the Corporation stables, Landport, (2) the fire brigade station, Landport. Full particulars can be obtained and the specification in each case may be seen at the Town Hall, where form of tender for each division of the work can also be obtained. Forms of tender supplied are to be completely filled in and sent under cover to Mr. Alexander Hellard, town clerk, by 10 a.m. on 29th inst. The form of tender will comprise an agreement to pay not less than the trade union rate of wage and to observe the hours of labour and conditions recognised and in practice obtained by the trade unionists in the borough.

Rangoon.—Tenders will be received by the president of the Rangoon Municipal Committee, not later than November 4, for the lighting of Rangoon by electricity. Tenders should be accompanied by detailed plans, specifications, and estimates, and must state the terms on which the installation proposed will be undertaken. All information regarding the existing system of lighting and the cost, etc., with plan of the town, can be obtained on application to Messrs. Ogilvy, Gillanders, and Co., Sun-court, 67, Cornhill, London, E.C., accompanied by a remittance of £1. 1s. Tenders are to be sent in sealed covers and endorsed "Tender for Electric Lighting, Rangoon." Mr. J. Short, Rangoon, is the secretary of the committee.

Manchester.—The Corporation invite tenders for the supply, delivery, and erection, complete, of the electric lighting machinery and installation for the efficient lighting of the new foreign animals wharf, situated at Mode Wheel. Copies of general conditions, specification, and drawing can be obtained on application to Mr. T. de Courcy Meade, city surveyor, Town Hall, Manchester, on payment of five guineas (which will be returned on receipt of a *bonâ fide* tender). Tenders, to be endorsed "Tender for Electric Lighting, etc., Foreign Animals Wharf, Mode Wheel," to be addressed to the chairman of the Markets Committee, and delivered at the city surveyor's office not later than 9 a.m. on Monday, May 13. The Corporation do not bind themselves to accept the lowest or any tender.

BUSINESS NOTES.

Western and Brazilian Telegraph Company.—The receipts for the past week were £2,808.

Hayfield (Stockport).—The Parish Council want to know the comparative cost of gas and electric lighting.

Kingswood.—A committee of the Urban District Council are considering the question of the introduction of the electric light.

Croydon.—A new theatre—the Grand—has been built here. Provision has been made for the introduction of the electric light later on.

Removal.—Mr. C. A. Clarke (Messrs. Mix and Genest, Limited) informs us that his address is now 37, Marshall-place, Cheetham Hill, Manchester.

Eastern Extension, Australasia, and China Telegraph Company.—The ordinary general meeting will be held on May 1 at Winchester House, E.C.

Electricity for Gold Mines.—The Forbes Reef Gold Mining Company, Limited, notify that the electric power plant to work the Avalanche Mill has started, and works well.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 21st inst. amounted to £1,386, as compared with £682 in the corresponding week of last year.

West India and Panama Telegraph Company.—Dividends of 6s. per share on both the first and second preference shares are recommended by the Board for the six months ended December 31 last.

Cheshire Electric and Steam Yacht Company, Limited.—This Company has been registered, with a capital of £2,000, to carry on the business of a shipping company in all or any of its branches.

Hull.—A Local Government Board enquiry was to be held last night by Colonel C. H. Luard, R.E, into an application of the Corporation for sanction to borrow £2,800 for an extension of the electric lighting plant.

Eastern Telegraph Company, Limited.—This Company announce the payment by warrants on May 1 of interest for the half-year ended April 30 on its 4 per cent. mortgage debenture stock. The transfer books will be closed from April 26 to May 1, both days inclusive.

Keswick.—A meeting of the Urban District Council was held last week at which a letter was read from the electric light company suggesting a meeting with the Council to-day (Friday). Mr. Hope moved that the letter be referred back to the committee, and this was agreed to.

Alternate-Current Electromotor Syndicate, Limited.—This Company has been registered with a capital of £6,000 to enter into an agreement with W. L. Davies for the acquisition of certain patents relating to improvements in electromotors, and to develop and to turn to account the same.

City and South London Railway.—The receipts of the Company for the week ended April 21 were £856, against £886 for the corresponding week of 1894, or a decrease of £30. The total receipts for the current period of the present half-year are £15,219 against £14,613 in the corresponding period of 1894, an increase of £606.

Digitized by Google

Perth.—The Police Commission have agreed to a recommendation of the water manager to light the waterworks with electricity at a cost of £80, with £12 annually for upkeep. The present gas bill amounts to £40 a year.

The City.—At Tuesday's meeting of the Commissioners of Sewers, the clerk read a letter from the comptroller (Mr. Brand) asking that Mr. Voysey, the electric light inspector, should be allowed to act as consulting electrical engineer to the Corporation at a nominal sum. The consideration of this matter was adjourned until the next court.

Stafford.—A meeting of the Town Council was held on Tuesday, when, in moving the adoption of the report of the Electric Lighting Committee, Mr. W. H. Peach said that the workmen would begin the laying of the cables in a few days, and that the committee were pleased with the way in which the tradesmen of the town were taking up the electric light.

Cheltenham.—As at present arranged, the formal handing over of the Corporation electric lighting station by the contractors, Messrs. Siemens Bros. and Co., will take place on Tuesday, 30th inst. Mr. Preece, F.R.S., has promised to take part in the ceremony, and it is also probable that Prof. Ayrton, Mr. Alexander Siemens, and Mr. Callender will also be present.

Liverpool.—The special committee appointed by the Corporation to negotiate with the Electric Light Supply Company in that city for the purchase of their undertaking as a going concern have practically arranged for its acquisition for £400,000. Before entering into a formal agreement, however, the committee have decided to obtain the services of an expert to examine the whole resources of the company.

Submarine Cables Trust.—The report of the trustees states that the accounts for the financial year to April 15, 1895, show that the revenue, including the balance of £240 brought from the previous accounts, amounted to £21,704. The expenses of the trust amounted to £1.194, and the payments on account of the coupons to £20,286, together £21,480, leaving a balance of £224 to be carried forward.

Belfast.—The Electric Light Committee of the Town Council have held a meeting under the chairmanship of Alderman Pirrie, J.P. The electrical engineer (Mr. M'Cowen) reported that some of the brass inspection plugs in the street boxes had been wantonly removed, either for mischief or for the value of the brass, and that the City Commissioner of Police had been requested to draw the attention of the constabulary to the matter with a view to the detection and punishment of offenders.

Barnsley.—A discussion has taken place in the Town Council as to what is to be done with the land in Kendray-street. Alderman Halton said that the Corporation had sold land in important thoroughfares before—notably the Three Cranes—and they must regret it now. Although he did not consider Kendray-street was the best site for municipal buildings, he thought that in the future when the town was supplied with electric light by the Corporation, this would be the centre for the electric light.

Greenwich.—The District Board of Works have received from the St. Paul, Deptford, Committee a report stating that they had considered a letter from the Vestry of St. Mary, Islington, who were of opinion that parliamentary powers should be obtained giving the Board of Trade or some other independent authority control over gas companies similar to that exercised over electric lighting companies. On the recommendation of the committee, it was resolved to inform the Board of Trade that the Greenwich District Board of Works concurred in the suggestion.

Cardiff.—At the Cardiff Council meeting on Monday, Councillor White drew attention to the minutes of the Lighting Committee, wherein it was stated that a discount of 25 per cent. should be allowed on the accounts for the electric light supplied to the Great Western Hotel in respect of lamps burning both day and night, and to similar discounts allowed to other consumers. The Mayor explained that the extra discount was given to encourage the use of electric light during the day. The discount might seem very heavy, but the interests of the town were protected.

Birmingham.—Mr. Frederick Herbert Tulloch, the inspector of the Local Government Board, held an official enquiry at the Guildhall, on Thursday last week, into the application of the City Council for sanction to borrow £20,230 for purposes of electric lighting. It was stated that the Local Government Board had already sanctioned the applications of the Council to borrow some £41,000. The further loan was required for additional work and extras, which were explained by the city surveyor. The proceedings were formal, and there was no opposition.

African Direct Telegraph Company.—Notice is given that, in conformity with the conditions upon which the issue of the 4 per cent. mortgage debentures was made, the fourth drawing for payment of these debentures, 115 in number, will take place in the presence of a notary public of the city of London, on Wednesday, May 1, at 3.30 p.m., at the offices of the Company, Winchester House, Old Broad-street, London E.C. Notice is also given that the second drawing for the 4 per cent. registered debentures (series B), 14 in number, will take place at the same time and place.

Wimbledon.—The Electric Light Committee of the Urban District Council have recommended that a fee of £50 be paid to Mr. Preece to prepare a plan for lighting the district by electricity. Mr. Neller suggested that Mr. Preece should be asked to also prepare an alternative plan for lighting the main thoroughfares only. There was a possibility that the cost of lighting the whole town by electricity would be more than the Council would be willing to bear. Mr. Crimp moved, and Mr. Crickmay seconded, that Mr. Preece first be asked to meet the whole Council in committee. This proposal was agreed to.

Great Northern Telegraph Company.—The total receipts during the year 1894, including the balance brought forward from 1893, have amounted to £386,438, and the expenses have been £78,962, which shows a net profit of £307,476. The following payments have been made: 5 per cent. interest on debentures, 1883 issue, £9,750; amortisation of 100 debentures, £10,000; amortisation fund, £27,777. The Board propose to place to reserve and renewal fund £83,333, to the pension fund of the staff £2,777, and to declare a final dividend, making, with interim dividends already paid, 8·60 per cent. for the year, carrying forward a balance of £43,170. 17s. 8d.

City of London Electric Lighting Company, Limited.—The revenue return of this Company for the quarter ended March, 1895, is as follow, the figures within brackets being those for the corresponding period of last year: revenue from sale of current for public lighting £3,191 (£3,100); revenue from sale of current for private lighting, etc. £26,622 (£12,460); estimated revenue from other sources £340 (£404); total, £30,153 (£15,964), being an increase of £14.189. The equivalent of 8 c.p. lamps connected on March 26. 1895, was 148,594, being an increase during the quarter of 13,134. The equivalent of 8-c.p. lamps connected on March 26, 1894, was 84,634, being an increase during the corresponding quarter of last year of 19,293.

Brighton.—At a meeting of the Lighting Committee of the Town Council held on April 8, the sub-committee appointed to consider the request of the Finance Committee for a contribution towards the cost of collection of rates in respect of the electricity charges reported that, having given the matter their full consideration, they were of opinion that a sum of £250 per annum should be paid from the electricity works account as a contribution towards the expenses of the rate collection, and recommended accordingly. The sub-committee also recommended that it be suggested to the Finance Committee that it was desirable that one collector should be permanently allotted for the collection of the electricity charges. The committee approved the report. On the motion of Councillor Stafford, these proceedings have been confirmed by the Town Council.

Luton.—A communication has been read at a meeting of the Town Council from Messrs. Sharpe, Parker, and Co., stating that a Bill to confirm the electric lighting provisional order was introduced into the House of Commons on April 4, and read a first time. A print of the Bill would be sent as soon as it came from the press. At the same meeting, with reference to the telephone wires, Mr. Wilkinson said it was necessary the public should be guarded against any dangers which might arise from the wires, and asked if it was possible for the Corporation to levy some kind of toll for the privilege of crossing the street, as that would enable them to exercise some control over the wires and test their stability if need be. The Mayor said the matter had not come before the General Purposes Committee, but doubtless when the town clerk returned he would take proper steps to protect their interests.

Folkestone.—The Town Council have received a long letter from the chairman of the directors of the Dover Electric Company, stating that the installation was now nearly complete and inviting the Corporation to inspect the works, promising to make arrangements for their reception and to afford every information as to the plant necessary to light Folkestone. The letter also intimated that the company could make arrangements to light Folkestone and give very advantageous terms. Alderman Sherwood remarked that there were three committees appointed. He suggested another, to which that letter should be referred. Councillor Thompson moved that the letter be received and that the invitation be accepted. It would be a very good thing, especially for Mr. Baker's committee, for as far as he could learn, they knew nothing yet about electricity. Councillor Tolputt seconded, and it was carried.

Great Northern and City Railway.—In connection with the private Bill of this Company there has been considered before Mr. Campion, one of the parliamentary examiners, a petition for an additional provision to the Great Northern and City Railway Extension of Time Bill. The petition stated that the Great Northern Company had decided to rearrange their Finsbury Park Station to enable the trains to run into that station instead of Drayton Park as originally proposed; and, as it was desirable that the same locomotive power should be used, power was asked to use steam as the motive power on the City line in addition to or in substitution of electricity, as at present authorised. The Metropolitan Railway Company objected that the standing orders had not been complied with, as the notices for the Bill did not include the substitution of steam as one of its objects, and the examiner upheld their contention, and reported that the standing orders had not been complied with. The question will subsequently be dealt with by the Standing Orders Committee.

Bath.—Alderman Sturges, at a meeting of the Surveying Committee, has brought up the electric light bill for the last quarter, amounting to £563, but £30 was deducted for fines, and Mr. Sturges moved that £10 be omitted from the fines owing to exceptional circumstances. The proposal to reduce the fines was carried. To the Town Council, sitting as the urban sanitary authority, Alderman Sturges has presented a report from the Lighting Committee with regard to the application of the electric lighting company for a provisional order and the counter-application of the Corporation. The alderman explained that the committee declined to accept the suggestion of the Government inspector, that the authority should consent to the company

Digitized by Google

having the order upon condition that certain clauses were inserted in it giving the authority the power of purchase. After some discussion the following resolution was adopted: "After very carefully considering the report and deliberating upon the concluding suggestions contained in it, your committee are still unanimous in their desire to obtain a provisional order according to the decision of the authority on January 14 last."

Bournemouth.—A meeting of the Vestry of Holy Trinity Church has been held, at which the Vicar asked if General de Vitre could give them any information with regard to the cost of the electric light and the gas. General de Vitre cited two years by way of example with regard to gas. In the first of those two years the cost of the gas was £38. 4s. 5d.; in the next £39. 6s. 10d. Those amounts did not include the cost of repairs. The average cost of gas had been £38. 15s. The electric lighting had been supplemented to some extent by gas for heating the church. For example, during the first complete year in which they had the electric light the gas used cost £2. 16s. 3d., and in the following year £4. 1s. 10d. The electric light for that first year came to £34. 17s. 6d., and adding the £2. 16s 3d., the total was £37. 13s. 9d. In 1893-4 (which was the next year) the electric light bill was £26. 4s. 3d., and adding the £4. 1s. 10d., the total came to £30. 6s. 1d. Last year the total for electric light and gas was £32. 9s. 10d. The average cost per year for electric lighting, including also the gas used, was £35. 10s, so that the electric light bills, even including the gas used, had been less than the bills for gas lighting.

Aberdeen.—An extensive installation of the electric light has just been carried out in the police and municipal departments of the Town House. Altogether about 200 lamps are used, the power varying from 8-c.p. incandescent to 2,000-c.p. arc. The buildings have been divided into sections, so that each department may register its own consumption, and there is also a subdivision of sections by which it is made impossible, in the event of an accident, for the whole of the lights in a room to go out at one time. In the Town Hall the arrangement of the lamps has been carried out very effectively, 34 incandescents being placed on the ornamental bosses of the roof. Each lamp is of 25 c.p. The work has been carried out by Messrs. New and Mayne, electrical and general engineers, 6, Schoolhill. All the wires have been laid and the walls pierced without the slightest damage having been done to any of the decorative painting. It was no easy task to accomplish this so successfully. At some places the wires had to be taken through blocks of masonry about 5ft. or 6ft. thick, and in other places, to prevent the breaking of plaster, the wires had to be carried along very circuitous routes. In one case, indeed, about a quarter of a mile of wire was utilised in supplying a current to a bracket only a short distance from the street main.

Hammersmith.—The committee of the Vestry appointed to consider the question of electric lighting have reported having viewed various sites for a generating station, and recommended the Vestry to treat for the purchase of two pieces of land abutting upon Fulham Palace-road, known as the Gardens Estate, belonging to Miss Yeldham and the Latymer Foundation, for the sum of £7,000. Mr. Searle, as chairman, moved the adoption of the recommendation. He wished to thank Mr. Rawley Cross for his assistance in trying to select another site. Mr. Greig moved a reference back to the committee to consider a suggested site in Uxbridge-road. Mr. Glasier supported the committee's report, remarking that it was a great convenience to have the station near the wharf. The cartage of coal was a serious thought, and the nearer the wharf could be to the station the better. Mr. Payne advocated a more central station. He suggested that advertisements be issued calling for offers for the sale of land in different parts of the parish. Mr. Bendon thought the Vestry would be acting indiscreetly if they did not embrace the offer of Miss Yeldham and close the bargain. An amendment by Mr. Greig that the matter be referred back to the committee only received three votes, the other members voting for the recommendation, which, of course, was agreed to.

Pemberton.—The chairman of the District Council, at a meeting of that body, drew attention to the request of the Pemberton Electric Lighting Company for the permission of the Urban District Council to lay down and work plant for the supply of electric light to the whole or any portion of the Pemberton township. Mr. Clayton thought that by allowing the electric lighting company to step in the Council would be practically selling its birthright. The Chairman poiated out that they had power to buy them out. Mr. Clayton referred to mistakes the Pemberton Board had made in the past. One was that they allowed the gasworks to slip through their fingers, and the other that they fought the battle of the waterworks, whereby they lost something like £30,000. They ought to be very careful in the matter now before them ere they consented, in any shape or form. Mr. Cheetham thought when the present scheme was put before them that if they, as a Council, were not prepared to go on with it, let them try what private individuals would do. He moved that, subject to satisfactory conditions being arranged, the consent of the Council should be granted to the proposed Pemberton Electric Lighting Company, Limited, to light the whole or such portion of the district of Pemberton with electricity as the proposed company might think fit. The motion was carried. A committee was appointed to deal further with the matter.

Ford-Lloyd Manufacturing Company.—The affairs of this Company came before Mr. Justice Vaughan Williams on Wednesday. The action of Grove *v.* Ford-Lloyd Manufacturing Company, Limited, was a motion for judgment in the usual form against an electrical engineering company, in default of defence. The Court had granted a winding-up order, and the official receiver was not represented. Plaintiff was a holder of £1,000 debentures, in regard to which default had been made through non-payment of interest, etc. His Lordship made a compulsory order, and continued the official receiver as liquidator of the Company. The creditors and shareholders of the Company met at the Board of Trade offices, 33, Carey-street, when Mr. G. S. Barnes, official receiver, stated that the Company was formed in June, 1893, with a nominal capital of £10,000, to acquire the business of electrical engineers and manufacturers carried on by the Ford-Lloyd Manufacturing Company, with the sole right to dispose of the invention known as the "E. S. Dry Battery." The failure of the Company was attributed to the want of sufficient capital to work the business. The accounts filed showed unsecured debts, £977; liabilities on bills discounted, £927; loans on debenture bonds. £3,000; and preferential claims, £120. The assets, valued at £1,631, were fully charged to secure the loans on debentures. No liquidator was nominated, and the case was left in the hands of the official receiver.

Medical Electrical Institute.—The affairs of this concern have been up again in the Courts. This company was formed last October to take over the business hitherto carried on by the Medical Battery Company, Limited, which went into liquidation in November, 1893. The capital was agreed at £75,000, of which £50,000 ordinary shares were to be issued as fully paid to the shareholders of the old company, and £25,000 preference shares were to be issued to the creditors of that company. No shares had been allotted under that arrangement, the company being unable to carry through the reconstruction scheme to completion. First debentures to the amount of £2,790 had been issued, and others were to follow, forming a charge of £6,650 upon all the assets of the company. In January last a receiver was appointed on behalf of the debenture-holders, and recently a winding-up order was made against the company. At the meeting of creditors and contributories held before Mr. C. J. Stewart (official receiver) no resolution was moved for the appointment of a liquidator, and the matter was left in the hands of the chairman to be wound up in the usual manner. The accounts filed under the proceedings showed unsecured debts £1,363, other liabilities £648, loans on debenture bonds £9,440, and preferential claims £186. The assets are valued at £6,000, and are covered by the debenture bonds, the deficiency to the creditors being £5,680. In reply to a creditor, the chairman said there was no prospect of any dividend being paid on the unsecured claims, which included a sum of £250 in respect of directors' fees. Nothing whatever had been received by the directors.

Worcester.—The City Council having applied to the Local Government Board for sanction to a loan of £20,230 for purposes of electric lighting, an official enquiry as to the proposal has been held at the Guildhall by Mr. Frederick Herbert Tulloch. M I.C.E., Local Government Board inspector. The town clerk (Mr. S. Southall) represented the City Council, and there were also present Alderman T. Rowley Hill, Mr. G. H. Williamson (chairman of the Electricity Committee), Mr. W. H. Preece (consulting electrical engineer), Mr. F. R. Davenport (Mr. Preece's assistant), Mr. T. Caink (city engineer), Mr. Ruthven Murray (city electrical engineer), and Mr. F. George (city finance clerk). The Town Clerk explained that the Corporation applied for a loan for electric lighting purposes of £39,109 and that was sanctioned on August 5, 1893. That loan was intended to cover three items: purchase of land, £5,000; erection of generating station, £11,000; and generating plant and some mains in the city, £23,109. The City Council afterwards applied for a further loan of £1,861, which was sanctioned on July 2, 1894. That referred to street-lighting. As regarded the first loan, they had expended on the purchase of the land £5,060 instead of £5,000. They had to buy another small piece of land, exactly in front of the works, from Sir Harry Vernon, and another piece of land added to the mill pond, the two additional pieces costing £85. The land tax was redeemed, when practically the land was vacant, at a cost of £118. 11s. 6d. As regarded the generating station, the Council in the first place understood that the building would cost about £10,000, but the contract amounted to £14,797, leaving an excess over the loan of £11,000 applied for of £3.797. In reply to an enquiry from the inspector as to a number of extras in the plant at the generating station, Mr. Preece said they gained experience from other places as the work proceeded, and that accounted for many alterations and additions to the work contracted for. The Inspector enquired as to an item in the loan applied for of £500 for additional works by the Brush Company, and Mr. Preece explained that the items were for electrical instruments, protecting the machinery in accordance with the requirements of the Board of Trade, and other small extra works at the generating station. Mr. Preece stated that the final accounts between the Corporation and the Brush Company were not yet settled. He had examined them all and had certified some of them. The only item in dispute was £600, which would be settled by arbitration. The Inspector then enquired into the details of the expenditure for extensions of mains and other works making up the amount of the loan. The proceedings were formal and there was no opposition.

Hampstead.—The Vestry held a meeting last week at which the Lighting Committee recommended that the necessary mains, etc., be laid for the supply of electric current to private consumers in certain roads at a cost of £2.428. Mr. Thwaites, chairman of the committee, stated that 7,338 incandescent lamps had now been fixed by the Vestry's private customers. The revenue last quarter from this source was £770, an increase of £330 over the previous three months. The recommendation was adopted, as

Digitized by Google

was the proposal that the plan showing an extension of the arc lighting in Finchley-road, from Swiss Cottage to Boundary-road, be adopted, at a cost of £175. It was decided that the plan submitted by the engineer for splitting up the network for electric lighting in the parish be carried out at an estimated cost of £300. The same committee reported that they had informed Mr. Preece, in reply to his letter, that the intention of the Vestry, by the resolution of March 14, was that their own engineer should prepare plans and estimates for, and superintend the carrying out of all extensions of, the electric lighting in the parish, but that in the event of any difficulty occurring they would be glad to have his (Mr. Preece's) opinion and advice, upon such terms as should be mutually agreed upon. Mr. Hall moved that the resignation of Mr. Chattock be accepted, and that he be congratulated upon having received a better appointment. This was carried. A fortnight ago the Vestry resolved that the Willesden District Council should be informed that the estimated cost of laying down the necessary mains, with lamp standards and fittings for 24 arc lamps in the High-road, Kilburn, was £1,460, and that the cost of running these arc lamps at the present cost price would be £41 per lamp per annum; also, that the Willesden District Council should be asked if, in the event of the Vestry agreeing to light the High-road, Kilburn, by electricity, they would be willing to pay half of the said estimated cost, and half the cost for the time being of running the said arc lamps. A reply was now received from the Willesden District Council, intimating that, in view of the large outlay and annual expenditure, the Council could not agree to pay half the present estimated cost of such lighting. A letter was received from the London and Hampstead Battery Company, referring to the proposal of the Vestry to carry their electric lighting mains to Kilburn for the supply of the shops and streets of that portion of the parish, and suggesting that some scheme might be employed for the mutual advantage of the Vestry and the company, the latter being of opinion that there was plenty of work for both to do. They stated that they would be willing to transfer to the Vestry all the work which they held on the north side of Finchley-road if the Vestry would transfer to them that portion of their provisional order which covered the portion of the parish south of that road. The letter was referred to the Lighting Committee.

PROVISIONAL PATENTS, 1895.

April 16.

7584. **Improvements in methods of electric distribution.** John Hall Rider and John Pilling, Corporation Electricity Works, Bolton.

7600. **Improvements in and relating to primary batteries.** Walter Rowbotham, Hymen Levetus, and Sarah Isabelle Levetus, 47, Victoria-street, Birmingham.

7625. **Improvements in electric wire insulators.** Daniel M. Rothenberger, Charles A Inglis, and Edward D. Reilly, 46, Lincoln's-inn-fields, London. (Complete specification.)

7649. **Improvements in and relating to electric arc lamps.** Edward Harold Crosby and Otis Madison Shaw, 11, Southampton-buildings, Chancery-lane, London. (Complete specification.

7657. **Improvements in secondary or storage batteries.** William More McDougall, Henry Burr Adams, and George Putnam Smith, 115, Cannon-street, London. (Complete specification.)

7668. **Improvements in systems of electric distribution.** James Devonshire, 24, Southampton-buildings, Chancery-lane, London. (Edwin W. Rice, United States.) (Complete specification.)

April 17.

7703. **An improved electric bell switch and burglar alarm.** George Frederic Lewis Alexander, 69, Lordship-road, Stoke Newington, London.

7705. **Improvements in the construction of holders for electric glow lamps.** William McKenzie and John Ambrose Fleming, the Electrical Laboratories, University College, Gower-street, London.

7712. **Electric bath metal-heating apparatus for metals and ores.** George Dexter Burton, 52, Chancery-lane, London. (Complete specification.)

7713. **Electric bath metal-heating apparatus.** George Dexter Burton, 52, Chancery-lane, London. (Complete specification.)

7714. **Improvements in connection with incandescent mantles.** William Crookes, 55, Chancery-lane, London.

7735. **An improved electromotor.** Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Antonietta Della Casa, Italy.)

April 18.

7773. **Improvements in or connected with the production of electricity.** Harry Tee, 50, Castle-street, Liverpool.

7782. **Improvements in electric resistances.** Julius Ferdinand Heinrich Voigt and Jacob Adolf Haeffner, 6, Lord-street, Liverpool.

7785. **Improvements in connection with ventilating electric culverts, test-boxes, and other street-boxes.** Thomas Harden, 11, Durham-road, Wimbledon, London.

7788. **Improvements relating to electric arc lamps.** William Reginald Ridings, George Frederick Bull, and Llewellyn Burbank Codd, 124, Chancery-lane, London.

7795. **Improved construction of electrical accumulators.** Vicomte Gaston de Schrynmakers de Dormael, 28, Southampton-buildings, Chancery-lane, London. (Complete specification.)

April 19.

7829. **Improvements in the method of and means for charging electric storage cells.** William Joseph Starkey Barber-Starkey, 70, Market-street, Manchester.

7837. **An improved apparatus for electrically heating liquids.** Paul Stotz and Friedrich Wilhelm Schindler-Jenny, 89, Chancery-lane, London.

7888. **Improvements in electric cells or batteries.** Eugène Etève, 4, South-street, Finsbury, London.

April 20.

7910. **Improvements in and connected with apparatus for lighting up roundabouts and the like by electricity.** Frederick John Borland, 8, Quality-court, Chancery-lane, London.

7930. **Improvements in laying electric conductors underground.** Joseph Alexander Jeckell, 46, Lincoln's-inn-fields, London.

SPECIFICATIONS PUBLISHED.

1891.

9762. **Storage batteries.** Currie. (Second edition.)

1893.

5198. **Electrolytic apparatus.** Hargreaves and Bird. (Second edition.)

1894.

8224. **Electric lighting.** Aldridge.

10172. **Electric rail or tram vehicles.** Hopkinson.

10332. **Arc lamps.** Suter.

10426. **Dynamo-electric machines.** Kingdon.

25289. **Primary battery.** Ludvigsen.

1895.

2918. **Dynamo-electric machines.** Devonshire. (Steinmetz).

4106. **Dynamo-electric generators and motors.** Lones.

4153. **Insulating electric conductors.** Johnson. (Downes.)

NOTES.

Navy Search-Lights.—The search-light has been put into practical use by those vessels of our Navy which have been concerned in the occupation of Corinto, Venezuela.

New Edition.—Messrs. Whittaker and Co., of Paternoster-square, E.C., are about to issue a second and greatly enlarged edition of "First Book of Electricity and Magnetism," by Mr. W. Perren Maycock, M.I.E.E.

Is the Profit too Great?—Some anonymous letters have appeared as to whether it is right that the St. Pancras electric light station should show a profit. The argument is that the consumers, being ratepayers and proprietors of the plant, should get current at cost price.

Private Bill Legislation.—The London County Council Money Bill has passed the Examiners on Standing Orders of the House of Commons. The Bill provides, among other things, for the electric lighting of Victoria-embankment and Waterloo and Westminster Bridges at a cost of £21,000.

Institution of Electrical Engineers.—The next meeting will be held at the rooms of the Society of Arts, John-street, Adelphi, on Thursday, May 9, 1895, at 8 p.m., when a paper will be read "On the Recent Development of the Single-Acting High-Speed Engine for Central-Station Work," by Mr. Mark H. Robinson, member.

Electric Traction in Portugal.—It is announced that the French Thomson-Houston Company have arranged to build an electric tramway at Oporto, its length to be about two miles. The installation will comprise a 150-h.p. steam-engine, a 100-kilowatt dynamo, and three cars, each with two 25-h.p. motors. A number of German firms also tendered for the work.

Personal.—Mr. W. Elsdon-Dew, who has been for two years manager and resident engineer of the Kelvinside Electricity Company's supply station, Glasgow, has been appointed resident electrical engineer to the Transvaal Gold Exploration and Land Company, and leaves immediately to take charge of the electrical plant to be placed at their mines in the Transvaal.

Steam-Engines (Persons in Charge) Bill.—It has been agreed that the committee on this Bill consist of 17 members—viz., Mr. Allan, Mr. Brunner, Mr. Fenwick, Colonel Gourley, Mr. Hardy, Mr. Heath, Sir A. Hickman, Sir E. Hill, Sir B. Hingley, Sir J. Joicey, Sir S. King, Mr. Wilson Lloyd, Mr. Paulton, Mr. Renshaw, Mr. John Wilson (Durham), Mr. Woods, and Mr. Wrightson.

American Institute of Electrical Engineers.—We have received the April issue of the *Transactions* of this institute, containing, among other matter, the papers read by Messrs. E. P. Houston and A. E. Kennelly on "Resonance in Alternating-Current Lines," and by Prof. W. A. Anthony on "Underwriters' Rules." An obituary notice and portrait are given of the late Mr. George M. Phelps, the treasurer of the institute.

Foremen Engineers and Draughtsmen. — The members of the London Association of Foremen Engineers and Draughtsmen held their annual dinner at the Cannon-street Hotel on Saturday evening, the chair being occupied by Dr. Anderson, Director-General of Ordnance Factories. Among the toasts was that of "The Engineering Employers," proposed by Mr. W. T. Coates, and acknowledged by Mr. A. Siemens and Mr. Liddell Simpson.

Sanitary Inspectors' Association.—The following are the arrangements of this association for May: May 3—Sanitary Inspectors' Association deputation to Local Government Board on examination question; May 4—paper by Mr. J. Young on "The Dwelling-house from a Sanitary Point of View," Carpenters' Hall; May 51, June 1—visit of the association to Worthing on the invitation of Mayor and Corporation.

"Electrocution."—Dr. J. Mount Bleyer, who has been experimenting in connection with what he styles "acts of electrification," more generally known by the badly-constructed name of "electrocution," has come to the conclusion that death is due to "dynamic apoplexy." This is based on examinations of animals which have been killed by electricity, and also on the results of a post-mortem of a criminal who was this year executed at Sing-Sing.

Electric Lighting in France.—The Edison Company, which supplied current to portions of Lille, have passed over their contracts with their customers to the local Société d'Eclairage Electrique.—The Compagnie Electrique du Secteur Gauche, Paris, have received authority for an extension of their mains.—The Compagnie Electrique de la Banlieue-Ouest, of Paris, have been granted the monopoly for the electric lighting of the town of St. Cloud.

Electric Target.—The *Oesterreichische Militär Zeitung* states that experiments have been conducted at the military ranges at Graz, Austria, with an electric indicating target which has been invented by Colonel Felix Mauthner, of the 47th Infantry Regiment, and Mr. Fritz Figlovsky, an engineer. It dispenses with the services of markers, the target upon being struck showing approximately the part which has been hit both by signal and by means of a visible indicator.

Institution of Engineers and Shipbuilders in Scotland.—The annual general meeting of the thirty-eighth session of this institution was held in Glasgow last week, when the treasurer's annual financial statement was submitted and the award of medals and premiums for papers read in session 1893-94 made. A discussion also took place on a paper by Mr. W. Carlile Wallace, entitled "Electrical Transmission of Power in Shipyards and on Board Merchant Steamers."

Temperature of Incandescent Filaments.—Prof. Weber has lately given the results of a number of experiments made by him to determine the temperatures of filaments in electric incandescent lamps. He has found that the normal temperatures of all species of incandescent lamps is approximately the same, and is comprised between 1,565deg. and 1,588deg. C. In the case of some lamps giving a very brilliant light—that is to say, with very thick filaments—the temperature is 40deg. higher.

Rail Bonding.—Mr. George P. Low, in the *Transactions* of the American Institute of Electrical Engineers, concludes that the art of rail bonding now appears to have been perfected, and the damage that has been caused by corrosive electrolysis may be attributed to defective bonding, for without doubt proper main-to-track, rail-to-rail, and track-to-dynamo bonding will cure the ill almost without exception. The problem of eliminating electrolytic corrosion is, in brief, simply one of judicious bonding.

"The New Street Danger."—This is a stereotyped heading which the *Lancet* has adopted, that medical organ having of late made a sort of hobby of dealing with Major Cardew's reports, which can hardly be expected to be interesting to a physician as such. The latest conclusion which our contemporary has arrived at is that the gas companies (as well as the electric light companies) should take precautionary measures. The electric light companies are doing so, but the gas companies do not trouble themselves much. Neither are they likely to do so, unless obliged.

Digitized by Google

Society of Arts.—The arrangements for next week are as follow: May 6, at 8 p.m., Cantor lectures, "Recent American Methods and Appliances Employed in the Metallurgy of Copper, Lead, Gold, and Silver," by Mr. James Douglas—Lecture III., "The Metallurgy of Copper"; May 7, at 4 p.m., Applied Art Section, "Recent Improvements in Designing, Colouring, and the Manufacture of British Silks," by Mr. Thomas Wardle; and May 8, at 8 p.m., twentieth ordinary meeting, "The Extraction of the Rarer Metals from their Oxides," by Prof. William Chandler Roberts-Austen, C.B., F.R.S.

Visits to Electric Light Stations.—The Home Counties District meeting of the Incorporated Society of Municipal and County Engineers will be held at Brighton to-morrow (Saturday), when among the visits to be made will be one to the central electric light station in North-road, and Mr. Arthur Wright, the electrical engineer and manager of the Corporation station, will read a paper on "Points of Interest in the Development of Electricity Supply at Brighton." The South Wales District meeting of the association will be held at Cardiff on Saturday, May 11, when the Cardiff electric light station will be visited among other works.

Electric Lighting Plant.—We have received from Mr. Charles A. Müller, 6, Mornington-villas, Bradford, an album of the central stations which have been fitted up by Messrs. Schuckert and Co., of Nuremberg. It is admirably got up. Brief particulars are given of the stations, together with photo-lithographic illustrations. The stations dealt with comprise Lübeck, Barmen, Hamburg, Bergzabern, Hanover, Düsseldorf, Berchtesgaden, Wachenheim, Altona, Christiania, Neuhaldensleben, Penzig, Aix-la-Chapelle, Budapest, Sigmaringen, Haardt, Munich, Zwickau, Steyr, Baden (Vienna), Pforzheim, Salzungen, Donaueschingen, and Copitz, and electric tramways at Zwickau and Baden (Vienna).

Curious Wiring Arrangements.—Mr. Thaddeus, the portrait painter, has raised an action against the liquidator of the Liberator Building Society for damages. It was stated that workmen in the employ of defendant spilled water on a floor in Whitehall Court, and that it ran through a hole in the ceiling through which the electric light wires passed and spoiled some drawings under the electrolier. The marvellous assertion was also made that water was found inside the bulb of an incandescent lamp. The case did not turn upon the wiring arrangements, nor, in fact, on anything connected with the electric light, so that the judges had not to deal with the interesting question of the water entering the lamp.

The Carbonelle Microphone.—Mr. J. Banneaux, the head of the Belgian Telegraph Administration, discussing the question of tests carried on recently over one of the Anglo-Belgian cables with the carbonelle microphone, says that it consists chiefly of two carbon discs with carbon granules between them. The characteristic feature of the instrument is its extremely high resistance, amounting to several million ohms. Its resistance varies also within wide limits. A common or centralised source of electrical energy is employed for a large number of transmitters. Mr. Banneaux considers that the tests have not proved the superiority of the carbonelle system over transmitters such as the Hunnings, Grünewald, etc.

Heat-Engines.—Last night (Thursday) Prof. W. C. Unwin delivered at the Institution of Civil Engineers the "James Forrest" lecture, his subject being "The Development of the Experimental Study of Heat-Engines." Among the different points dealt with were tests of steam-engines in Cornwall, experiments on boilers, trials of Welsh and North Country coal, the Mulhouse trials of 1859, the Dasymeter, experiments on steam-engines, Isherwood's experiments on marine engines, the physical properties of steam (Regnault), the foundation of thermodynamics (Carnot and Joule), the founders of the rational theory (Rankine, Clausius, Zeuner), the experimental theory, the conflict of the rational and experimental theories (Zeuner, Hirn, and Hallauer), and recent experiments (Willans).

A 67-Ton Electric Locomotive.—The Baldwin Locomotive Works have completed a 67-ton electric locomotive from designs by Messrs. Sprague, Duncan, and Hutchinson. It is intended for special experimental work in handling heavy freights, and for shunting. The motors, four in number, and alternating in position, are of the "Continental" iron-clad type, the field magnets consisting of two steel castings, having two field coils placed at the ends of the motors, thus forming two consequent and two salient poles. The magnets are compound wound, and the armatures are of the slotted type. The motors are wound for 800 volts at 225 revolutions, which equal about 35 miles an hour when in multiple. About 250 amperes of current will be used, and at 93 per cent. efficiency each motor will give about 250 h.p.

Society of Engineers.—The next ordinary meeting of this society will be held at the Westminster Palace Hotel on Monday at 7.30 p.m. A paper will be read on "Street Subways for Large Towns," by Mr. Charles Mason, A.M.I.C.E., surveyor to the Vestry of St. Martin-in-the-Fields, of which the following is a synopsis: Introduction—Necessity for subways — Present underground arrangements unsatisfactory—Interferences with street surfaces—No recognised system for laying pipes—Acts of Parliament—Companies present powers—By-laws—Companies' objections thereto—Municipalities losing control of the streets — Early subways — London subways — Provincial subways — Difficulties of construction — The author's proposals — Points for consideration in designing a subway—Cost of construction—Revenue—Subways in old streets—Inspection and supervision—Municipal control—Conclusion.

British Patents.—In reply to Mr. A. C. Morton in the House of Commons, Mr. Bryce said that printed weekly and annual indexes of all British patents were regularly supplied to libraries in the cities of London, Manchester, Leeds, Glasgow, and Dublin, and also to 31 other business centres. It was well known that the grant of a patent carried with it no guarantee of validity. Mr. Bryce also said that he was aware that the average lifetime of a patent in this country was about five years. In 1893 and 1894 it was about four years and eight months. The number of patents which lapsed in 1893 was 9,302; and in 1894, 9,925. The Board had no power to instruct members of the profession of patent agents to make any statement on the subject. He believed that, as a rule, inventors were aware that the life of a patent depended on the payment of renewal fees. There was a statement to this effect on every patent issued.

The Proposed Pacific Cable.—The correspondent of the *Times* at Ottawa, telegraphing on May 1, says: "Information received here indicates that there is no possibility of securing a station for the proposed Pacific cable in the Hawaiian Archipelago. The advocates of an entirely British route will not regret this, as they prefer that Fanning Island should be selected. The Imperial Government is being urged to summon a conference of the colonies concerned to arrange the details of the construction of the cable." From Melbourne, on the same date, a *Times* correspondent telegraphed: "Mr. Larke, the delegate of the Canadian Government, has proposed to the Sydney Chamber of Commerce a scheme for the laying of a Pacific cable by Great Britain, Canada, and Australia. The cost would be £1,600,000, which would be borrowed at 2½ per cent.

Digitized by Google

interest. It is estimated that half the present business at 2s. a word would repay the capital in 25 years besides the annual expenses."

Electric Lighting in Germany.—The Allgemeine Elektricitäts-Gesellschaft has been authorised to erect a central station for the supply of current to Magdeburg.—At Aix-la-Chapelle the street electric lighting is to be extended.—The private installation at the central railway station at Nuremberg is to be extended in the course of the summer, and a steam-engine of 120 h.p. will be added, bringing up the total horse-power to 400.—The Carolinenthal Municipality have instructed Mr. Krizik to prepare plans for a municipal central station for the distribution of current both for lighting and power purposes.—The proposal to establish a central station at Schneimühl has been shelved for the present.—In view of the increasing business at Cologne harbour, it has been decided to light the wharves electrically.—At Plauen a central station is to be erected by private enterprise.—An order has been given for a fourth alternating-current steam dynamo of 150 h.p. for the Frankfort-on-the-Maine station, so that by the arrival of winter 3,000 h.p. will be available.

Electrical Resistance.—A paper on the electrical resistance of certain poor conductors, such as wood and stone, by Mr. B. O. Pierce, appears in the *Proceedings* of the American Academy. He has examined numerous kinds of woods and stones under different conditions as to dryness. The author has also tried the effect of soaking the different materials in hot melted paraffin, and finds in every case, especially if the specimen has been previously well dried, that such treatment not only increases the specific resistance, but prevents change of resistance by absorption of moisture. The following are some of the results for the specific resistance obtained in megohms—the first number denotes in each case the lowest value observed, and the second number the mean value: mahogany 310, 610; hard pine 17, 1,050; white pine 360, 1,470; vulcanised fibre 3, 60; slate 184, 280; white marble 2,000, 8,800. The samples of wood were all well seasoned, and the resistance was measured in the direction of the grain, the resistance across the grain being generally from 20 to 50 per cent. higher. The samples of stone were dried in the sun for about three weeks before being tested.

The Pellat Electric Siren.—M. Pellat introduced his electric siren to a recent meeting of the Société de Physique, of Paris. The instrument differs from the siren of Cagniard de la Tour in the two following respects: (1) the holes of the plates have a direction corresponding to the latter; (2) the rotation of the disc is obtained by an electric motor. For this purpose, on the axis of the revolving disc a small Gramme ring is placed within an electromagnet. Current is supplied by three accumulators. No supplementary resistance is introduced into the inductor circuit, but auxiliary resistances are placed in the ring circuit by means of a continuous rheostat. The speed of rotation can therefore be varied at will, and very quickly be brought to a fixed value. Among other advantages, M. Pellat claims for his instrument that it is capable of producing both powerful low and weak sharp notes, which the Cagniard de la Tour siren cannot do; and that the flat sounds are as pure as the sharp, which is not the case with an ordinary siren. When M. Pellat had concluded his demonstration, M. Arnoux remarked that doubtless more fixity in the intensity of the sound would be obtained by the addition on the axis of rotation of a disc of copper revolving in a magnetic field.

A Sensitive Galvanometer.—In the course of researches on magnetism by the ballistic method, M. Pierre Weiss has been led to modify the usual type of Thomson astatic galvanometer, with the view of increasing its sensitiveness and the accuracy of its indications. He has constructed two instruments. In the first the total weight of the movable system is 0·47 gramme; the magnetic circuit is double, and composed of two systems of two magnetised needles 0·6mm. in diameter and 36mm. in length, the axes of which are 2·6mm. apart, fastened upon each of the faces of a thin sheet of mica, which has below the bobbins a concave mirror of 3·75mm. radius and of one square centimetre surface, weighing 0·1 gramme. The bobbins, made of 0·22mm. wire, have a total resistance of 146 ohms; their outside and inside diameters are respectively 27mm. and 9mm. The second galvanometer is smaller than the first in the proportion of 9 to 5 in general dimensions. The two steel needles are 0·2mm. in diameter and 18mm. long, and their distance apart is 1·2mm. The mirror weighs eight milligrammes, and is of rectangular form extended in the direction of the axis, which renders its momentum very small.

Predetermination of the Fall of Tension in Transformers.—A paper with this title has been given by Mr. Gisbert Kapp before the Elektrotechnischer Verein at a Berlin meeting. He stated that the determination of the fall of tension by direct measurements, particularly in the case of large transformers, has its difficulties. In the first place, considerable motive power must be available; secondly, a resistance or other apparatus was required which was capable of taking up a great amount of energy; and, thirdly, it was essential to know the phase-retardation in the secondary-current circuit. If all these conditions were fulfilled, the direct measurement certainly gives the fall of tension for this phase-retardation, but not for other values of the same. Such an experiment, therefore, did not perfectly disclose the behaviour of the transformers in respect of fall of tension. The method which he described and illustrated in detail rendered it possible, on the basis of a very simple experiment which required little motive power, and in which no resistances or energy-absorbing apparatus are necessary, to calculate beforehand the fall of tension for any load and for any positive or negative phase-retardation. Herr Dolivo-Dobrowolsky, in the discussion which followed the reading of the paper, stated that, in his opinion, the method expounded by Mr. Kapp was both very neat and very practical.

Electro-Chemistry.—M. Andréoli takes exception in the *Electricien* (April 20), to some of the statements concerning the electro-chemical industry which M. Lucion made at a recent meeting of the Société des Electriciens Belges. He ridicules that gentleman's assertion that the importance of E.M.F. in electrolysis has been over-rated. He asks if he is certain that the Société Elmore really manufactures 200 tons of tubes weekly. Chlorine does not whiten organic matter, as M. Lucion says anent the Hermite process. Platinum does not resist nascent chlorine, but it is not attacked in a solution of hypochlorite. M. Andréoli is also curious to know where the Knoepfer and Lebauer electrolytic system works satisfactorily, in which a solution of from 5 to 10 per cent. of chloride of sodium is used; and he says there is nothing practical in Lucion's long digression on the ampere-hour, which produces 1·33 gramme of chlorine. Everything depends on the way in which the vat is constructed, the electrodes are disposed, and on the diaphragm. Happy the man who produces one gramme of chlorine in continuous working! The Kelner mercury process, again, has no industrial existence. The Groth electric tanning works at Orbes, in Switzerland, has been abandoned. All, moreover, that Beketoff did, with respect to the electrolysis of

Digitized by Google

chloride of sodium by the dry method, was to read a paper 10 years ago in a technical institute, in which he recounted what he had done with some Bunsen piles as the source of electricity. The refining of lead by the Keith process, M. Andréoli avers, was abandoned a dozen years ago, as has also been the Mœbius process; and the extraction of aluminium by the Montgelas method was never adopted.

Electricity in Agriculture.—Mr. Brettschneider, of Hoppenrade, Mecklenburg, has contributed to the *Landwirthschaftlichen Annalen des Mecklenburgischen Patriotischen Vereins* an account of the electrical installation on his land. The water power of the Nebel is utilised for driving a turbine, a weir having been constructed across the river. The amount of water available varies with the season, and from 16 h.p. to 22 h.p. is obtained from the turbine, which drives a Schuckert dynamo. Current is taken by different overhead conductors to the mansion, farm buildings, stables, barns, and garden for lighting and power purposes from a switchboard in the turbine-house, where there is also a 66-cell battery of accumulators. The accumulators are charged during the daytime. There are 100 incandescent lamps in the house and 92 elsewhere, in addition to two arc lamps. On the farm there are two electromotors of 10 h.p. and 2½ h.p. respectively The smaller motor is fixed, and drives the pumps for supplying water to the cattle, a chaff-cutter, a bandsaw, a lathe, and a grindstone. The larger motor is portable, and can be taken to the various barns as required, a short branch conductor being attached. Mr. Brettschneider calculates that in the year he uses 120,000 lamp-hours, or an equivalent of 12,000 horse-power hours for lighting, and the equivalent of 22,000 horse-power hours for power purposes, making a total of 34,000 horse-power hours. The cost per annum for this, including wages of an attendant, is £300. The cost for lighting is ·17d. per lamp hour. The author goes into details of his expenditure before he laid down the plant, and finds that he has effected a considerable saving by the new method, besides there being many advantages obtained from the use of the electric light and electromotors.

Electric Passenger Launches at Bergen.—The town of Bergen is built on each side of its busy harbour, a deep inlet of the sea, and until last year the inhabitants had no other means of crossing from one side of the port to the other beyond those furnished by ordinary rowing-boats. Then, however, the increasing commerce and population of the town rendered some quicker means of marine locomotion necessary, and eight electric launches were put on the water, by the Bergens Elektriske Faergeselskab, of the following dimensions: length, eight metres; greatest width, two metres; depth, 0·8 metre; displacement, six tons; passenger capacity, 18. In order to avoid turning when leaving the landing-stage the boats are built bow and stern alike, and furnished with two screws and two rudders. The screws are fixed on a common shaft, which is coupled direct to the series motor, which is placed under the floor in the middle of the launch, weighs 6cwt., is of 3 h.p., and is so constructed that the electric insulation cannot be affected by bilge-water. The accumulators are partly under the seats. The plates are those of the Akkumulatorenfabrik Aktiengesellschaft Hagen-i.-W.; they weigh 28cwt., and have an efficiency of 20,000 watt-hours. The average speed, with a consumption of 2,300 watts, is 2·25 metres per second, which is found to be sufficient in view of the crowded state of of the harbour. The bearings of the motor and the shaft are furnished with self-lubricators, so that the one man who attends to the boat may devote his whole attention to driving and steering it. Each boat runs about 40 English miles a day, and has its accumulators charged during the night, when also cleaning and any necessary repairs are effected. The total cost of the undertaking was £4,500—namely, £2,500 for the eight boats, including spare parts, and £2,000 for the charging station, mooring-place, and landing-stages. The service has so far given every satisfaction.

Royal Institution.—The annual meeting of the members of the Royal Institution of Great Britain was held on Wednesday at the house of the institution in Albemarle-street, Sir James Crichton-Browne presiding. The annual report of the committee of visitors for the year 1894, testifying to the continued prosperity and efficient management of the institution, was read and adopted. The real and funded property now amounts to above £102,000, entirely derived from the contributions and donations of the members, and of others appreciating the value of the work of the institution. Sixty-two new members were elected in 1894, and 63 lectures and 19 evening discourses were delivered in 1894. The books and pamphlets presented in 1894 amounted to about 242 volumes, making, with 578 volumes purchased by the managers, a total of 820 volumes added to the library during the year. Thanks were voted to the president, treasurer, and the honorary secretary, to the committees of managers and visitors, and to the professors for their valuable services to the institution during the past year. The following gentlemen were unanimously elected as officers for the ensuing year: president, the Duke of Northumberland, K.G.; treasurer, Sir James Crichton-Browne; secretary, Sir Frederick Bramwell; managers, Sir Frederick Abel, K.C.B., Captain W. de W. Abney, C.B., Lord Amherst, Mr. William Anderson, Sir Benjamin Baker, Messrs. John Birkett, William Crookes, Edward Frankland, Charles Hawksley, John Hopkinson, Alfred Bray Kempe, George Matthey, the Marquis of Salisbury, Messrs. Joseph William Swan, Basil Woodd Smith; visitors: Messrs. John Wolfe Barry, C.B., Charles Edward Beevor, M.D., Arthur Carpmael, Carl Haag, Victor Horsley, Hugh Leonard, Sir Joseph Lister, Bart., M.D., Messrs. Lachlan Mackintosh Rate, Alfred Gordon Salamon, Felix Semon, M.D., Henry Virtue Tebbs, Silvanus P. Thompson, John Westlake, Q.C., his Honour Judge Frederick Meadows White, Q.C., and Sir William H. White, K.C.B.

City and Guilds of London Institute. — The annual general meeting of the City and Guilds of London Institute for the Advancement of Technical Education was held on Monday at Mercers' Hall, Cheapside. Mr. E. L. Beckwith (treasurer) presided, in the absence of the Earl of Selborne, through illness. There were present, among others, Sir Frederick Abel (chairman of the executive committee), Sir Walter S. Prideaux, Alderman Sir Stuart Knill, Sir Owen Roberts, Mr. Ralph C. Palmer, Mr. T. F. Blackwell (Master of the Salters' Company), Prof. W. C. Unwin, F.R.S. (Dean of the Central Technical College), Sir Philip Magnus (superintendent of technological examinations), General J. W. Laurie, Dr. Spence Watson, Mr. J. J. Cooper Wyld, the Master of the Mercers' Company, the Master of the Clothworkers' Company, and Mr. Arthur L. Soper (assistant secretary). The Chairman, in moving the adoption of the report, referred with regret to the absence of Lord Selborne and to the letter which Mr. Watney had read from him. Commenting upon the various sections of the report, particulars of which we gave last week, he said that on the whole very satisfactory progress had been made during the past year. The Corporation and the City companies had again given their aid, and the institute, among other gifts, had received from the Siemens Memorial Fund a sum which would be very acceptable to

Digitized by Google

the recipients of the Siemens medal. They were doing a very useful work in their own colleges and also in connection with other institutes and polytechnics upon whose governing bodies they had representatives. Sir Frederick Abel seconded the motion, and spoke of the value of that department of the work of the institute which gave instruction in the application of science to practical purposes. He also referred to the excellent work done by the technological examinations department. The report was agreed to. Mr. Beckwith and the other officers having been re-elected, the proceedings terminated. At a council meeting which was afterwards held the Earl of Selborne was re-elected chairman for the ensuing year.

Electric Pacemaker.—A novel application of electric power supplied by the San Jose and Santa Clara Railroad Company, U.S.A., is under consideration. The current is to operate an electric tricycle for cutting out the pace on the wheel track. It was exhibited at the cycle show held last month in San Francisco. It is operated by trolley connection, but the trolley is at the side instead of on the top. The conductor will circle the track. The machine will be in charge of a motorman, and can be run up to a speed of a mile a minute. The wheels of the machine are 30in. in diameter. In the patent claim it is set forth that the object of the invention is to provide a mechanism which is especially adapted as a pacemaker to be used in trials of speed for bicycles in connection with a wind break or shield, which will protect the rider from the resistance caused either by the wind blowing directly against him or the current formed by his own rapid speed. The vehicle is three-wheeled, and is provided with a seat from which the operator manipulates the controlling mechanism. From the front part of the frame of the machine trolley poles extend toward the sides, and carry a trolley wheel which engages the conducting wire. To the machine frame is secured the wind shield, which consists of plates of sheet steel meeting in front at an acute angle, and opening out toward the rear so as to encompass the vehicle, and at the same time to provide a space of sufficient width for the protection of the rider from the wind so long as he remains close to the machine. The apparatus is intended to run on any track, and it is retained in its working position by a framework, one side of which is fixed to the vehicle, while the other extends inwardly to a line parallel to the inner kerb of the track, and having journalled upon it vertical guide rollers. These rollers travel on a permanent guide, which is fixed parallel with the kerb in such a manner that when the guide rollers travel upon that guide the vehicle will be constantly retained at an even distance from the inner line or kerb. Should the practicability of the pacemaker be thoroughly demonstrated it will doubtless become an important factor in the lowering of existing bicycle records.

Royal Society's Soiree.—The first conversazione of the season was held on Wednesday at the Royal Society's Rooms, Burlington House, the guests being received by Lord Kelvin, the president. The attendance was large and the exhibits numerous. In a darkened room, Prof. Roberts-Austen showed an electric furnace for dealing with intractable metals, and in his crucible he melted titanium and chromium and boiled away silver in a vapour at a temperature of somewhere about 2,500deg. C. Prof. Ewing showed the magnetic tester for hysteresis which he brought before the Institution of Electrical Engineers the other evening. Dr. Hopkinson gave experiments on the effects of currents in iron on its magnetisation. Mr. Crompton also had exhibits—namely, apparatus for electric cooking and heating. Sir Benjamin Richardson brought a portable electric cabinet for use in hospitals, and Prof. Ayrton an instrument for determining the mechanical equivalent of heat. Specimens of the deposits which have been formed on the electric lighting mains in St. Pancras were exhibited by Major Cardew. Dr. Fleming had an apparatus for indicating the curves of alternating current, and Prof. Forbes was to the fore with a model illustrating the process of signalling by submarine cable. For an arrangement by Mr. L. Pyke, termed the "hydrogen wall," it is claimed that an increased efficiency in the reduction of the highly electro-positive metals is obtained. Among other metallic exhibits by Messrs. Johnson and Matthey, was a specimen of ruthenium melted by electric arc. In Major Holden's optical electric meters the readings of the dials can be magnified to any extent, as in the Thomson galvanometer, with the advantage that all the working parts of the instruments may be of the smallest dimensions, and be worked by the least consumption of energy. Lord Armstrong showed through the lantern the results of some recent experiments on the electric discharge in air, which were extremely curious and interesting. Prof. Ramsay did not omit to deal with argon, nor Prof. Vivian B. Lewes with acetylene. There were also astronomical and biological exhibits.

Secular Variation of the Earth's Magnetism.—In a recent publication by Dr. L. A. Bauer, entitled "Beitraege zur Kenntniss des Wesens der Saecular Variation des Erdmagnetismus" (Inaug. Diss., University of Berlin), some interesting and important contributions to our knowledge of that enigmatical phenomenon of terrestrial magnetism—the secular variation—have been made. The author has constructed the actual curve described in the course of centuries by the north end of a "free magnetic needle" at various stations (24) distributed over the globe. The result has been the establishment of a law governing the direction of the curve, which the author claims is the first law that has been established thus far with regard to the secular variation as applying to the whole earth. This law may be expressed as follows: the north end of a freely suspended magnetic needle, as viewed from the point of suspension of the needle, moves, in consequence of the secular variation of terrestrial magnetism on the entire earth, in the direction of the hands of a watch. With regard to the period, Dr. Bauer believes that it has not yet been proved that the earth actually possesses a common secular variation period. The only way he thinks it possible to deduce a common period is by the supposition that the curve described by the magnetic needle is not a single closed one, but consists of loops. Indications of such loops, he says, make themselves apparent at various stations. A comparison is also drawn between the secular variation and the momentary distribution of terrestrial magnetism. A secular wave is followed around the earth with the aid of the projected curves. It would appear as though a continuation of the secular curve is obtained by going around the earth eastwardly. The fact thus revealed, the author says, would have, as a direct consequence, that if a survey be made along a parallel of latitude in an easterly direction, a similar motion of the magnetic needle would be encountered as in the case of the secular variation. Dr. Bauer has carried out this idea for three epochs—viz., 1780, 1829, and 1885—and along several parallels of latitude. The curves described by the needle are projected and given on a special plate. It has been found that in every case the north end of the needle, as observed from the centre of the needle, moves clockwise. Furthermore, by a comparison of both sets of curves—the secular and the momentary—it would appear as though they are subject to similar laws.

LEICESTER ELECTRICITY WORKS.

(Continued from page 475.)

The opening ceremony of the Leicester Corporation electric lighting works was described in our last issue, where a general description of the system of the supply and of the commercial aspects of the work will be found. The report of the speeches on the last two toasts were unavoidably crowded out.

Leicester Municipal Buildings.

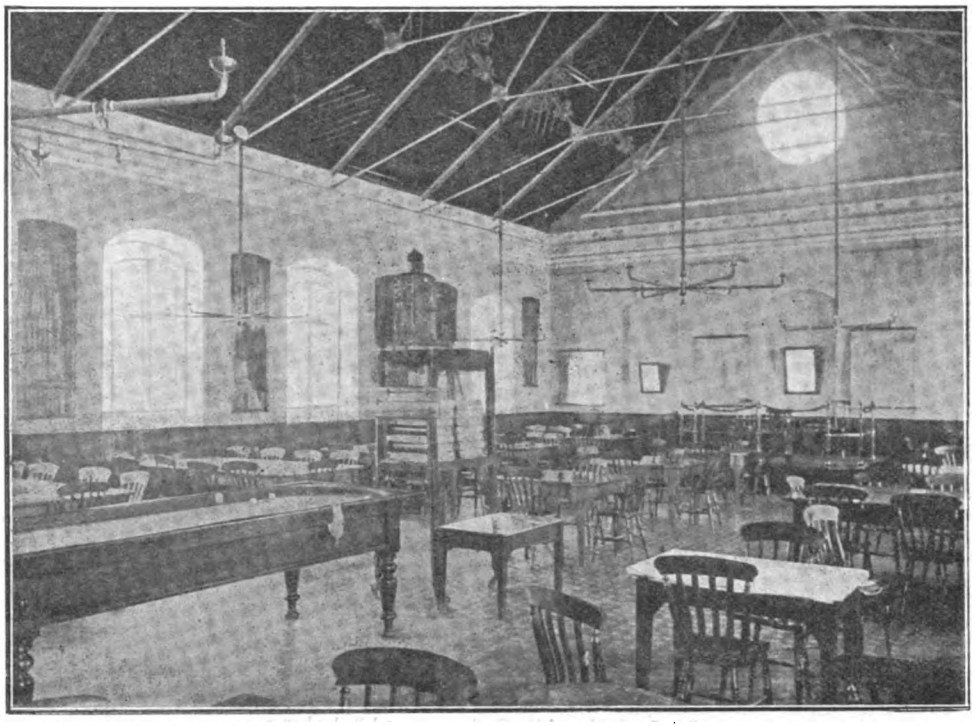
Sir COURTENAY BOYLE, responding to the toast of "Trade and Commerce," remarked that he was immensely touched with the extreme warmth of the reception, and that he should go away from Leicester carrying with him a feeling of gratitude which would last to his dying day. He was especially glad to be present on that occasion, because it devolved upon him in 1889 to advise the Board of Trade with regard to the granting of the provisional order under which the Electric Lighting Committee of Leicester were now acting, and it seemed to him to be very apposite that having taken part in the commencement of the work he should come and see its satisfactory and healthy completion. In some points they were to be especially congratulated in Leicester in the matter of electric lighting. There were no overhead wires in Leicester, and they were spared not only the unsightliness, but the physical and mechanical danger which overhead wires had been proved to create. In the second place, both their gas and their electricity were managed by the same body and the same engineer. It was eminently satisfactory to know that should it be discovered that in one of the transforming-chambers of the town there was a leakage of gas which led possibly to an explosion, it was competent for their engineer, without consulting another department, to go at once and put that right, and prevent a recurrence of that leakage in the future. They had heard a great deal from time to time about the municipalisation of these

ALDERMAN LENNARD,
Chairman of the Leicester Electric Lighting Committee.

ALFRED COLSON, M.I.C.E.,
Borough Gas Engineer, President of the Incorporated Institution of Gas Engineers, Examiner in Gas Manufacture at City and Guilds of London Institute, Designer of the Leicester Electric Light Station.

Digitized by Google

undertakings. All he could say was this, that up to the present such results as those had been achieved by municipal bodies like their own without any impairment of that individual energy upon which their trade and commerce so much depended. He would say that, whatever might be the future of electricity—and he for one most earnestly believed it had an enormous and perfectly unknown future before it—the invention of their scientists, the capacity of those who were already engaged in inventing new outlets for their electrical energy, would not be of much avail unless they were made use of by such municipal energy and enterprise as their committee had shown in this matter.



Library at the Leicester Electric Light and Gas Works in which the luncheon was held.

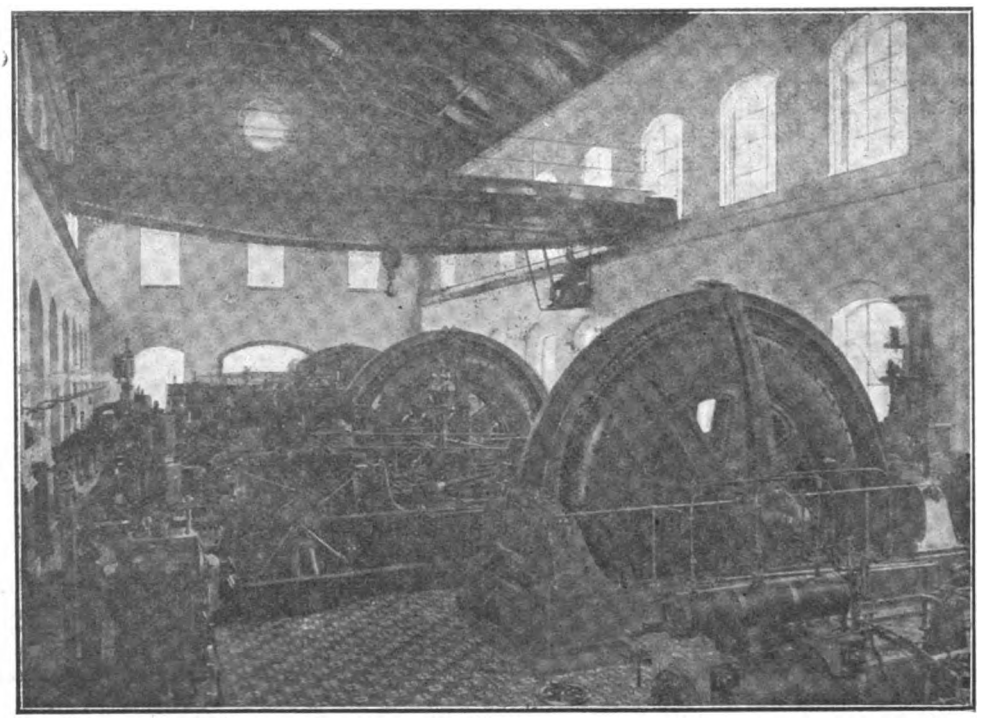


FIG. 6.—View of the Generating Machinery from East Corner of the Engine-room.

In replying to the toast of "The Engineer," Mr. A. COLSON said that it was always encouraging, after carrying out arduous duties, to know that one's efforts met with approval and success. It was more than gratifying to him to hear that the Leicester electric lighting station was, in the opinion of those whose judgment could be relied on, equal to any in this country. Whatever he (Mr. Colson) had done towards bringing about such a result had been done with pleasure, and carried out with an eye to the future requirements. He alluded to the gentlemen who had so ably assisted him in the work, especially mentioning the joint labours of Messrs. Raworth and Mordey. Mr. R. W. Hudson had by his high mechanical attainments fully sustained the high reputation of the firm who made the engines. He also expressed the gratification he felt to the Corporation and the Electric Lighting Committee for the confidence they had placed in him and for the appreciation they showed of the results obtained.

Mr. HUDSON then replied to the toast of "The Contractors," and the company separated after giving a vote of thanks to the chairman.

General Arrangement of Plant.

The ground plan of the electric lighting station was shown in Fig. 3, p. 473, from which the relative positions of the various parts of the generating plant will be readily seen. The 75-kilowatt alternator and engine is placed near the entrance; the other three alternators are each capable of giving 200 kilowatts. Fig. 6 shows a perspective view of the station taken from the corner next to the engineering workshop. From it a good idea of the appearance of the machinery and the general finish of the work is obtained. Fig. 7 is a working drawing of the section of station, and should be looked at by the side of Fig. 3. From these two full particulars can be gathered, and it will be seen that the floor level of the engine works is practically that of the boiler-house. The whole of the steam and exhaust pipes, and the condensing connections, are placed underground in the extensive cellars round the foundations. The ground plan gives some idea of the extent of the accommodation thus provided under the engine-room floor, and in which are conveniently arranged all the wires from the exciters to the alternators, and also the mains from the alternators to the switch pillars. The pipes range along one side of these cellars, and can be approached at nearly all points from wide passages between the foundation. Thus the difficulty and danger, so often found when underground steam-pipes are used, of having to reach a

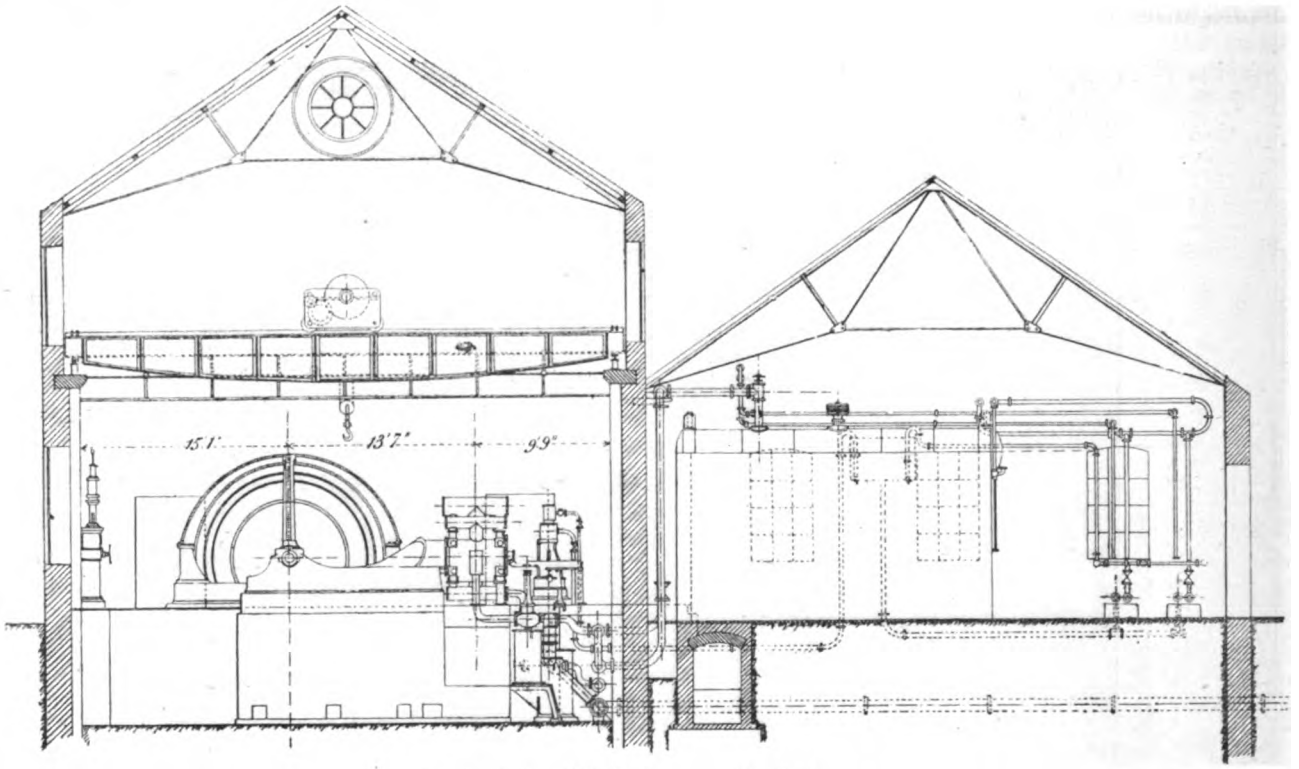

FIG 7.—Section of the Engine-room and Boiler-house.

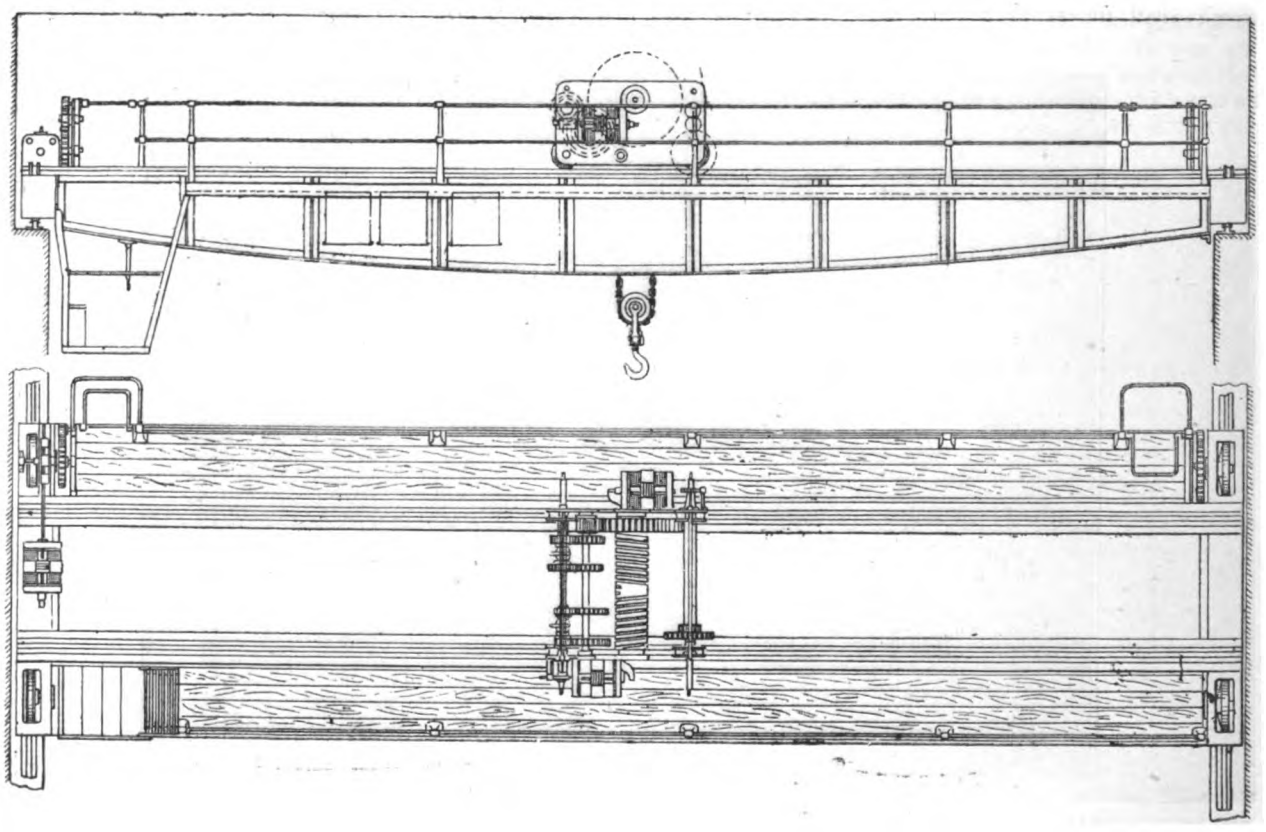

FIG. 8.—Electric Traveller worked by three Brush Motors.

Digitized by Google

leaky joint by walking along the narrow channel containing the pipes, is avoided. Under the floor on the northern side of the building, the cellar spaces are fitted up as oil and general stores. All the foundation bolts run down to the cellar floor line, and are accessible should any need for withdrawing them arise.

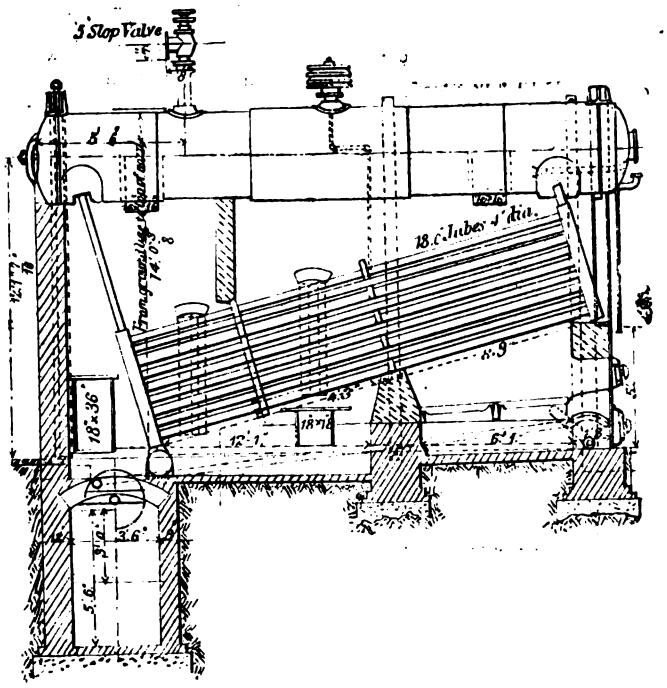

FIG. 9.—Section of the 124-h.p. Babcock-Wilcox Boiler.

A 15-ton electric travelling crane, Fig. 8, runs the full length of the building. Three Brush 4-h.p. series motors are employed to work this crane, one being used for each motion. In this way all transmitting shafts or ropes are replaced by electrical connections. The whole of these motors are controlled, both as to direction of rotation and speed, from a cage below the traveller. From his position the operator commands full view of the whole of the engine-room, and can judge the required movement of the crane with accuracy. The motors transmit their motion to the working parts of the crane by worm gear specially designed by the Brush Company. The worm shaft has roller thrust bearings to reduce friction. The worm is of the best cast steel and gears into a gunmetal worm wheel, the whole gear running in oil. The motor giving the longitudinal motion to the traveller is connected direct to its resistance and switch gear, but the other two—one for lifting and one for the traversing gear—have movable contacts. The current is conveyed to each of these last two motors by collecting brushes, bearing on copper strips running the length of the traveller. Four such strips are used for each motor to enable it to be reversed from the cage. These four copper strips can be seen in Fig. 8, on the inner sides of the two main girders. The motors are direct-current, and are supplied at 50 volts from the exciter sets. The regulating resistances are supported on frames on the underside of the travellers; the regulating switches are so interlocked with the reversing switches that the connections can only be reversed when the regulating switch is in the off position. The omnibus bar supplying the motors is supported on insulators along the length of the engine-house, and a brush fixed on the traveller collects the current as the traveller moves. The return is effected through the wheels to the traveller rails.

Steam-Generating Plant.

The boiler-house is placed behind the engine-room, and arranged to take one more set of boilers when the demand for steam increases. The station is designed with a view to extensions, and the next boiler-house would come on the other side of the chimney, the engine-room being also extended in the same direction. Four boilers of the Babcock-Wilcox water-tube type are at present fixed in the boiler-house in two sets, as is the usual practice of that firm. Each boiler is of 124 actual horse-power, and is composed of seven sections each containing nine 4in. tubes 18ft. long, and has a heating surface of 1,426 square feet, with a grate area of 26½ square feet. The steam-drums are 3ft. 6in. and 23ft. 6in. long, and were tested to a pressure of 225lb. per square inch, the working pressure being 120lb. The boilers have all the usual mountings, the safety-valves being of the Turnbull dead-weight type, and the water-gauges of Dewrance's make. Coke is used in these boilers, owing to the cheapness of this fuel in the gasworks. Fig. 9 shows a section of this boiler and the dimensions of the underground flues as used at Leicester.

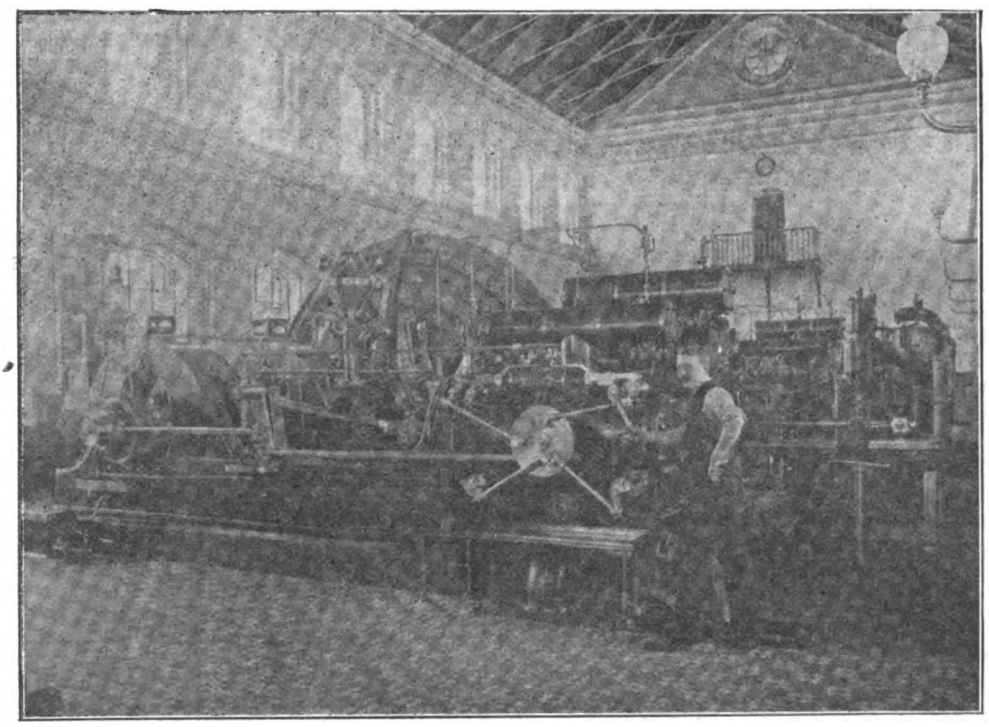

FIG. 10.—200 K.W. Steam Alternator

Feed Arrangements.

The feed water for the boilers is supplied from a large wrought-iron tank, holding 600 gallons, into which the exhaust steam from the exciter and feed-pump engines is delivered, thus heating the water before it passes through the economisers to the boiler. The economiser is of the

Digitized by Google

Babcock-Wilcox type, and has 2,600 square feet heating surface. It is composed of 16 sections, each of 12 3in. tubes 16ft long. The position and arrangement of this apparatus is shown in general plan, Fig. 3.

Two three-throw vertical feed-pumps are installed. These were manufactured by the Brush Company, and are each coupled direct, on one bed-plate, to a Brush 4in. by 4in. vertical steam-engine. Each pump is capable of supplying the necessary feed water when the whole of the generating plant is running, and the connections are such that a direct cold feed can be supplied if needed. The feed-water pipes are of galvanised iron, 3in. in diameter, arranged in duplicate, with valves at suitable intervals, to allow of repairs without interrupting the supply, as will be seen on the plan.

Steam and Exhaust Pipes.

The main steam-pipe is of wrought iron, 6in. in diameter, and arranged as shown in the general plan and elevation (Fig. 3). Valves of the straight-through parallel type are used at frequent intervals, so that any section may be isolated for repairs. The exhaust-pipe is of cast iron, as are also the injection-water and air-pump discharge pipes, and range from 12in. in diameter downwards. The condensing water is obtained from the canal running through the gasworks. The steam-pipes are lagged with magnesia sectional covering, and Geipel's patent steam-traps are used to drain off the condensed water.

The Engines.

The engines used to drive the flywheel-alternators were made by Messrs. Hick, Hargreaves, and Co., of Bolton, and are of the horizontal type with Corliss valve gear. There are, in all, four pairs of compound engines—three of 300 b.h.p. and one smaller pair of 112 b.h.p. The larger engines, Fig. 10, have cylinders 16in. and 30in. in diameter and 3ft. stroke. These are coupled by means of a Raworth coupling direct to Brush alternators, which they drive at a speed of 96 revolutions per minute. Both cylinders are fitted with Corliss valve gearing, and are thoroughly steam-jacketed. The cylinders are built up of separate castings, which consist of four pieces—namely, a liner, a casing, and two end valve-chambers. The advantages of this system of construction are obvious, as it means the substitution of four simple castings, which can each be cast of a mixture most suited to its special purpose. A single casting is of so complicated a nature that it can only be cast of a comparatively soft mixture, and it is even then liable to fail from initial stress aided by unequal expansion.

The system of steam-jackets used in these engines deserves special notice. The steam passes completely round the jackets on its way to the cylinders. This method of jacketing is almost universal on the Continent, and is largely used in America, the lowest steam consumption ever recorded having been obtained from engines jacketed on this system. Messrs. Hick-Hargreaves adopted this system some time back after careful consideration, and are well satisfied with the results since obtained. Its advantages are obvious. There is no possibility of any accumulation of air or water in the jackets, the volume of steam passing through them being so great as to sweep away and prevent the formation of any accumulation of air or water. It also renders it impossible to heat the jackets without heating the cylinders, and the great strains due to unequal expansion and contraction are thus avoided. The efficiency of the jackets as a heating medium is also greatly increased owing to the comparatively high speed with which the steam passes over the surface to be heated. There is a steam-jacketed receiver between the high and low pressure cylinders, in the jacket of which the full boiler pressure is always present. The low-pressure cylinder has the same system of jackets, and the steam from this receiver passes completely round the cylinder before reaching the admission ports.

The main frame of the engine is of the box form, and is made very deep in order to form efficient crank race oil-drippers. The cylinders are attached to the end of the bed-plates by means of hood-pieces, sometimes called target ends. The valve gear differs from that of the usual type, having been designed especially to meet the demands for dealing with the great and rapid variations of load peculiar to electric lighting, with a minimum variation of speed. The gear, which can be seen in Fig. 10, gives very good and rapid port openings and a great range of cut-off—*i.e.*, from nothing up to three-quarter stroke. The governor controls the cut-off in both high and low pressure cylinders, a system believed by the makers to be essential when dealing with great variations in load. The piston rods, cross-heads, crankshafts, and valve-gearing are of steel. The governor is of the high-speed pattern modified Proëll type, with a heavy centre weight on the spindle. Means are provided for altering the speed of the engines slightly for synchronising purposes, and there is a safety stop motion fitted to the governor, which stops the engine at once in case the belts driving the governor break and the latter falls to the bottom, or if from any cause the engines should get so much overspeed that the governor rises to the top of its range. The crankshaft is of the double-throw type, made in two pieces, bolted together with solid flanged couplings forged on the shaft, the flanges of the coupling forming the seat on which the belt pulley driving the governor is fixed.

The air-pump and condenser stand behind the low-pressure cylinder, the latter being of the jet type. The air-pump itself is of the vertical single-acting description, and is driven by means of wrought-iron lever links from the tail end of the low-pressure cylinder piston rod, which is prolonged for this purpose.

The smaller 112-b.h.p. engine is of general construction, similar to that described above, except that on the low-pressure side a slide-valve is used instead of the Corliss gear. The cylinders of this engine are 11in. and 20in. in diameter respectively, and 2ft. stroke. Running at 118 revolutions per minute, they develop some 112 b.h.h.p.

The finish of the whole of the parts has been most carefully attended to by Mr. Colson's special request, and the general appearance of the engines is most pleasing. Well-polished brass oil-catchers are placed under the Corliss gear, and the steam-pipe connections have metallic coverings over the lagging.

The work of erecting these engines at Leicester was carried out by Mr. W. E. Barton, who has since joined the staff of the Corporation.

(To be continued.)

ALTERNATING AND INTERRUPTED ELECTRIC CURRENTS.*

BY PROF. GEORGE FORBES, M.A., F.R.S., M.I.C.E.

(Continued from page 477.)

I will not delay you with these any longer; a series of beautiful experiments may be done with them. I will show you another example, where the ordinary intelligent man with a mechanical knowledge does not immediately realise what is going to happen when a certain experiment is going to be performed. I have a disc of ordinary cartridge paper loaded at the circumference by means of weights, and I shall give a considerable speed of rotation to the disc; and I shall bend this disc while it is in rotation, and I do not think that the result will be exactly as everyone would have expected, Fig. 3. Now we leave it alone, and I do not think that everybody here would have expected it would retain the same shape continuously for so long a time. I go faster, and you see that there is a force which is tending to lead it back to the vertical. In time it would come back to the vertical position.

These are all phenomena dependent upon momentum, and a great number of those in the electrical experiments which I wish to show you are equally dependent upon what is called electrical momentum. Electrical momentum usually goes by the name of "self-induction," and I shall have frequent occasion to use it; and as you have seen the effect in these cases, you will remember momentum is the analogue of self-induction. These experiments also involved a certain pliability (*e.g.*, of the chains), flexibility, ability to move, and a natural tendency to return if not affected by other causes.

Many of the electrical experiments I shall have to show you depend for their action upon electrical flexibility or yielding, which usually goes by the name of electrical capacity. These two things, capacity and self-induction, are the two most interest-

* Lecture delivered before the Royal Institution.

Digitized by Google

ing things which come into the course of these lectures. I shall have to deal with them pretty largely.

Now, I had hoped to have begun this course of lectures with a very striking experiment which I thought was particularly appropriate because it was due to Faraday, and was performed here by him long ago. He discharged a large number of Leyden jars, and tried to discharge them through a lengthy wire; but the discharge preferred to cross from one end of the wire to the other end instead of going round the circuit, although

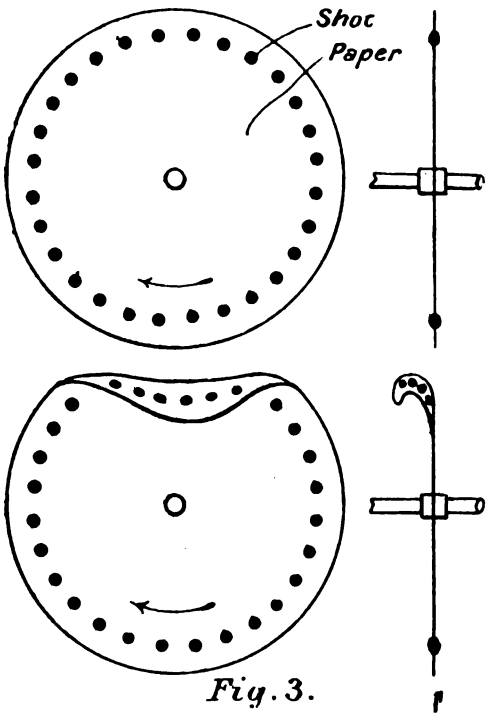

Fig. 3.

that metallic conducting circuit was there, and you would have thought it would go round it. Having, unfortunately, relied upon one who I thought was certain not to fail me, but who has failed me, I have had to abandon the experiment. I would have liked to show it because in that experiment is involved nearly the whole of the principles of the various things I wish to bring before you in the course of these lectures. Instead of bringing all things grouped together in one experiment, and then separating them out, we shall have to proceed to take them separately.

Now, I wish to show you before we go on what is the mechanical analogue which I wish in these lectures to follow up in the study of electric current. The water analogy which I have spoken of is very useful, but I am anxious to draw your attention to the other mode of expressing it, and I will just do so by means of a model here. I have an electric circuit here, and this is an analogy of it.

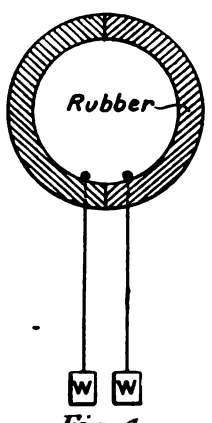

Fig. 4.

There is a central station at the top and there is a power-house at the bottom where the power is going to be used. These are represented on the vertical ring I hold. I have to apply an E.M.F. The energy is purely a mechanical force—a twisting force. I then give a certain twist. By applying the force up here I apply a certain twist to the indiarubber tube, and this force lifts the weight at the bottom, Fig. 4. That is a very simple thing, and therefore it is all the better for illustrating what I wish to say. We may have a continuous current, in which I always wind it up in the same direction, or we may have an alternating current, in which I twist it in opposite directions. The resistance in this case is entirely due to the distortion of this indiarubber, but any other form of friction would do just as well. For example, if I take one of these strips of telegraphic paper and twist it round at the top, there is a certain amount of air friction resisting the twisting; or I might suspend in water or oil anything I wish to twist, and that would illustrate it in the same way.

Now, the first thing I wish to give a little idea about capacity. Of course, as I mentioned, an Atlantic cable has certain amount of capacity, a considerable capacity, and it shows itself by a charge upon the outside of the cable. To illustrate this more clearly, I will just go through the experiment of charging a Leyden jar and then discharging it, just to show you what I mean by capacity and what I mean by something which will hold a charge. [*Experiment.*] Now, an Atlantic cable consists of a wire surrounded by insulating material. The wire is the one conductor—we will call it the internal coat—and the sea is the outer one, and this is to be charged to a certain potential or pressure which you are using. Now, to charge any portion of it, that involves the passage of a certain quantity of electricity through the cable. But the current cannot pass instantaneously through the whole length of the wire because the condenser action is demanding a certain supply for every section of cable as you go from one side of the Atlantic to the other, and the resistance of the wire will not allow it to flow more rapidly than at a certain rate with the number of batteries you happen to be using. That is the foundation of the difficulty that arises in dealing with submarine cables.

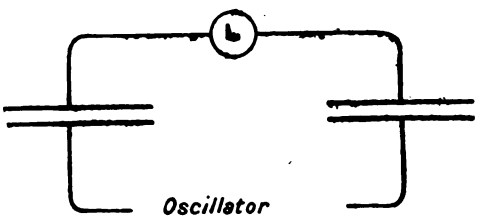

Fig. 5.

Now, I wish to illustrate this question of capacity to make it a little more clear, and will do so at the risk, perhaps, of confusing you a little; but I will try to avoid that. I have here an arrangement by means of which I can charge and discharge a condenser with extreme rapidity. The amount of electricity which a Leyden jar can hold is extremely small. Faraday used to say that in decomposing a drop of rain there is far more electricity used than there is in a lightning flash. The little Leyden jar which I used just now is capable of holding but a very small quantity of electricity, and the condenser which I am going to make use of immediately is capable of holding still less, and holds very little electricity indeed. But by using a current interrupted with extreme rapidity, and reversing it, I am able to supply the current at very rapid intervals, so that the total quantity which passes in one discharge is very small, but the total quantity which passes in the course of a second is very large indeed owing to the enormous number of discharges which take place in the course of a second. I am going to show you

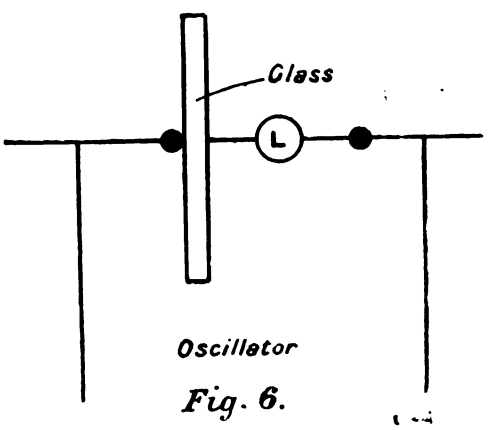

Fig. 6.

that by using two pairs of tin plates we have two condensers of far less capacity than that of the Leyden jar which you saw just now, and yet their capacity will be sufficient with the enormously high pressure I am going to use and the very rapid alternations to provide a current sufficient to light an incandescent lamp, which is really a considerable quantity indeed. I now take the two top plates of the condenser and place them over the others, and you see a light glowing. I can place them still lower, and you get a brilliant illumination passing through that extremely simple capacity, simply owing to the hundreds and thousands of volts we are using and the enormous frequency of alternations, Fig. 5.

Digitized by Google

Now, while I have this apparatus I will show you the effect in a more exaggerated manner. I am going to use simply two points separated by a glass plate. The capacity of this arrangement is something almost infinitesimal, and yet by using these enormous electric pressures and the high frequency which we are employing, we are able to get light enough to light a lamp. I lean a glass plate against one of the terminals, and to the other terminal I attach an incandescent lamp with a wire leading up to the glass plate. Now, the capacity of that jar is really almost infinitesimal, and yet there is a sensible amount of electricity passing into and out of it during the time I am exhibiting it, Fig. 6. This is a very striking experiment, and as I have got this here I will show you what the capacity of my own body is. I think you may take it that this ground is completely insulated, and that there is no current capable of going through me to the ground. Therefore, since the lamp is only attached to one of the terminals, the current has no complete circuit to pass round, and when I touch this it is only by charging my body and then discharging my body that the lamp is able to lighten up, Fig. 7. There is the lamp lighted and sending a current through my body, and utterly imperceptible to myself.

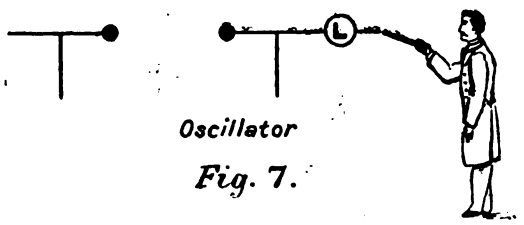

Fig. 7.

Now, capacity is what I am going to deal with chiefly to-day, and most of the rest of my lecture will be devoted to illustrating the Atlantic cable. But I will first show you the kinds of models that I have found instructive, and they are of the rudest and most elementary characters; and as soon as you realise what you can do by thinking over these simple models, and the perfect analogies you can get to the electrical phenomena, I am sure it will be a very great help to you in working out any electrical problems or in thinking what is going on in any electrical problem.

Well, in the first place, I am dealing altogether with twisting of wires. I consider that the E.M.F. is the force with which I twist it. I can measure the force with which I twist anything by winding a wire round it and letting it go over a pulley and putting a weight on it, Figs. 8, 9, 10, and 11. That force is the E.M.F. Here I have a central station with a twisting force, here I have the line going to a distant place, and there I have a resistance, and a resistance eventually such as to equalise the force I am exerting. There is also a definite velocity of rotation attending, which is analogous to the current. Therefore in these models twisting force is the E.M.F., friction is resistance, and velocity of rotation is electric current. In such a station I can have either a continuous current, ever going round in the same direction, or I can have an alternating current, going first in one direction and then in another. In each case, if the wire is perfectly stiff, it is pretty easy to follow the phenomena which are going on.

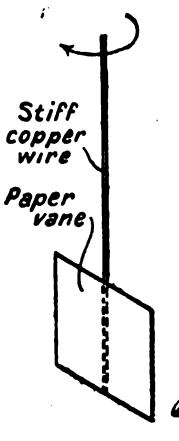

Fig. 8.

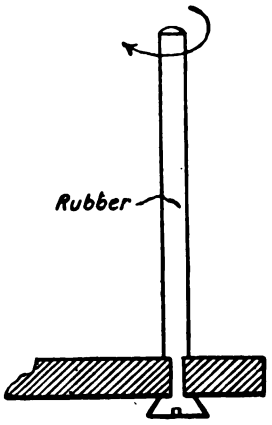

Fig. 9.

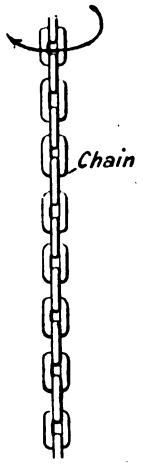

Fig. 10.

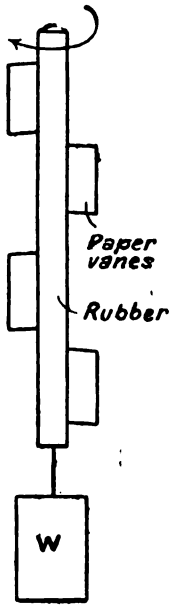

Fig. 11.

Now, I have a number of other cases. You may take any mechanical devices for these illustrations, and you can find electrical analogues. Here is a case. Suppose I twist that elastic string at the top and keep it fixed at the bottom—what is that equivalent to? It is equivalent to a cable of large capacity which is insulated from the earth, and not free. In that case there is a certain charge given to it with any E.M.F.; in other words, there is a certain twisting given to it, with an ounce weight, for example. Therefore we are able to conceive of capacity as a yielding in the same direction, and the charge is the amount of that yielding. A twisting, flexible thing like this is a charged cable. I have here something which represents a combination of flexibility in the cable, which is the capacity of momentum at the far end, which is self-induction, and of air friction, which is resistance; and if I pass alternating currents through that, you will notice that the progress is in a sort of wavy motion down the length of the line. Exactly the same thing happens in the electrical case, provided you have your units in the two cases proportionate to each other. Here I have a heavy chain. When I twist this chain round backwards and forwards it does not all rotate at the same time; that is due partly to its having pliability, which is capacity, and also weight, which is momentum. The weight prevents the motion being communicated to the whole length at the same time.

And now I wish to draw your attention to submarine cables. Before going on to the analogies in that, I will simply show you how a trough of water is an analogy of a submarine cable. This trough has capacity at every part of it, because the level can rise; thus in every way the propagation of a wave along the trough is analogous to the propagation of a wave in a submarine cable—in fact, it is a very accurate analogy indeed. To illustrate it, I will simply make a few waves, and you will see the propagation of the waves along the whole length of the level surface, the change of level taking some time to reach the far end, Fig. 12. That is what happens in the case of a submarine cable—it takes some time to reach the far end.

I wish now to show you a most curious thing. I have here a string suspended from a spring with a set of vanes and two nozzles for blowing against the vanes; there is also a thread coming down through the glycerine and water in the tube, and at the bottom I have a mirror, from which I can reflect a beam of light. The mirror might be attached to the bottom by a spring, but instead of having a spring I have an obvious method of attaching a small magnet to the bottom, and using controlling magnets. Let me refer you to this diagram. The spring acts as a condenser, and the air-blast and the vanes take the place of the battery. The spring below takes the place of the condenser. That is an ordinary way of sending messages through an Atlantic cable. But before doing this I wish to show you the phenomenon of the retardation of the current in an Atlantic cable—that is to say, by means of those artificial cables which are made by Dr. Muirhead, who has assisted me so much. Dr. Muirhead's artificial cables are made of tinfoil, cut in that shape so as to have high resistance. Opposite to it is placed another perfectly flat, which is connected with the earth, which acts as the sea. They are separated by paraffin. He builds up his cable that way, and thus makes an Atlantic cable. Now, to show the retardation of phase. This galvanometer is connected with the sending end; the current will then pass through the whole length of the cable and come out at the other end, and, passing through the galvanometer, there deflect it. The movements of these galvanometers will be seen by spots of light shining on the screen. Now, Mr. Edgar is going to send a signal through the cable, and what you will have to observe is that the sending galvanometer is deflected immediately, and the other takes a long time before it is affected. [*Experiment.*] You can see the interval

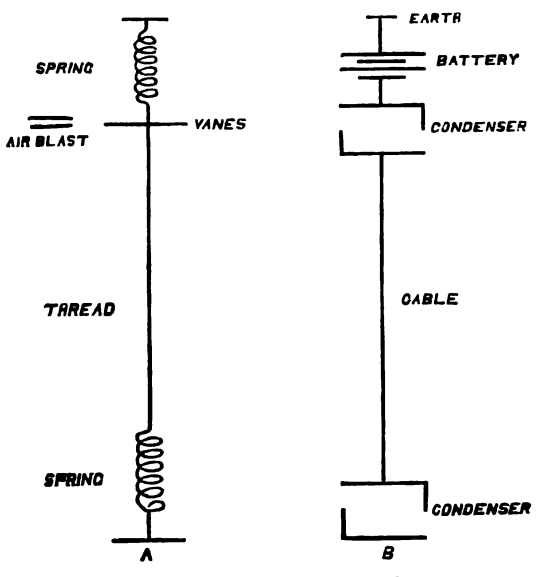

FIG. 12.—A B represent Earth.

Digitized by Google

of time between the sending signal and the arriving signal, and you also see how gradually the arriving signal creeps up. Exactly the same is noticed when I rotate the vanes at the top of the thread hanging in the tube of glycerine that I have just described to you, and the deflection of the mirror at the bottom is noted. This, I have to say, is really, if you choose your units, a perfect representation of the Atlantic cable. I would like to devote a little more time to show how by measuring the twist you can get the capacity and the resistance. Time will not permit me to do that, but I may perhaps have more to say about that on another occasion.

I will now show you some further illustrations of this. I will begin with using the suspended thread in order that we may see and calculate beforehand what we ought to expect from the cable. We will use the suspended thread first without a curb. Let me tell you what a curb is. In the Atlantic cable it is found that if you simply send a positive current through, the signal arrives in a certain manner which would be perfectly satisfactory, but it is much improved if, after having given a positive current, you give it a short time afterwards a negative current. I will put it in another way. If you take a whip with a long lash, and you want to make a crack you may give a forward motion to the lash, and you get a certain amount of cracking; but you get a much sharper crack if you follow it with a backward motion. So here, curbing with my cable means giving it first a twist in one direction and then a twist in the other. Not curbing simply means giving a twist in one direction only. We will signal the letter S—that means three dots—to show you what does take place in a real cable. You will follow it by means of the spot of light you see on the screen. I want to show you the difference between curbing and not curbing. When you are telegraphing quickly, the signals bank up on the top of each other, and cause the spot of light to travel further and further away as the second and third dots come. With curbing this does not occur. Now, by depressing first the positive key and then the negative we can produce the equivalent of curbing, and Mr. Edgar will be able to show you that by means of the reflection on the screen. [*Experiment.*]

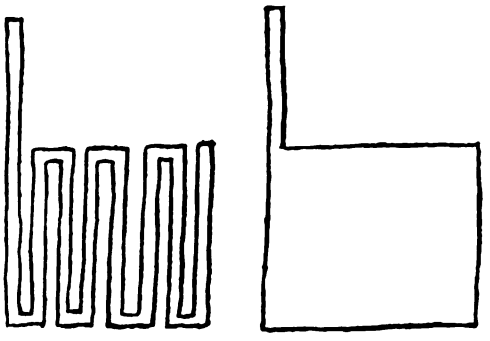

FIG. 13.

In conclusion, I wish to draw your attention to the beautiful apparatus which is used in the operation of transmitting through an Atlantic cable. In the first place, the message is punched out on a piece of paper, and it is punched so as to send the current in either a positive or negative direction. The strip of paper is afterwards passed through the transmitter, and as it is passed through contact is made through the holes, and the message is sent. We will now transmit a message through here. [*Experiment.*] As a matter of fact, the messages which are sent through the cable are received on an instrument called a syphon-recorder, which was originally invented by Lord Kelvin. There is in the curb sender I have on the table a most beautiful device, for while it is working I can, by turning this screw, vary the amount of current that is sent through the cable, and by varying it you are able to adjust the signals so as to get the most beautiful trace of the recorder possible; and also by this means, not using a condenser, but by direct signalling, you are able to get an increase of speed in some cables of about 25 per cent., which is a matter of great importance. I do not think there is time to go into much more, but I am able to show you a few specimens on cards of some signals made in three different ways: first, with a condenser; second, without a condenser; and third, without a condenser and with a curb, and the third is the best. I wanted a word with a good many "h's" in it, and so I selected the name of a member of this institution who has had a great deal to do with telegraphs, and there are the marks exactly as they came out drawn by the recorder itself—Hughes.

Electric Lighting in Spain.—A central station is to be erected shortly at Carthagena, a special feature of which is the fact that two Laval steam turbines, each of 100 h.p., are to be employed.

CITY AND GUILDS OF LONDON INSTITUTE.

ANSWERS TO THE QUESTIONS IN ELECTRIC LIGHTING AND POWER TRANSMISSION.

ORDINARY EXAMINATION, 1894.

(Continued from page 476.)

1. Describe and sketch some form of ampere-meter of a type which does not depend on the magnetisation of iron.

Instruments used for measuring current strength, and which do not depend on the magnetisation of iron, depend on the measurement of the mechanical forces between adjacent coils having current passing through them. Siemens's electro-dynamometer is an example of this class of instrument, and it consists of two coils, one of which is fixed permanently, whilst the other, composed of one or two turns, is suspended by a thread and controlled by a spiral spring. The current passes through the two coils in series, connection being made by means of mercury-cups, so that the movable coil is perfectly free. In the normal position the movable coil is in a plane at right angles to the plane of the fixed one, and when the current circulates through them the movable coil tends to place itself parallel to the fixed one, but this is prevented by turning the torsion index until the torsion of the spring balances the torque.

The mechanical force between two adjacent wires carrying electric current is proportional to the product of the two currents; since in this case, when the same current is passing through both coils, the force is proportional to the square of the current. The force is also directly proportional to the angle of rotation of the torsion spring. Hence the value of the current is given by the formula:

$$C = K\sqrt{\theta};$$

where C = the current in amperes;
K = a constant depending on the construction of the instrument and the spring used;
θ = the angle of torsion required to keep the movable coil at zero.

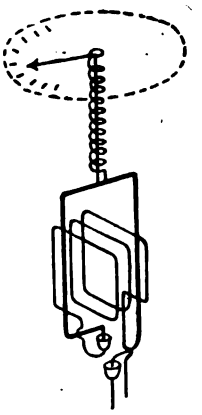

FIG. 1.

Fig. 1 shows a diagrammatic sketch of the instrument.

3. Give sketch to one-fourth full size of a switch for breaking an alternating current of 20 amperes at 2,000 volts.

UNACCOUNTED FOR.

The examination of the Huddersfield accounts for the year ending December 31, 1894, directs our attention to a subject which has often been discussed, but about which there are still great divergencies of opinion. We do not for one moment desire to suggest that Huddersfield is better or worse than other stations, but what we do want to impress upon our readers, and especially upon those connected with municipal supply, is the necessity of careful design and workmanship. Indeed, we think the greatest credit is due to the authorities at Huddersfield and elsewhere who have the courage to give the figures which enable us to get some idea of the losses incurred in central-station work. The aim of a central station is to sell or use all the current generated. Such perfection is, of course, impossible, and the next best thing is to sell the largest percentage possible of the current generated. Take the case of Huddersfield—always remembering that it is taken merely as an example, and for no other purpose—the cost of generating 265,146 units is £2,184. 5s. 5d., which gives a cost of 1·98 pence per unit. But 99,490 of these units are unaccounted for, leaving 165,656 units sold or used. There can be no revenue accruing from units lost, so we ought to take the cost of generation per unit sold, which with the figures given is 3·16 pence. Now, the smaller the losses, the nearer will these two costs approach, and one of the signs of good design and good workmanship is the smallness of the difference. The efficiency of any piece of machinery is recognised, so we may well recognise the efficiency of a combination in which is included management. We incline to the opinion that no station can be recognised as efficient unless the percentage of units sold is over 80. Losses, as we have said, are unavoidable, and 20 per cent. loss would be our limit as allowable, and this only under exceptional circumstances. It may be well to consider for a moment any exceptional circumstances which tend to increase the losses and to lessen the efficiency of the station. In the first place, the station efficiency for a few months more or less after commencing operations must generally be low. If we are dealing with an high-pressure system, transformers are installed, not with a view to the early work, but with a view to the average work; hence considerable losses may arise in the transformers. With regard to this, there comes in the question of design of transformer and its efficiency. If of good design, the losses are reduced to a minimum; if of bad design, the losses may be anything. In his book on "Alternate-Current Transformers," Mr. Weekes, discussing the question, says:

"The importance of reducing the iron loss will be seen when it is remembered that an average private house takes from five to twenty Board of Trade units per year per 8-c.p. lamp installed. If we consider a house having 120 of such lamps fixed, it might safely be supplied by the second transformer on the list. During the year it might take and pay for 13 units per lamp, or $120 \times 13 = 1{,}560$ units for the whole supply. But the transformer has 14·6 per

Digitized by Google

cent. of iron loss, or wastes 545 watts continuously. Taken over the 8,760 hours in the year, this amounts to $\frac{545 \times 8,760}{1,000}$ units = 4,760 units. That means that four times the quantity paid for has to be generated. The efficiency of distribution is then $\frac{1,560}{6,320}$ = 24·6 per cent., neglecting the loss in the line. Now, if the iron loss were reduced to 2 per cent., which may be reasonably expected, the annual waste in the iron is then $\frac{75 \times 8,760}{1,000}$ = 655 units; so that, neglecting copper loss, the efficiency of distribution rises to 70 per cent. With other consumers, such as clubs and shopkeepers, the efficiency will be considerably over 90 per cent. if the load is steady for any length of time. The copper loss is important at full load, but decreases as the square of the current used, and so may be neglected at light loads. Thus, if the copper loss is 2 per cent. at full load it falls to ·5 per cent. at half load, ·125 per cent. at one-quarter full load, and to ·02 per cent. at one-tenth of full load. Hence, the regulation required does more to determine the copper loss allowable than the consideration of the actual waste in the copper circuits."

If now we have to deal with a low-pressure system, the principal loss will be in the mains, and this is easily calculable. There are other losses, such as leakage and so on, that might be considered, but these may wait another opportunity, enough having been said to point out the importance of the subject.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

CITY AND GUILDS EXAMINATION.

SIR,—I beg to draw your attention to the answer which appeared in last week's issue of your journal to No. 6 question of the City and Guilds examination paper of 1894. The question is as follows: Current is required along a street 2,000ft. long at the rate of one ampere per 10ft. frontage. Give sectional area of conductor, so that the difference of pressure between *any two lamps* shall not exceed two volts in the following two cases—(*a*) the current being supplied at one end, (*b*) the current being supplied midway.

You will notice that I have italicised the words "any two lamps." I have done this, as I think you have overlooked them. In your answer you have taken the fall of potential between *each two* lamps to be two volts, and therefore the fall of potential for the whole 2,000ft. is equal to 400 volts. I feel sure that no examiner would set such an impracticable question as that. If you take the fall of potential between any two lamps—say, the first and last—to be equal to 2 volts, ∴ the resistance of the whole line = ·01 ohm.

$$\therefore \cdot 016 : \cdot 01 : : 1 : x,$$

$$x = \frac{\cdot 01 \times 1}{\cdot 016} = \cdot 625 \text{ square inch,}$$

which I think is the most probable answer. I do not think I need trouble you with corrections for (*b*), as, of course, they are of the same order.—Yours, etc.,

HENLEY L. HOWARD.

94, Stamford-street, S.E., April 29, 1895.

[We regret the error pointed out by Mr. Howard. Our contributor must have been working at some high frequency experiment when he proposed to light a street a third of a mile long by a No. 15 B.W.G. We would point out to Mr. Howard that he, too, has made a slip, and assumed that only one wire was required. The correct section is 1·25 square inches.—ED. *E. E.*]

WHAT, WHEN, AND WHERE.

Royal Institution, Albemarle-street, Piccadilly, W.

May 7, 3 p.m.—The third and last lecture on "Alternating and Interrupted Currents," by Prof. George Forbes, M.A., F.R.S., M.I.C.E.

Institution of Electrical Engineers.

May 9, 8 p.m.—At the Society of Arts, John-street, Adelphi, "The Recent Development of the Single-Acting High-Speed Engine for Central-Station Work," by Mark H. Robinson.

Iron and Steel Institute.

May 9, 10.30 a.m.—General meeting for presentation of report, etc. The president-elect (Mr. David Dale) will deliver his inaugural address, to be followed by other selected papers.

May 9, 7 p.m.—Annual dinner at the Freemasons' Tavern.

May 10, 10.30 a.m.—The following papers are expected to be read and discussed: 1. "On Metal Mixers as Used at the Works of the North-Eastern Steel Company, Limited," by Arthur Cooper. 2 "On the Hardening of Steel," by H. M. Howe. 3. "On Tests of Cast Iron," by W. J. Keep. 4. THE EFFECTS OF ELECTRIC CURRENTS IN IRON ON ITS MAGNETISM.*

BY DR. J. HOPKINSON, F.R.S., ETC.

Let us recall a well-known experiment of Faraday's. Upon a ring of iron is wound a few turns of copper wire, through which may be passed a current. On it is also wound a second coil, the ends of which are connected to a galvanometer. It was known that when a current is passed through the first-named or primary coil, the ring becomes a magnet, and that if the current is reversed in direction the magnetisation is also reversed. Faraday showed that when the magnetism is reversed, a transient current is caused in the second coil. The current which is reversed is a measure of the magnetising force; the total amount of current caused in the second coil by the reversal is a measure of the induction of the magnet. The current in the second coil is opposed in direction to the current in the primary after reversal—that is, it is in the direction of the current before reversal. If the changes in magnetisation in the iron produce a current in the coil which is connected to the galvanometer, it is clear that they will also tend to produce a current in the coil which in like manner surrounds the magnet, and which has been connected to the battery. This current is what used to be known as the extra current. It continues for a short time the current in the battery coil in the direction which it had before reversal, and retards its change to

* Paper read before the Royal Institution.

Digitized by Google

the opposite direction. If the battery which gives the current is a battery of many cells, and its extra E.M.F. is taken up by ordinary non-inductive resistances, there will be an E.M.F. in the battery to overcome these currents produced by the change of magnetisation, and the reversal of the current will be effected speedily. If, however, the number of cells is only sufficient to produce a current through the resistances of the electromagnet, the change will be much slower.

I have here an ordinary Westinghouse transformer which has an electromagnet in a ring form, but the iron of its core is divided into thin plates for the purpose of preventing currents in the iron itself. There is upon it a primary coil connected to the battery and a secondary coil connected to the galvanometer. I will first show you the effect produced when the battery current is produced by a battery of one cell giving about two volts. You observe that the current induced in the secondary coil takes a somewhat long time for its production and for its subsequent diminution—about 15 seconds. I will now connect it to a battery of high E.M.F., or rather to the mains which supply current to the building, and we will repeat the experiment with the same current in the primary coil. Observe the difference. The current increases more rapidly and dies away very much more quickly, taking in all about three seconds instead of 15 seconds, as before. I should perhaps here state that the sensibility of the galvanometer has been altered between the two experiments, so as to give a deflection of convenient size to be

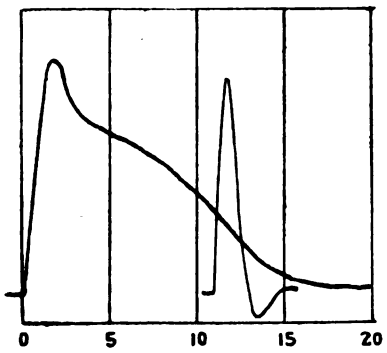

Fig. 1.

observed upon the screen. In the first case it is very much more sensitive than in the second. Exactly the same experiment can be shown to you in another form. These galvanometer deflections can be exhibited in the form of curves, in which the abscissæ represent times and the ordinates represent the deflections. The curve which I am showing you (Fig. 1) has actually been taken as a photograph, the plate being moved across the field with uniform velocity. On the same plate you see the curves which have been obtained with a larger E.M.F. and with a smaller one. The times at which the reversal occurred in each case are marked by the sudden change at the beginning of the curve. You see exactly the same thing as you saw upon the screen: the big battery makes the changes occur rapidly, the small battery allows them to occur more slowly. The dip of the curve for the large battery beyond the axes of the ordinates is not a real part of the phenomena. It is caused by the momentum of the moving part of the galvanometer.

In these experiments the iron has been divided in order to get rid of the particular effect about which I wish to speak this evening. Iron, as everybody knows, is a good conductor of electricity, not so good as copper, but still much better than any other substance than the metals. In a magnet, then, with a solid iron core, the outer portions of the iron are in a similar position to the copper coils surrounding the iron. On reversing the magnetising current, currents will be induced in the iron, and these currents will delay the changes of magnetic induction within them, and they will delay them the more the deeper in the iron is the point under consideration. I have in the room below a large magnet, which has been expressly constructed for the purpose of investigating the changes of induction which occur at different depths in the iron when the magnetising current is reversed. It is shown diagrammatically in Fig. 2. One view represents the vertical section of the magnet, the other the horizontal section. The magnet consists of a central cylinder of iron surrounded by an annulus with a large slab of iron at each end for the purpose of completing the magnetic circuit. Between the central cylinder and the annulus are placed the magnetising copper coils. In the solid cylinder holes are drilled at right angles to each other, and these holes meet within the iron. A strand of copper wire has been drawn in through the holes, and has subsequently been connected up so that the coils of the strand are in series with each other. In this way we have a coil surrounding a portion of the iron at 3, at 2, and at 1, of

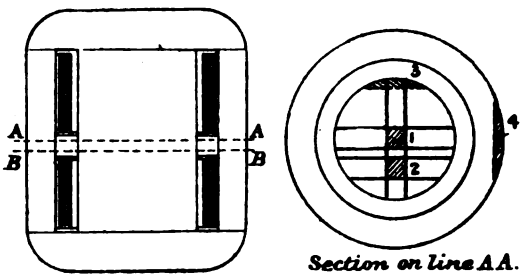

Fig. 2.

approximately the same area. If these coils then are connected to a galvanometer they will measure the changes of induction which occur in the areas 3, 2, and 1 enclosed, and we shall be able to show you the times at which the currents in the iron permit the effect of reversal in the copper coils to be manifest. We have, in addition, a coil, marked 4, in the outer magnet. Now, when the currents in the large copper coils are reversed, the magnetism or the induction in the coils 1, 2, 3, and 4 will also be reversed, but more slowly, and currents will be induced in these coils. I propose to show you the way in which these currents occur and are modified by the currents in the iron. We shall see that the changes in induction induce currents in the iron, and that these in their turn delay the changes in induction.

In order to give you a better idea of what is happening, we have provided three galvanometers. The galvanometers throw their images upon the screen at different altitudes. Now, what I want you to observe is this—that the disturbance of induction in the outermost coil occurs immediately

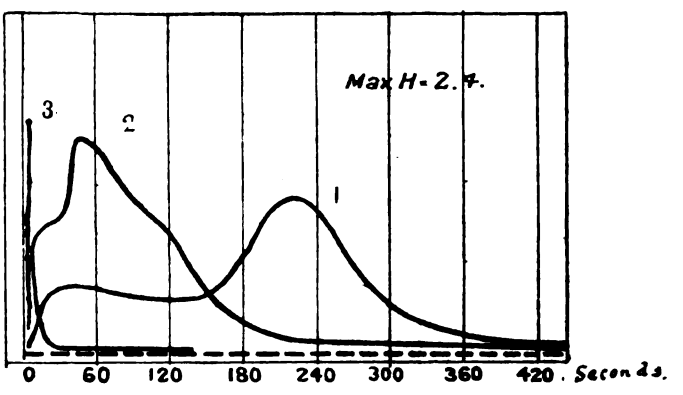

Fig. 3.

upon reversal of the current, and it occurs after some time in No. 2 coil, and after a much longer time in No. 1 coil, and also to observe the difference of the effects according as the magnetising current is large or small. In all these experiments a considerable battery power is used, and its excess of E.M.F. is taken up with non-inductive resistances consisting of lamps; that is in order to confine the effects to the currents in the iron, and to get rid as far as possible of the effects of induction in the copper coils themselves. We will begin with a somewhat low force, 2·4. You notice that, as shown in Fig. 3, the galvanometer of No. 3 coil is promptly deflected, and as promptly returns to zero, because there is no depth of iron outside it in which currents can circulate. No. 2 coil soon moves off to a substantial deflection, and presently, after 50 seconds have elapsed, it moves off to a greater deflec-

Digitized by Google

tion. The behaviour of No. 1 coil is not dissimilar, but it takes much longer. As in the case of the transformer, the same thing can be shown as a curve (Fig. 3). Observe the relation of currents in the exploring coils to time. No. 3 coil rises to a maximum, and at once ceases. No. 2 goes off fairly rapidly, dwells for a time, and then rises to a full maximum at about 50 seconds; whilst No. 1

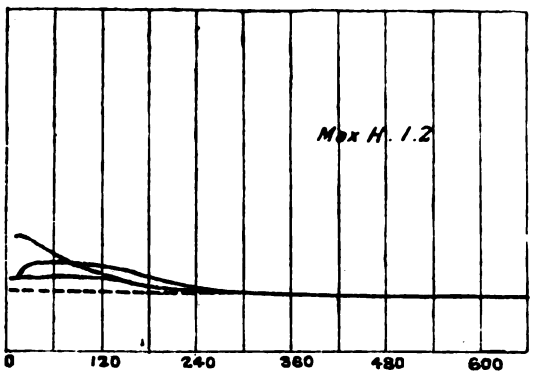

FIG. 4.

coil goes through the same events, but more slowly, as is shown by the increased abscissæ taking four minutes to reach its maximum. Here is a curve (Fig. 4) for a lower force, 1·2, half of the last: notice how great the difference—the maximum is reached much more speedily and the currents drop more slowly. Take a somewhat higher force, 6·0,

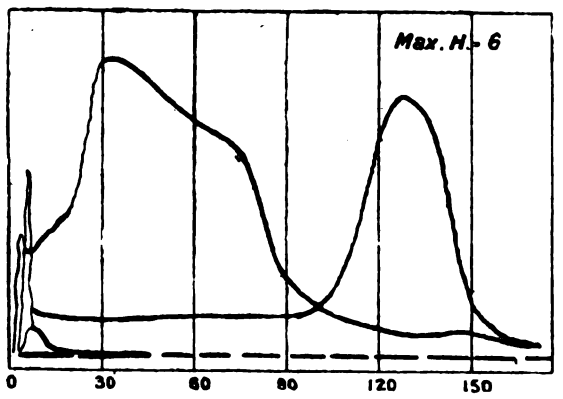

FIG. 5.

to see its effect on the galvanometers. The sensibility of No. 3 galvanometer is much less than that of Nos. 2 and 1, which are about the same. You see a new phenomenon develop: there is a first maximum in Nos. 2 and 1 coils, followed by a dwell and then a rise to a second maximum. Look at the corresponding curves

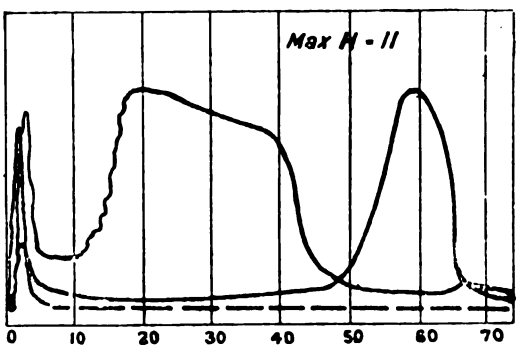

FIG. 6.

(Fig. 5). The maxima are occurring earlier than with the force of 2·4—that for No. 2 coil at 30 seconds instead of 50 seconds, and of No. 1, the centre coil, at 130 seconds instead of 240. Again take a higher force, this time 11 (Fig. 6): see how marked the first rise has become. On the curve notice that the maximum of No. 1 coil is as great as No. 2—with lower forces it has always been less. The highest force I shall show you is 24 (Fig. 7), and it is really the prettiest. The first maxima occur markedly at once. No 2 coil comes down to a small value, then rises to a substantial maximum in about 10 seconds, remains near its maximum value for 10 seconds, and passes away. Whilst No. 2 has been at its maximum, No. 1 has been quietly remaining undisturbed, and only when No. 2 has quite finished does No. 1 suddenly move off to a maximum

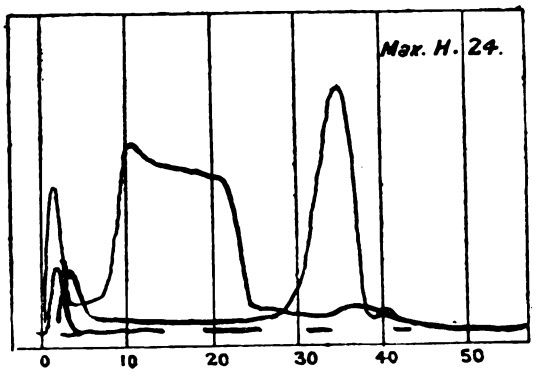

FIG. 7.

greater than No. 2 at 35 seconds and then very suddenly disappear. We must not leave this part of the subject without showing one experiment with No. 4 coil, which is placed in the annular part of the magnet. We will use the maximum force (24). The general character of the changes is the same as before, but in this case the mag-

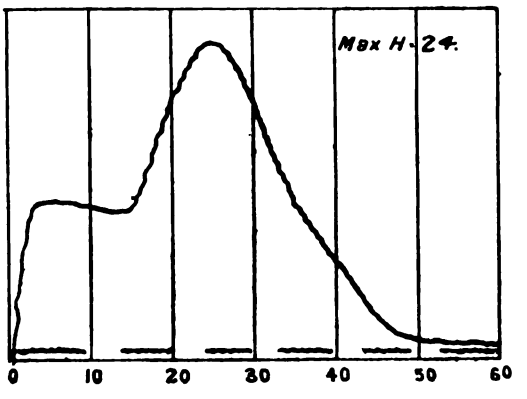

FIG. 8.

netism changes at once in the interior of the ring, and later at parts nearer to the outside. You see the same thing from the curve, Fig. 8.

I am afraid I can only give you a very general explanation of the peculiarities of these curves. I will first of all throw upon the screen a diagram (Fig. 9) showing what are known as cyclic curves of magnetisation. The vertical

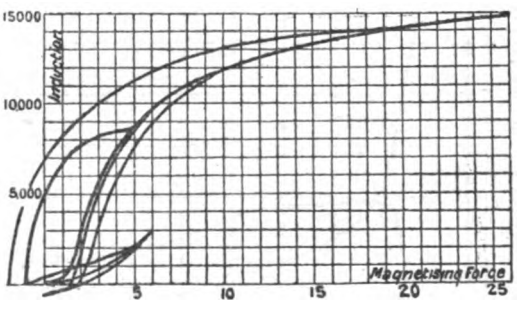

FIG. 9.

ordinates represent the induction, and the horizontal abscissæ the magnetising force. You will observe that when the magnetising force is small the ratio of induction to magnetising force is also small; that as the magnetising force increases this ratio is also increased for a time, but that, finally, it again becomes small. You will observe, further, that when the magnetising force is great the curve of magnetisation begins with a small rate of change, which

Digitized by Google

then becomes large, and which again becomes finally small. Now, the slowness of changes of induction depends upon the largeness of the ratio of induction to magnetising force, and, therefore, we should expect that when this ratio is small the changes would occur with comparative rapidity, and that when it is large they would occur more slowly. This is exactly what we have seen. With a small force the change shows itself almost at once; with an intermediate force the principal maximum occurs much later, and with a large force it is continuously being accelerated as the force becomes larger. The first rise that occurs with a large force is due to the early part of the curve of induction, where changes of induction are comparatively small,

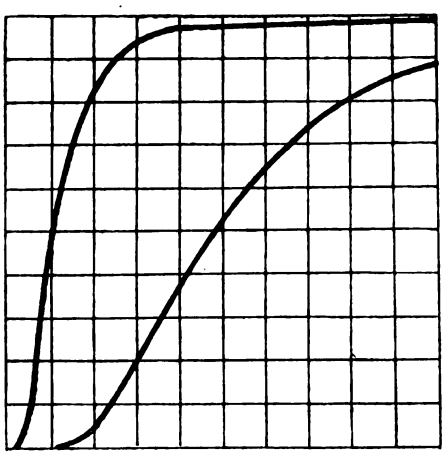

FIG. 10.

and where consequently the effects rush in rapidly. This first maximum is followed by a time of comparative quiescence, which is again succeeded by a second and large maximum caused by the full effect of the great changes of induction which have occurred, but which have passed in comparatively slowly; and then, finally, the change drops away to zero quite suddenly owing to the great rate at which the last part of the change has rushed in and pressed upon the parts which had occurred before it.

These phenomena of the times at which changes of induction occur in the cores of electromagnets have a close analogy to the retardation of signals upon cables. Many of you know if a battery is connected to a submarine telegraph cable, and if its connection is suddenly reversed, that the current throughout that cable is not reversed at once, but that it takes an appreciable time before the effect

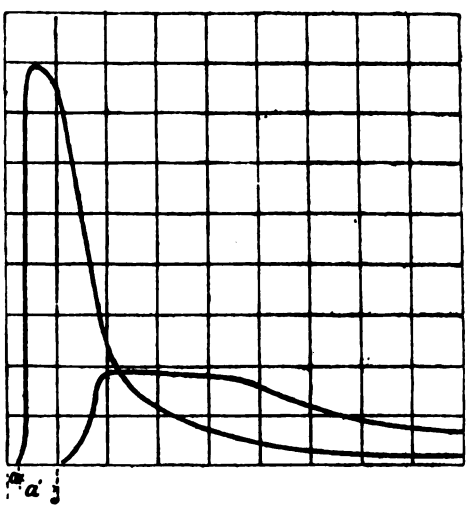

FIG. 11.

is perceptible at the far end of the cable. This retardation of the signal, as it is called, rapidly increases with the length of the cable. I will first of all show you two curves of arrival, as they are called, of the current in a cable (Fig. 10). In these curves the ordinates represent the currents, and the abscissæ represent the times. You will observe that there are two curves shown; one is for a length of cable double the other, the longer cable giving the slower times. Now, all that the curves in this form are capable of showing you is that with the longer cable the events are more retarded. In order to make them really comparable with the magnetic experiments, we must show a curve in which the abscissæ represent, not the currents, but the rate of change of current. We have such a curve here (Fig. 11). In this case the abscissæ represent the rate at which the current is changed, and the ordinates represent the time. This curve has a remarkable similarity to the magnetic curve with the lowest current. The similarity of the curves, as shown in Fig. 12, is quite sufficient to suggest an analogy between the phenomena which actually exist. I can show you the same thing in another way. There are in the library one of Lord Kelvin's syphon recorders, made by Messrs. Muirhead and Co., which will be at work after the lecture, and also an artificial cable, which has also been made by Messrs. Muirhead and Co. Curves can be obtained from the end and middle of the cable.

Magnetic experiments such as these have really a wide application. They are not restricted to the particular size of the cylinder upon which the experiment is made. If the cylinder is larger or smaller similar magnetic events will happen, but they will happen at times shorter or longer in direct proportion to the square of the linear dimensions of the cylinders—that is, to the areas of the cylinders. Hence we may boldly infer what will happen in magnet cores of dimensions too small to experiment upon or so large that they would be very costly to make. For example, suppose a core is made up of wires $\frac{1}{100}$th of an inch in diameter, we may expect that everything will go

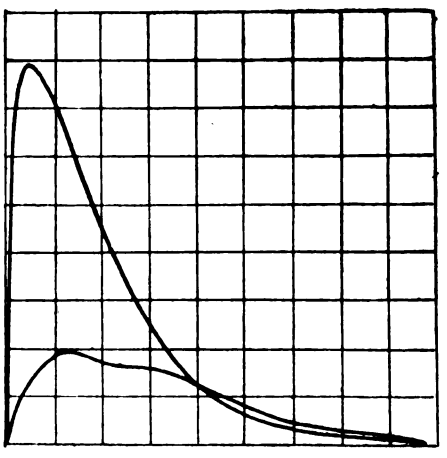

FIG 12.

on with the same currents around the core but 1,440,000 times as fast; with a force of 24, everything will be over at the centre of the core if the current is instantaneously reversed in $\frac{1}{40000}$th of a second.

One very practical application of these results is to the cores of transformers, but in this case we have not the sudden reversal of the magnetising current, but the current continuously varies from positive to negative and from negative to positive. It is not difficult to imitate these conditions on the slow scale which is suitable for our large magnet, but if I were to show you an experiment at an appropriate rate on the magnet which we used for reversals, I fear you would find the results intolerably tedious. It would take some minutes to get through a single reversal. I will, therefore, use a smaller magnet, 4in. instead of 12in. diameter, which will therefore get through the business nine times as speedily. I will first of all throw upon the screen a diagram (Fig. 13) which shows the method of the experiment. Here is the source of electricity, marked "dynamo"; here are resistances for regulating the current, marked "rheostat"; and here is a liquid reverser intended to reverse the direction of the current by continuous steps. It consists of two copper plates, to which the current is taken, and of two moving plates revolving between these plates, which plates are connected to the electromagnet. As the moving plates revolve, the current will diminish from a maximum in one direction to nothing, and will then increase to a maximum in the opposite direc-

Digitized by Google

tion. The electromagnet is marked "magnet," the secondary coils of which are not indicated in the diagram. Only one coil in the centre of the magnet is connected. We will now turn the reverser faster. You see, the variations of inductions diminish greatly—indeed, the induction at the centre of the core is but little affected by the changing current in the magnetising coils (change leads). We might

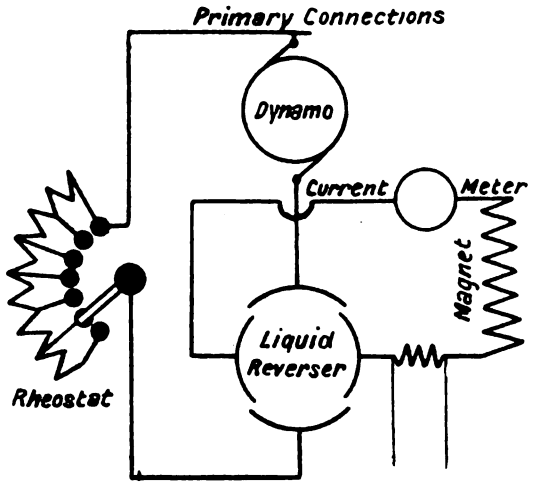

FIG. 13.

have tried three coils instead of one, but the experiment is a little confusing. If we had done so, we should have seen that the diminution of disturbance with increase of speed was less with No. 2 coil than with No. 1 coil, and that it had disappeared entirely with No. 3 coil, and we should further see that the current in No. 2 coil lay behind No. 3, and in No. 1 behind No. 2. I can show you the contrast more effectively with the Westinghouse transformer with

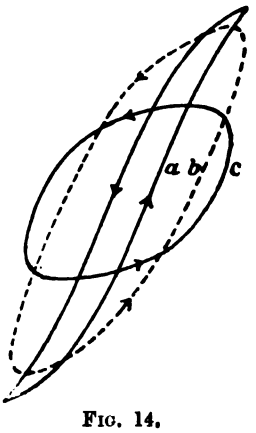

FIG. 14.

a divided core. This is now connected to the lowest galvanometer. We turn slowly; notice the deflection. We turn faster; you see the deflection is increased instead of diminished, as it was with the central coil of the solid electromagnet. Experiments such as these are at once applicable to transformer cores and the cores of dynamo machines. They show that in practice manufacturers have divided the iron about enough, and not too much.

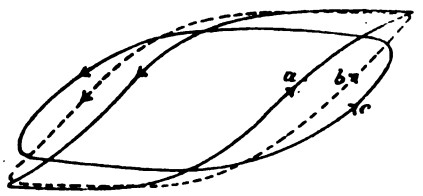

FIG. 15.

I have here on the table an instrument designed by Prof. Ewing for the purpose of describing the curves which express the relation between induction and magnetising force in iron. It served in Prof. Ewing's hands to illustrate the point which we have been discussing. I will throw upon the screen curves taken from Prof. Ewing's paper read before the Royal Society. The curves have been taken from solid samples of iron—I mean iron which is continuous, and not divided for the purpose of annulling the current in it. In the first curve (*a*, Fig. 14) we have the result in which the cycle has been passed through very slowly, and is the true curve of magnetisation. We have *b*, where the cycle has passed through in three seconds—and you will observe that the amplitude of the induction has diminished, and we have, lastly, the Curve *c*, where the period of the cycle is six-tenths of a second, and you will observe that it has much more diminished. This is owing to the fact that changes of induction in the centre of the iron hardly exist, and that therefore the total effect is materially diminished. The diagram (Fig. 15) is for steel. We have A, the natural curve of induction; B, the case when the period of the cycle is three seconds; and C, when the period is four-tenths of a second. Curves such as these, of course, very readily give you the average effects upon the whole mass of the iron. The curves which I have shown you give the particular effects of different parts of the mass.

In conclusion, let us indulge in a little wild speculation, not because it is probable that it is in any sense true, but because it is interesting. Suppose a magnet were made exactly like the one on which we experimented, but of the size of the earth, and that some mighty electrician generated such a current in its copper coils as would give a magnetising force of 2·5, and then reversed it, it would take some thousands of millions of years before the rate of disturbance at the centre attained its maximum value. The speculation I suggest is this: is it not conceivable that the magnetism of the earth may be due to currents in its material sustained by its changing induction but slowly dying away?

DEVIATION OF THE COMPASS.*

BY PROF. A. W. REINOLD, F.R.S.

By the deviation of the compass we mean the angle by which the compass needle errs from the magnetic meridian, or from the direction of magnetic north. On shore there is no deviation, nor is there on board a ship made of wood or other non-magnetic material. But iron is a magnetic substance, and on board an iron ship the compass needle is liable to be deflected from the magnetic meridian. The action of the iron is twofold: (1) some of it becomes permanently magnetised during the construction of the ship; (2) other is endowed with shifting magnetism, due to the changing position of the ship. The compass is affected by both causes, and there will generally be deviation; to what extent, and in what direction, depends upon a variety of conditions. Let me say at once that a magnetic needle on a compass card does not generally point exactly to the N.

A compass card is so balanced that it can only move on a horizontal plane; but that the earth's magnetic force is not entirely horizontal is shown by the fact that a magnet supported at its centre of gravity does not remain horizontal, but assumes a position in which its axis is inclined, in our latitude, at about 67deg. to the horizon. This angle is called the magnetic dip. The end of the magnet which points to the south is the end which is pulled down. The experiment of the dipping magnet tells us that the earth's magnetic fall is partly horizontal and partly vertical; the dipping needle, being acted upon by these two components, takes up a position which is neither horizontal nor vertical, but, in London, inclined at 67deg. to the horizon.

The apparatus which I have brought here for the illustration of our subject this evening consists of a skeleton binnacle, with the model of a ship's deck on the top. The whole can be turned about a vertical axis, the upper end of which is supported by a horizontal metal bar, with a recessed platform at the centre, which supports the compass. The binnacle is capable of carrying magnets and iron rods, horizontal and vertical, disposable in such a way as to imitate the magnetism of the ship and the various correctors. The compass consists of a small magnetised needle, attached at right angles to a glass, which carries a glass bulb and a mirror. The whole floats in water contained in a small glass cell. The stem has a small glass cup at the top, in which bears a steel point fastened to the lid. The buoyancy is such that the friction at the steel point is small. The advantages of the arrangement are sensitiveness, small friction, no torsion, considerable dead-beatness. A bar of unmagnetised soft iron becomes a magnet when submitted to the action of the earth's field. The maximum effect is produced when the bar is parallel to the lines of force in the earth's field—*i.e.*, parallel to the dip needle—but is nearly as great when the bar is held in a vertical position. The magnetism so acquired is only temporary, and disappears when the bar is held horizontally and perpendicular to the

* Abstract of a paper read before the Society of Arts, May 1.

Digitized by Google

meridian. The bar is also magnetised temporarily when placed horizontal and in the meridian. If the bar be again placed vertical and struck a few times with a mallet, the magnetism now acquired is greater than before, and is to some extent retained. Let the bar be now inverted. The end which was before uppermost is now below. The effect produced on the test-needle is due to the difference between its retained and its temporarily acquired magnetism. That the retained magnetism is not permanent is shown by striking the bar in its new position. It may again be restored to the neutral or non-magnetic condition by a few blows when it is held horizontal and near the meridian.

The effect of twisting an iron rod or wire in a magnetic field is similar to that due to percussion. But if the iron is soft the acquired magnetism is soon got rid of. Suppose that similar experiments were made on a bar of hard iron—*i.e.*, on iron partaking more or less of the character of steel—we should find the inductive action of the earth decidedly less than in the case of soft iron or mild steel; the effect of hammering would not be so marked. But the magnetism acquired by hard iron when submitted to long-continued and violent hammering, such as the plates of a ship receive when riveting, etc., during the construction of a ship, is very difficult to shape out. A large proportion of it is practically permanent. We thus see how a ship becomes a permanent magnet. Each plate, or rib, or beam, each bulkhead or watertight division, remains in a fixed position while heavy blows are poured upon it. The iron ship becomes a huge magnet.

I spoke of the effect of an iron ship on a compass on board as being twofold—viz., that due to the permanent magnetism of the ship, and that due to temporary induction in soft iron. We have now to consider the second of these, and in doing so we will take in order the action of the west and horizontal components of the earth's magnetism. Every vertical mass of iron in the ship—the ship's sides and ribs, fore and aft and transverse compartment divisions, masts, funnels, etc.—will be magnetised with (in these latitudes) north at the top and south at the bottom. If all the iron is symmetrically disposed with regard to a central vertical fore and aft plane, it may, so far as its action on the compass is concerned, be supposed to be replaced by a single vertical rod with one of its extremities in the fore and aft line through the compass. Whether this imaginary resultant rod is foreward or aft of the compass will depend upon where the compass itself is placed on the ship. The effect on the compass of all the vertical iron is then the same as that of a single vertical iron rod in the fore and aft line through the compass. As the ship swings completely round this will produce a complete error of precisely the same character as that we have already considered—viz., semicircular.

The next point to consider is the action on the compass of magnetism induced in the iron of the ship by the horizontal component of the earth's magnetism. There is ordinarily a large mass of soft iron in a ship in which horizontal induction can take place; but whatever its disposition, provided it be symmetrical, with regard to the fore and aft line, its resultant effect on the compass may be considered as due to, and may be represented by, iron rods, in the plane of the compass, and in the fore and aft and transverse lines through the centre of the compass. Such rods will produce no compass error when the ship is magnetic north and south, or magnetic east and west. But in intermediate positions the induced magnetism will deflect the needle, and if the error is easterly when the ship's head is in the north-east quadrant, it will also be easterly when the ship's head is in the south-west quadrant, and will be westerly in the other two quadrants. This error is called quadrantal, because it changes sign in every quadrant. If easterly, with the ship's head in the north-east quadrant, it is said to be positive. Isolated rods in the fore and after line produce positive and in the athwartship line negative quadrantal error. This suggests a mode of correcting the error by employing masses of iron, generally spheres, tolerably close to the compass. If the error is positive, the spheres must be placed port and starboard of the compass; if negative, in the fore and aft line. We have supposed the iron of the ship to be symmetrically arranged with respect to the fore and aft vertical plane through the compass, and though this is generally the case, it is not necessarily so. There may be a mass of iron—say, an iron pinnace or launch—stowed on one side of a ship in the neighbourhood of the compass not balanced by an equal mass on the other side. Such unsymmetrically-disposed iron gives rise to a quadrantal error, which is a maximum at the cardinal points, and sometimes also to a small constant error—*i.e.*, one whose magnitude and symmetry are independent of the direction of the ship's head.

We have thus brought under view the various causes producing compass error on board an iron ship. They are summed up in the formulæ—

$$\delta = A + B \sin \alpha + C \cos \alpha + D \sin 2\alpha + E \cos 2\alpha,$$

in which δ = the deviation, when α = the compass course; A, B, C, D, E are the coefficients; A is the constant coefficient; B and C are the fore and aft and transverse components of the semicircular error; D and E refer to the quadrantal error, D being due to symmetrical and E to unsymmetrical iron; A and E may generally be neglected.

The method of compensation now universally adopted was first employed in a systematic manner by the late Sir George Airy, and has been brought to its present state of efficiency by Lord Kelvin. The formulæ show us that there are only three components of the error with which we have to deal—viz., B, C, and D, B and C referring to semicircular and D to quadrantal. B arises from fore and aft magnetic forces, due to vertical iron and permanent magnetism of ship; C from transverse forces, due to permanent magnetism only. The component C can be corrected by permanent steel magnets, placed in the binnacle at a suitable depth below the compass. Similarly B, if it were due to the permanent magnetism of the ship only—*i.e.*, if inaction in vertical iron had no part in producing it—might be corrected by fore and aft magnets suitably placed in the binnacle. But if part of B is due to vertical iron, that part ought to be corrected by vertical iron, and the remainder only by magnets. The difficulty is to know how much of the observed error is due to each of the above causes, and this one cannot know until observations have been taken in two widely different latitudes. On the magnetic equator there is no vertical force, and therefore the whole of B observed on the magnetic equator must be due to permanent magnetism, and should be corrected by steel magnets. If on board such a ship, sailing northwards from the equator, B should be found to have a sensible and increasing value, we should know that it was due to vertical induction only, and we should correct it by vertical induction—*i.e.*, by placing a vertical rod of iron of suitable length close to the binnacle, either forward or aft of it, so that its effect should just balance that of all the vertical iron of the ship. Such a rod is called a Flinders bar. As used in Lord Kelvin's binnacle, it is 24in. long and 3in. in diameter, and is made up of pieces, the longest of which is 12in. long and the shortest $\frac{3}{4}$in. We have thus by permanent magnets, Flinders bar, and the quadrantal spheres balanced every cause of compass error, and compensation thus effected will hold good for all latitudes, so long as the ship remains on an even keel.

HEELING ERROR (STANDARD COMPASS).

Ship Built in Great Britain, and Heeling (in N. Latitudes) to Starboard.

Causes.	Symbol.	Direction of error.	Error a maximum.	How compensated.
Principal.				
1. Transverse horizontal beams becoming inclined. Induction by earth's vertical force	e	To windward.	When ship's head is N or S varies, as cos α = azimuth of ship's head measured from N. by compass	Partly by "quadrantal" spheres
2. Iron perpendicular to deck vertically below compass..	k	Windward.	N or S.	By magnet or magnets, red pops upwards (generally) placed vertically in binnacle below compass.
3. Force perpendicular to deck due to ship's permanent magnetism	R	Windward (generally).	N. or S.	
Subsidiary.				
4. Iron perpendicular deck *not* vertically below compass..	c	To E.	E. of W. $\alpha \sin^2 \alpha$.	Flinders bars.
5. Horizontal fore and aft iron	g	To W. if compass is near stern of ship; to E. if compass near bow	N. or S. $\alpha \cos^2 \alpha$.	Compensation not generally attempted.

The table exhibits in a tabular form the principal and secondary causes of heeling error, the direction of the error in each case, the direction of the ship's head when the error is a maximum, and the mode of compensation. We will not here

Digitized by Google

trouble ourselves about the subsidiary causes, but in the case of the others it is clear (1) that generally the error is to windward, (2) that it is a maximum when the wind lies north and south, and vanishes in the east and west direction. Next, with regard to compensation. Errors 1 and 2 are caused by vertical induction in iron, and should be similarly compensated. And to a certain extent they are so; for consider the iron spheres which correct the quadrantal error. These would by themselves produce a heeling error to leeward, and therefore act against the other causes. The amount of negative error produced (or positive error compensated) may be calculated when the size of the spheres and their distance from the compass are known, and the value so deduced agrees fairly well with that experimentally observed. The spheres correct from five to seven minutes of heeling error, per degree of heel, for each degree of quadrantal error they correct. Thus, suppose the quadrantal error to be 11deg., the 8½in. spheres by which this is corrected would by themselves produce a heeling error to leeward of about 1deg. (per degree of heel), and will therefore correct an error of 1deg. to leeward.

The remainder of the error—which may be the principal part—is corrected by permanent magnets, one, two, or three in number, placed in a brass tube which can slide up and down a vertical central channel in the binnacle. The empirical method of correcting the error, and at first sight the simplest, would be, assuming there is no error on an even keel, to place the ship N. and S., cause and maintain a certain heel (say to starboard) of 10deg., place magnets with red poles upwards in the receptacle provided for them, and raise or lower them until the error disappears; but owing to the difficulty and expense—especially with large ships—of actually heeling the ship, this method is not employed. One of the plans generally adopted—the simplest of them—is to determine the vertical magnetic force on shore by means of a suitable dip needle. The latter is then brought on board, placed in the binnacle (the compass bowl having been removed), so that the dip needle occupies the same position as the compass needle. The vertical connecting magnets are then raised or lowered until the vertical force on board is equal to that on shore, modified by the application of a small correction on account of the screening action of the iron of the ship. The dip needle has a sliding weight attached to it. This, in the experiment on shore, is moved until the needle is horizontal; in this case the mechanical couple, due to the earth's vertical force, is balanced by the leverage of the sliding weight. On board, the vertical magnets are moved until the horizontal position of the needle, which will probably have been disturbed, has been restored. The error is now corrected.

In the method of correcting the semicircular and quadrantal errors of the compass which I have described, it is necessary that the true magnetic bearing of some object visible from the ship should be known, so that the ship may be placed successively magnetic north and south, and magnetic east and west. It is possible, however, to completely correct the compass when nothing is visible outside the ship—*e.g.*, in a fog or at night. The correction is effected by means of an instrument called a deflector. On the table are two forms of the instrument, one Lord Kelvin's, consisting of two magnets hinged together at their extremities, the free ends being adjustable at a greater or less distance apart. The other form has been designed by Dr. Waghorne, assistant professor of physics at the Royal Naval College, Greenwich. It consists of two short parallel magnets, movable up and down a movable stem by a rack and pinion arrangement.

The mode of procedure is as follows: Put the ship's head north by compass and keep her there by means of an auxiliary compass. Place the deflector on the glass cover of the compass bowl, and arrange it so that the compass card is turned round through 90deg. Lord Kelvin keeps his instrument in a fixed position on the bowl, and adjusts by altering the distance between the poles of the deflector magnets; this can readily be done by means of a double screw. Dr. Waghorne, on the other hand, rotates his deflector, without altering the position of the magnets on it, until the deflection of 90deg. is obtained, and reads off the angle (say α) the deflector makes with the compass needles. Similar experiments are made with the ship's head south by compass, and another angle, β, is read off. The deflector is now set on an angle whose sine is the mean of the sines of α and β, and fore and aft magnets introduced into the binnacle until the deflection of the card is again 90deg. The fore and aft component of the semicircular error—so far as it is due to permanent magnetism only—is now compensated. In an exactly similar way, by taking observations with the ship's head successively east and west, the transverse component can be corrected.

The use of these instruments, though requiring care and patience, is not by any means difficult, and is soon learnt. Further, by the sine-deflector, it is possible, without disturbing or altering any correctors in the binnacle, to determine the coefficients, B, C, and D, and so to supply the means of computing the error on any compass course. This use of the deflector may be valuable in cases where it is undesirable to interfere with the correctors.

PHYSICAL SOCIETY.

An ordinary meeting of this society was held on April 26, Mr. Walter Baily, vice-president, in the chair.

Prof. S. P. Thompson read a note on "**A Neglected Experiment of Ampere.**" Ampère, in 1822, made an experiment which, if it had been properly followed up, must have led to the discovery of the induction of electric currents nearly 10 years before the publication of Faraday's results. While attempting to discover the presence of an electric current in a conductor placed in the neighbourhood of another conductor in which an electric current was flowing, Ampère made the following experiment. A coil of insulated copper strip was fixed with its plane vertical, and a copper ring was suspended by a fine metal wire so as to be concentric with the coil and to lie in the same plane. A bar-magnet was so placed that if an electric current was induced in the suspended ring a deflection would be produced. No such deflection, however, was observed. In 1822, in conjunction with De la Rive, Ampère repeated this experiment, using, in place of the bar magnet, a powerful horseshoe magnet. He describes the result in the following words: "The closed circuit under the influence of the current in the coil, but without any connection with this latter, was attracted and repelled alternately by the magnet, and this experiment would consequently leave no doubt as to the production of currents of electricity by induction if one had not suspected the presence of a small quantity of iron in the copper of which the ring was formed." This closing remark shows that they were looking for a permanent deflection. When, however, Faraday's results were published in 1831, Ampère, after again describing the experiment made in 1822 by himself and De la Rive, says: "As soon as we connected a battery to the terminals of the conductor the ring was attracted or repelled by the magnet according to the pole that was within the ring, which showed the existence of an electric current produced by the influence of the current in the conducting wire." Verdet, when describing the above experiment, falls into a curious error. He says the apparatus consisted of a ring of fine copper wire suspended by a silk thread in front of the pole of an electromagnet in such a way that the plane of the ring was parallel to the plane of the turns of wire on the electromagnet. On making the current the ring is said to have been repelled, but this deviation did not persist, and on "breaking" the current the ring was attracted, also only momentarily.

Mr. Blakesley did not feel quite confident that in Verdet's form of the experiment there could ever be attraction. He also pointed out that with an alternating current the disc would tend to set itself parallel to the lines of force of the electromagnet. With reference to repulsion by alternating currents in one of Elihu Thomson's experiments, where a sphere is supported over an alternating pole, a screen being placed so as to partly shield this sphere, there is generally a mis-statement as to the direction in which the sphere rotates. It rotates in such a direction that the part of its surface next the magnet moves towards the edge of the screen.

Dr. Burton said that from the fact that when the current in the electromagnet in Verdet's experiment is broken, the induced current in the ring is in the same direction as the current in the magnet, and the ring will be attracted.

Mr. Boys confirmed Dr. Burton's statement. He recommended setting the ring at an angle of 45deg. to the lines of force, under which circumstances a rotation would be obtained. A distinction must, he pointed out, be drawn between such an experiment as that of Verdet's and those of Elihu Thomson's. The repulsions observed in these latter were only due to the "lag" in the induced currents caused by self-induction. The best materials to use for all such experiments were magnesium and aluminium, since for a given mass these had the highest conductivity.

Mr. W. G. Rhodes read a paper entitled "**A Theory of the Synchronous Motor.**" The object of this paper is to give as simple a treatment as possible of the mathematical part of the subject, and to give theoretical proofs of some experimental facts. Starting from the energy equation—

$$p + c^2 R = C E \cos \Psi,$$

where p is the output of the motor, R the resistance of the armature, c the current through the armature, E the E.M.F. applied to the motor terminals, and Ψ the phase difference between c and E, the cases of maximum output, zero output, minimum current at zero power, and maximum phase difference between c and E are considered. These results are for the most part obtained directly from the energy equation. The latter part of the paper is devoted to a discussion of the phase relationships between the current and the E.M.F.'s in a plant consisting of a generator and motor, and to the variations in the armature reactions in both generator and motor. A theoretical proof is given of the fact, observed by Prof. Silvanus Thompson and others, that an over-excited synchronous motor acts as a condenser, and tends to make the current lead before the generator's E.M.F.

Prof S. P. Thompson said that the mathematical part of the paper was much simpler than that in previous investigations on this subject, and the method of arriving at the results by rejecting imaginary roots of the equations was particularly neat and instructive. The part of the paper relating to armature reactions and phase relationships was quite new. Two results deserved special attention: first, that the maximum current at zero power was the same as if the circuit was non-inductive; second, that the maximum current at zero power was double the current corresponding to maximum output.

Digitized by Google

Mr. Blakesley said that the paper did not consider the stability of the system, and he thought some of the results corresponded to regions of unstability.

A paper by **Mr. Bryan** "**On a Simple Graphical Interpretation of the Determinantal Relation of Dynamos**" was, in the absence of the author, read by Dr. Burton. The relation is worked out for two specially simple systems, possessing one degree of freedom: (1) a particle moving in a straight line with uniform acceleration; (2) a particle moving to and fro along a straight line with an acceleration directed towards a fixed point on the line, and proportional to the distance from that point (simple harmonic motion). On constructing a diagram in which the abscissæ represent values of the single co-ordinate of the particle, and the ordinates corresponding values of the momentum, the determinantal relation becomes equivalent to the constancy of the area of a certain elementary parallelogram. In case (1) this parallelogram moves along a parabola, experiencing a shear as it goes, while in case (2) there is no distortion, the (rectangular) parallelogram revolving about the origin of the diagram as if rigidly attached to an inextensible radius vector.

THE SELECT COMMITTEE ON TELEPHONY.

The Select Committee of the House of Commons which is engaged on an enquiry into the sufficiency of the telephone service met again on Friday, Mr. A. Morley presiding.

The evidence of **Mr. Dickinson**, deputy-chairman of the London County Council, was resumed. He stated, says the *Times*, that the general tendency of the charges contemplated in the agreement between the Post Office and the National Telephone Company was to increase the trunk charges. The Council also felt that exception might be taken to the clauses which contemplated that where a message was sent from the National Telephone Company's office in London to the office of another company in another town a terminal charge should be made. The only remedy he could suggest was that competitors should be put on an equal footing with the National Company. The scarcity of subscribers in London he attributed to two facts—first, that the service was bad; and secondly, that the charges were very high as compared with the charges made in continental cities. The committee of the Council which was appointed to look into the question had received three reports from three separate engineers, and those reports showed that London could be telephoned now for 10,000 subscribers at a subscription of something under £10 a year. The reports dealt with the area of the county of London. Witness then dealt with the National Company and the old United Company in detail. At the time of the amalgamation the United Company was paying something like 15 per cent. on its capital. The capital had since been largely increased. Competition was the best way of developing the telephonic service, as long as it was not taken over by the Government. If the Government did not take over the telephones he would permit the municipalities to do so. The London County Council was not prepared with any specific allegations of imperfect service by the National Telephone Company.

Sir E. H. Carbutt, representing the London Chamber of Commerce, was next called. He said that he was chairman of the engineering and allied trades section of the Chamber, and was a member of the committee of the council specially appointed to consider the question of the agreements. The Chamber adopted a series of resolutions on the subject. One was in favour of State acquisition, a second was in favour of letting matters alone, in view of Sir W. Harcourt's statement in the House of Commons, and a third was in favour of encouraging properly-controlled competition. The Chamber, said the witness, regarded the telephone as being in its infancy, and believed that with proper facilities it would prove of immense assistance to trade. As to "varying rates for limited service," the idea was that others besides the rich might be enabled to use the telephone if communication were established in small areas. Persons might, for instance, be put in communication with the local tradespeople; and in the case of agricultural districts, a number of farms might be connected with the creamery which they served. The cost of making such a telephonic connection would not be more than £100 for about 10 farms. This work could be done by small companies, and the Postmaster-General would control competition in the interests of the public. London ought to be dealt with on a separate basis from the rest of the country. If competition were permitted, some standard regulations, applicable to all towns, should be drawn up.

Major Flood Page also gave evidence as to the resolution passed by the London Chamber of Commerce. He said that they were the result of a long discussion, and represented the compromise of widely different views.

The committee adjourned, after sitting for some time with closed doors.

The Select Committee sat again on Tuesday, Mr. Arnold Morley presiding.

Mr. Berridge, chairman of the Street Committee of the Commissioners of Sewers of the City of London, said that the present service was very inefficient in consequence of the lines being frequently blocked. He paid £17 a year under a five years' agreement. He was authorised to say that the Commissioners of Sewers were very anxious to get a good service at a reasonable rate, and a resolution had been passed by his committee to the effect that £10 a year would be a reasonable rate. The Commissioners had been in negotiation with the City of London Electric Lighting Company for the use of their tubes by a company that would supply a service at a reasonable rate, and those negotiations were still going on. The Commissioners of Sewers were the road authority in the City and had control of the streets, and that control ought to be maintained. He thought the Commissioners ought to have the right to apply for a license if they thought fit to do so, but as far as he knew it was not now their intention to apply. For his own part he would like to see the telephones taken over by the Government. If a license were granted to the London County Council, he should certainly say that the Commissioners would not hand over to them the control of the streets.

Mr. John Archibald Dow, a coalmaster in Glasgow, said he had used the telephone in that city for 11 years, and had always found it a very good service, though there were occasional breakdowns. To give municipalities licenses was, in his opinion, a retrograde step. He would rather see all the telephones in the hands of the Government. His subscription was £10 a year. He came to give evidence at the request of the National Telephone Company.

Mr. Robert Caird, superintendent of the Glasgow Omnibus Company, also expressed general satisfaction with the service at present, and deprecated the granting of a license to the Corporation.

Mr. James Patterson Waldie, a partner in a firm of coal-owners, and **Mr. Alexander Risch**, editor of an Edinburgh evening newspaper, expressed themselves as well satisfied with the efficiency of the present service in Edinburgh; and **Mr. Alexander Hay Moncur**, ex-provost of Dundee, and **Mr. James Crombie**, a merchant and shipowner of Aberdeen, also gave evidence in favour of the existing service in Dundee and Aberdeen respectively.

LEGAL INTELLIGENCE.

WYNNE v. HASLAM AND CARTWRIGHT.

This case, which lasted two days, was tried last week at the Liverpool Assizes. The action was one of a personal nature, but is nevertheless of importance to municipalities and their officials. The plaintiff was Mr. William Richard Wynne, formerly electrical engineer for Bury, and the defendants were Mr. John Haslam, town clerk of Bury, and Mr. Joshua Cartwright, the borough engineer. The defendants had the support of the Corporation, the Mayor and Electric Lighting Committee strongly supporting the course they had adopted.

It appears that somewhat strained relations had existed for some time between Mr. Wynne and other officials, due to the objection of the former to submit himself to the latter, as the Corporation considered he should do. The upshot was that Mr. Wynne received a month's notice. This led to the relations becoming more strained, and Mr. Wynne felt aggrieved because he was locked out of a room. Incidents then occurred which led to the present action. Mr. Wynne at the last assizes raised an action against the Corporation for wrongful dismissal, and received damages, and now proceeded against the gentlemen named above.

Mr. Pickford, Q.C., in his opening statement for the plaintiff, said that this was an action for damages against the two defendants, arising out of the engagement of the plaintiff by the Bury Corporation, and the dismissal of the plaintiff by the Bury Corporation from his position of electrical engineer of the Corporation. Mr. Haslam was the town clerk of Bury, and the defendant Mr. Cartwright was the borough surveyor. The cause of action was threefold. In the first instance, Mr. Wynne claimed damages against both defendants for having maliciously induced the Corporation to terminate his employment as electrical engineer to them. The defendants said, shortly, that they did nothing of the kind. Then, as to the action against Mr. Cartwright, the plaintiff said he slandered him, and spoke defamatory words of him to the Electric Lighting Committee of the Council, who were the immediate employers of the plaintiff. The words complained of were that Mr. Cartwright had at the committee meeting said that it had been found necessary to lock up Mr. Wynne's room, and the counsel submitted that to Mr. Wynne had been imputed conduct which obliged him to lock him out of the occupation of the room. The defence which Mr. Cartwright set up was that he was privileged on the occasion—that was to say, that an official was speaking to the Electric Lighting Committee of the Corporation; that if he spoke *bona fides*, even although what he might say was inaccurate, he would be protected With regard to the assault (the cause of complaint against Mr. Haslam), the plaintiff was in Mr. Cartwright's room, and the town clerk turned him out. The plaintiff said whether the town clerk did right or not, he certainly did it with too much violence.

The defence was conducted by Mr. Russell and Mr. McCall.

Mr. Justice Hawkins, in summing up, stated that it was regrettable that the action should have been brought. He pointed out that Mr. Wynne was attracted by an advertisement to make application for the post of electrical engineer to the Bury Corporation, but the Bury Corporation had in their employ at that time Mr. Cartwright, who was their surveyor, and who had been with them for 15 or 16 years, and had served them faithfully at the head of his own department. When he entered the service of the Corporation, Mr. Wynne may have entertained the notion that he was to have an equal position with that of the old surveyor, but certainly that was not their intention. Their intention was that Mr. Wynne, although placed in a responsible position in their service, should be below in point of position the surveyor who

Digitized by Google

had been trusted by them for 15 or 16 years, that he should have a subordinate place—not, indeed, to be in the position of a mere clerk—but that he was to be under the surveyor and under the surveyor's directions. There was early in the engagement discussion as to whether or not Mr. Wynne would be prepared to go on, whether he would act in a subordinate position to the surveyor, and there was a very decisive answer in the negative on the part of Mr. Wynne that he would not do so. However, he did go on as far as he could, reluctantly and unwillingly serving the Corporation, and, as far as he could bring himself to do so, submitting to the authority of the surveyor, until about the month of October, when these final differences occurred between them, and he was dismissed from the service. The judge stated that Mr. Wynne should have acted harmoniously with the other officials, and left it for the jury to decide upon the three issues before them.

The jury returned a verdict for the defendants on the first two counts, and on the third count (that of assault) a verdict for the plaintiff of 40s. damages.

Mr. Russell asked for judgment for the defendant on the record as it stood, to which Mr. Justice Hawkins assented.

The real question at issue was whether an official holding a subordinate position under a municipality should or should not be subordinate to a superior official. The verdict has been to the former effect, and it is satisfactory to note that the Bury Corporation have supported their town clerk and borough surveyor in this affair.

ACTION TO RECOVER CALLS.

Before Mr. Justice Wills, the three cases have been heard of the London Metallurgical Company *v.* Sherrard O. Cowper Coles; same *v.* Sir B. W. Walker; and same *v.* Samuel Hood Cowper Coles. The question involved was as to the liability of holders of certain shares to pay calls, the three actions being brought by the liquidator of the plaintiff company. The Metallurgical Company was incorporated on December 8, 1890, and an order for its winding up was made on May 18, 1893, a liquidator being appointed on September 21, 1893. The first-named defendant was an engineer and an inventor, and in August, 1891, he was allotted 275 shares of £10 each, fully paid up, in the plaintiff company in respect of certain patents which he transferred to them. The agreement between the parties in regard to this transaction was never registered. On December 9, 1893, notice was given by the liquidator to Sherrard Cowper Coles of the settlement of the list of contributories. That list was settled on January 31, 1894; on February 6, 1894, notice was given to him of it, and on May 29 there was an order for the liquidator to make a call, of which due notice was given. The first defendant retained 108 shares, for which it was now sought to fix him with a liability for calls, they being treated as vendors' shares. Objection was taken on his behalf that the companies winding-up rules had not been complied with; but this contention was abandoned, the defence relied upon being that he was allotted the shares fully paid up as consideration for patents in respect of which he had never been paid, and that if the liquidator were now to be allowed to dispose of the patents, then the defendant had a lien on them, and he set up a counter-claim in their regard. The defendants in the second and third actions were brother-in-law and brother respectively of the first defendant, Sir W. B. Walker being a naval officer. They were simply transferees for value, and they had no notice whatever at the time of the transfer of the shares that there was any liability whatever upon them, but they took them as fully paid up. On the other hand, stress was laid on the fact that the agreement between the first defendant and the company was not registered, and on this account, it was said, the company endeavoured to escape from its obligations to pay the first defendant for the patents he had transferred to them.

At the conclusion of the arguments his **Lordship** gave judgment in the first action for £1,080 for the plaintiff, and decided that the defendant had no lien on the patents. In the second action he gave judgment for the plaintiff for £30, without costs, and in the third judgment for the plaintiff for £50, with costs.

COMPANIES' MEETINGS AND REPORTS.

EASTERN EXTENSION TELEGRAPH COMPANY.

The forty-third ordinary general meeting of the shareholders of this Company was held on Wednesday at Winchester House, Old Broad-street, under the presidency of Sir John Pender, M.P.

The **Chairman**, in moving the adoption of the report and accounts, said that the gross receipts for the half-year were £261,322, against £251,689 for the corresponding period of 1893, the increase being entirely due to the large Government and Press traffic carried on with China and Japan since the commencement of hostilities between those two countries. The working expenses for the half-year were £89,740, against £76,574 in the corresponding half-year of 1893. Of that sum nearly £9,000 was due to the increased cost of repairs and the maintenance of cables, while the balance of the increase was due to the opening of new stations and the establishment of electric lighting at various other stations. Comparing the figures for the whole of the year with the previous year, their gross receipts for 1894 were £509,003, against £509,684 in 1893; while their working expenses were £170,035, against £154,803. The usual interim dividend had been declared, and, with the balance they proposed to pay after that meeting, they would have declared a dividend for the year of 5 per cent. In addition to that they proposed to pay a bonus of 4s. per share, equal to another 2 per cent., making a total dividend for the year of 7 per cent. A balance of £89,686 was carried to the general reserve fund, which now stood at £641,598, after charging the past year with £100,000 in part payment of the new Singapore and Hong-Kong cable.

The **Marquis of Tweeddale** seconded the motion, which was put and unanimously adopted.

Mr. C. W. Earle and Mr. G. G. Nicol (the retiring directors) were reappointed, as also were Messrs. Deloitte, Dever, and Co., and Messrs. Welton, Jones, and Co. as auditors.

NORWICH ELECTRICITY COMPANY, LIMITED.

The annual meeting of the shareholders of this Company has been held in Norwich to receive the report of the directors, which was as follows: The directors have much pleasure in presenting their third annual report, which shows the great progress and increasing prosperity of the Company. They consider it highly satisfactory and full of promise for the future that this new enterprise should have reached a dividend-paying stage within 15 months of the commencement of its operations. On January 1, 1894, the station had only been at work for three months, so that the results of but one quarter of last year can be compared with those of the corresponding quarter of 1893. This comparison shows that for this period the current generated and the income derived from its sale had more than doubled. At the end of 1894 the Company had six engines and three boilers at work, compared with three engines and two boilers a year before. It has been found necessary also to erect a fourth boiler as a reserve in case of either of the others breaking down. A number of fresh customers have applied for current since January 1, and applications are still being made, so that the present machinery will not be sufficient to carry the station on through the next winter. The amount of current produced during the first 11 weeks of the present year shows the gratifying increase of 82 per cent. on the corresponding period of 1894, and it is not expected that the working expenses of the Company will increase in anything like the same proportion as the revenue. A year ago one place of worship had been lighted by electricity; now there are four, including the new Catholic cathedral. The advantages of the electric light are so decided, and the cost of it compares so favourably with that of gas, that the directors believe a considerable income will be eventually gained by lighting such buildings. At present the Company has nearly 4¾ miles of mains, compared with about 2¾ miles in 1893, but there are other streets than those already laid where a profitable demand for current may be expected. The machinery continues to work satisfactorily, and it gives results which will compare favourably with those of other electric stations. Much credit is due to the engineer and the staff for the efficient manner in which the business of the Company has been carried out during the past year. The result of last year's trading, after paying station and office expenses, and interest due to the bank, shows a net profit of £1,356. 11s. 4d., to which must be added £237. 9s. 10d., the balance brought forward from last year, making a total of £1,594. 1s. 2d. standing to the credit of the profit and loss account. Out of this the directors proposed to wipe off the preliminary expenses (£382. 4s. 2d.), and to place a sum of £400 to a reserve fund for machinery renewals, leaving £811 17s. available for a dividend. The directors propose to pay a dividend for the year 1894 of 3 per cent, free of income tax, and to carry forward the balance of £112. 5s. 8d. The directors have thought it better not to ask the public for fresh capital until they could show that the Company was likely to be a success, as to which, however, they had from the first little doubt, preferring to obtain the money they required in the form of a temporary loan from their bankers, but the time has now come to invite applications from the shareholders and the public either for further ordinary shares or for 4 per cent. mortgage debentures, a limited number of which they propose to issue. The directors who retire by rotation this year are the chairman and Mr. Buxton, and they offer themselves for re-election. Mr. Mottram, the audior, retires, but is eligible for re-election.

The chair was occupied by Mr. F. W. Harmer.

The **Chairman**, in moving the adoption of the report, said that though the work of the Company had given the directors a good deal of anxiety during the last three or four years, they had, happily, little cause for anxiety now. The Company had given great satisfaction to its patrons, not a single customer who had once adopted their service having given it up. They were under a great debt of obligation to Messrs. Laurence and Scott, whose plans in the main the Company had adopted.

Mr G F. Buxton seconded the motion, and the report was adopted.

The two retiring directors were re elected.

ORIENTAL TELEPHONE AND ELECTRIC COMPANY.

The annual general meeting of this Company was held on Monday at the Cannon-street Hotel, Mr. William Addison in the chair.

The **Chairman** moved the adoption of the report, which was published in our last issue, and stated that the business of the Company was generally making progress. The subsidiary company in India called for little comment. The revenues were improving, and if silver rose in value they might expect better remittances from them. He hoped the China and Japan Company would also improve now that the war was ended. Altogether, the shareholders might congratulate themselves on possessing a business which was thoroughly sound. The report was adopted.

Digitized by Google

INDO-EUROPEAN TELEGRAPH COMPANY, LIMITED.

The ordinary general meeting of this Company was held on Monday at Winchester House, Mr. J. Herbert Tritton presiding.

In moving the adoption of the report, the **Chairman** said the year showed a slight falling off as compared with 1893. The fluctuation in the message business had occurred mainly in the trade with India, and would have been greater but that it had been partially compensated for by increases under other heads. With Indian business there could not be a continually-increasing amount of traffic, such as almost invariably made itself manifest with certain other communities such as Australia. The Governments of Australasia had extended their guarantee for the loss arising from the introduction of lower tariffs for another five years. The report was adopted.

MIX AND GENEST, LIMITED, BERLIN.

A meeting of the shareholders of this Company was held last week, at which a dividend of 11 per cent. payable forthwith was declared for the year ending December 31, 1894. The gross profit amounted to 434,552 marks, which, after deducting expenses amounting to 152,391, leaves an available profit of 282,161. After writing off 48,000 on plant and tools account and 40,000 marks off patent account, which latter stands now nominally at 1s. only, and after transferring 7,000 marks to the workmen's benevolent association, a balance of 690 marks was carried forward to the new account. The board of directors state that the works have been busy since the beginning of the present year with large orders from various Governments as well as from their regular trade customers, and the prospects are very promising, as all their hands, numbering nearly 1,000, are fully employed. The Company have concentrated their various works since the beginning of January in their newly-erected large factory, the cost of which, including outfit, came to 1,100,000 marks. The building, one of the finest in the telephone trade, is fitted up with the most modern machinery and appliances, and sufficient adjoining land has been acquired for an ultimate extension when necessary.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Birkenhead.—The Corporation invite tenders by 23rd inst. for boilers, engines, dynamos, etc. Particulars are given in our advertisement columns.

Tunbridge Wells.—Tenders are invited by the Corporation for the wiring of the Municipal Buildings in accordance with the specification prepared by the electrical engineer. Copies of the specification may be obtained from Mr. W. C. Cripps, town clerk, Town Hall, Tunbridge Wells, on payment of a deposit of £1, which sum will be returned on receipt of a bona fide tender. The buildings can be inspected at any time. Tenders, endorsed "Electric Light," must be sent to the town clerk by 28th inst.

Brighton.—Notice is given that the Council of the borough will receive tenders from such persons as may be willing to enter into a contract for the supply and erection of boilers at the Corporation electricity works. The Council also want tenders for the supply and erection of arc lamps, switches, etc., and, thirdly, for the supply of indiarubber lead-covered armoured cables. Specifications can be obtained on application at the town clerk's office, Town Hall, Brighton. Tenders for the boilers are to be sent in by May 13; for the arc lamps, switches, etc, by May 27; and for the indiarubber lead-covered armoured cables by May 13.

Rangoon.—Tenders will be received by the president of the Rangoon Municipal Committee, not later than November 4, for the lighting of Rangoon by electricity. Tenders should be accompanied by detailed plans, specifications, and estimates, and must state the terms on which the installation proposed will be undertaken. All information regarding the existing system of lighting and the cost, etc., with plan of the town, can be obtained on application to Messrs. Ogilvy, Gillanders, and Co., Sun-court, 67, Cornhill, London, E.C., accompanied by a remittance of £1. 1s. Tenders are to be sent in sealed covers and endorsed "Tender for Electric Lighting, Rangoon." Mr. J. Short, Rangoon, is the secretary of the committee.

Manchester.—The Corporation invite tenders for the supply, delivery, and erection, complete, of the electric lighting machinery and installation for the efficient lighting of the new foreign animals wharf, situated at Mode Wheel. Copies of general conditions, specification, and drawing can be obtained on application to Mr. T. de Courcy Meade, city surveyor, Town Hall, Manchester, on payment of five guineas (which will be returned on receipt of a *bonâ fide* tender). Tenders, to be endorsed "Tender for Electric Lighting, etc., Foreign Animals Wharf, Mode Wheel," to be addressed to the chairman of the Markets Committee, and delivered at the city surveyor's office not later than 9 a.m. on Monday, May 13. The Corporation do not bind themselves to accept the lowest or any tender.

Shoreditch.—The Vestry invite tenders for the erection of a dust destructor, 12 furnaces, flues, boilers, and accessories, to be guaranteed capable of dealing with about 20,000 tons of refuse per annum and of producing the amount of steam stated in the specification for electric lighting and other purposes. A formal contract to be entered into under seal, with sufficient sureties, to secure such guarantee. Forms of specification and sketch plan, with further information, may be obtained from Messrs. Kincaid, Waller, and Manville, the engineers, of 29, Great George-street, Westminster, S.W., on payment of £3. 3s., which will be returned to persons tendering on a bona fide tender being received by the Vestry. Sealed tenders must be sent to the vestry clerk, endorsed "Tender for Dust Destructor, etc.," by Monday, May 20, or by such extended period as may be specially allowed to any intending contractors upon application to the engineers; and contractors, or their representatives, must attend at the Town Hall, Old-street, E.C., at 6 p.m. on the same date, when the tenders will be considered by the committee. Trade union rates of wages and hours must be observed by contractors.

BUSINESS NOTES.

Western and Brasilian Telegraph Company.—For the past week the receipts were £3,130.

Sunderland.—The Corporation have now 29 customers for the electric light, and the number is stated by Alderman Bell to be increasing daily.

Rickmansworth.—Mr. Dockree has given a notice of motion at the next meeting of the Parish Council in favour of the introduction of the electric light into Rickmansworth.

Buxton.—The Urban District Council, it appears, intend to do nothing in connection with the electric light at present, but will apply for an extension of time when the powers expire.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 28th ult. amounted to £1,121, as compared with £667 in the corresponding week of last year.

Newcastle-on-Tyne.—A new branch of manufacture has been started at the Elswick Works of Sir W. G. Armstrong, Mitchell, and Co. in the production of the Thomson-Houston dynamos.

Electro-Hygienic Company, Limited.—This Company has been registered, with a capital of £20,000, to enter into an agreement with H. C. Braun and H. C. B. Sharman, for the acquisition of certain patents, patent rights, etc., particulars of which do not transpire.

Jandus Arc Lamp and Electric Company, Limited.—This Company has been registered, with a capital of £20,000 in £10 shares, to acquire letters patent relating to improvements in electric arc lamps, and to carry on the business of an electric company in all its branches.

St. Helens.—The Gas Committee of the St. Helens Corporation have approved of plans for putting down plant at the gasworks capable of lighting the Town Hall and the Gamble Institute by electricity, and also for meeting any further immediate demands for extension of electric supply in the neighbourhood.

Cardiff.—A De Laval combined steam turbine and dynamo of 5 h.p. has been installed on the premises of the *Western Mail* by Messrs. George Thomas and Co., of Manchester, who have lent the plant for experimental purposes, Mr. W. H. Massey having introduced the machine to the notice of the owners of the journal.

City and South London Railway.—The receipts of the Company for the week ended April 28 were £900, against £901 for the corresponding week of 1894, or a decrease of £1. The total receipts for the current period of the present half-year are £16,119 against £15,514 in the corresponding period of 1894, an increase of £605.

Lamp Manufacturing Company, Limited.—This Company has been registered, with a capital of £20,000, to enter into an agreement with the Lamp Manufacturing Company, Limited, and the liquidator thereof, and to carry on business as manufacturers of and dealers in lamps of every description, as electrical engineers, etc.

Business Change.—Mr. S. Crichton Hannah, of 5, John-street, Adelphi, W.C., who has been for over 20 years designer for Messrs. B. Verity and Sons, having severed his connection with the firm, informs us that he is now in a position to supply designs and working drawings of all styles of electric fittings, ironwork, etc., to the trade.

Islington.—A meeting of the Vestry has been held, at which the Vestry Clerk read a communication from the Vestry of Southwark, enclosing copy of a resolution passed by that body, suggesting the advisability of some authority having control over gas-mains, and having the power to compel the gas companies to repair them so as to prevent escape.

Metropolitan Asylums Board.—Sir Edwin Galsworthy presided at a meeting of the Board at the County Hall on Saturday last. A letter was read from the Electrical Trades Union asking that a clause with regard to trades union working regulations might be inserted in all the managers' contracts for electrical work. This was referred to the Special Committee on Contracts.

Bournemouth.—The Lighting Committee of the Town Council have recommended that permission be not given to the placing of a lamp near the Lansdowne Baptist Church. A letter had been received from the Bournemouth Electric Supply Company, Limited, stating that there had been no change in the constitution of the company involving a transfer of the undertaking.

Hampstead.—The Lighting Committee of the Vestry have recommended that the Vestry of Islington should be informed that the Vestry agreed with the views expressed in their letter on the subject of escapes from gas-mains laid under the public streets, and that a similar representation to that of the Vestry of Islington should be

Digitized by Google

made to the Board of Trade on the subject. The recommendation was adopted by the Vestry.

Earl's Court.—The giant wheel in the exhibition grounds at Earl's Court has been completed. At night the wheel will be lighted by electricity, the plant for which has been supplied by Messrs. J. G. Statter and Co. A double line of incandescent lamps will encircle the periphery of the wheel on either side, in addition to which the cars, promenade-rooms, etc., will be brilliantly lighted by electricity.

Manchester Suburban Electric Supply, Limited.—This Company has been registered, with a capital of £25,000, to take a transfer from the Collier-Marr Telephone and Electrical Manufacturing Company, Limited, of a provisional order granted to them by the Board of Trade, and to supply electricity for any purpose whatsoever within the urban sanitary district of Moss Side, and as electrical engineers generally.

Tilbury.—The Parish Council have received a letter from the secretary of the London and India Dock Joint Committee stating they were in a position to supply the parish with the electric current for lighting purposes if by so doing they would not be infringing the rights of any other lighting company. The Clerk said he had seen Mr. Borradaile, who said the gas company had a monopoly for gas only. The matter was left over to the Lighting Committee.

Epstein Accumulators.—In addition to the central-station batteries for the Kensington and Knightsbridge Electric Lighting Company, Limited, and the Preston Electric Supply Company, Limited, the Epstein Electric Accumulator Company, Limited, have just obtained the order for two new batteries of large capacity from the Notting Hill Electric Lighting Company, Limited, to be erected at their central station, Bulmer-place, Notting Hill-gate, W.

Electric Lighting Bills.—At a sitting on Monday of the Examiner for the House of Commons, 13 Electric Lighting Bills were found to have complied with the orders of the House applying to them at this stage. The Electric Lighting Bills are for the confirmation of orders made by the Board of Trade in respect of Worthing, Winchester, Motherwell, Stirling, Alderley Edge, Leigh, Llandudno, Luton, Radcliffe, Swindon New Town, Carlisle, Pontypool, and Walthamstow.

Birmingham.—Some hitch, it is stated, has occurred with reference to the contract of Messrs. D. and G. Graham, of Glasgow, for the supply of the electric lighting plant for the new technical school in Suffolk-street. A special meeting of the sub-committee which has the matter in hand has been held, when the subject was considered, and the hope expressed on the part of the contractors and the committee that nothing would arise to prevent the work being successfully carried out.

Draycott.—The Parish Council have held a meeting at which the question of publicly lighting the streets came on for discussion, Mr. Astle remarking that he had decided to place a 16-c.p. electric light on the Station-road and not charge for it, just to give the people a chance of seeing the effect. He had had an expert's opinion on the question of laying down the current from Wilne to Draycott, but the expert had given it as his opinion that it would entail too much expense, so that would have to be abandoned.

Oldham.—The Electric Lighting Committee have reported to the Town Council that Prof. Kennedy has estimated the additional cost of extending the electric light supply at £10,000 Alderman Smith said the original estimate was for £27,000, of which £25,550 had been expended. There had been so many applications for the electric light that the Corporation had not the power required for the work. It had become necessary to extend the cables to Werneth Park and along Huddersfield-road in an easterly direction.

Rothesay.—A special meeting of the Harbour Trust has been held, at which a minute was submitted recommending that the pier be lit with electric light at an estimated cost of over £1,000. It was stated that the steamboat owners would oppose the scheme unless the esplanade and other parts of the town were embraced in it. The intention is to erect a 30-h.p. turbine wheel, driven by water from Lochfad, to generate the electricity. It is calculated that the new lighting will cost annually £280. The committee having the matter in hand were asked to deal with some objections, and to report early.

Twickenham.—The District Council have held a meeting at which two tenders were received for the erection of seven fire-alarm street posts, and electric call wires to 15 firemen's houses and the police station. Messrs. Harrison and Cole's tender of overhead wires was £217. 11s., with a reduction of £25 if wall boxes were used instead of posts, or with underground wires £766. 5s. Mr. Stewart's tender was £298. 12s. 6d. for overhead wires, or £1 184. 12s. 6d. for underground wires. It was decided to have overhead wires, but the final selection *re* tender was referred to the Works Committee and the surveyor.

General Traction Company, Limited.—This Company has been registered, with a capital of £50.000, to adopt and carry into effect an agreement expressed to be made between the Electric and General Contract Corporation, Limited, of the one part and this Company of the other part, and to enter into or acquire and carry out contracts or concessions or other grants in any part of the world for constructing, purchasing, or working railways, tramways, telegraphs, telephones, electric and other lighting works, electric, hydraulic, or other works, and for the equipment of any such undertakings or works with electric or other plant, stock, or apparatus.

Maidstone.—A committee of the Urban District Council have reported that they received an offer from Mr. Thomas King, in which he proposed to form a local company to take a transfer of the provisional order obtained by the Council. Mr. King submitted a draft agreement and deed of transfer, which had been considered by the committee, and certain alterations and additions would be suggested to Mr. King. The committee will shortly present a further report to the Council embodying Mr. King's proposals and a recommendation from the committee. The report was adopted without comment on the motion of Alderman Ellis.

Aberdeen.—The Gas Committee of Aberdeen Town Council have held a meeting at which the Electric Lighting Sub-Committee reported with reference to the supply of current for electric motors. They recommended that the supply be given during the day at 4d. per unit, and this was agreed to by six votes to two. It was resolved to recommend that the Council continue to rent the shop in Union-buildings at present used as a gas-stove depôt, and which is to be reconstructed and enlarged. The rent will be £100, but the electric lighting department will pay £20 of this sum, and one of the windows will be devoted to the exhibition of electric motors in action.

Telephony in Warwickshire.—A meeting of the Warwickshire Standing Committee has been held, at which Alderman Stanton enquired how it was that only one police station was to be connected with the telephone. It was widely thought to be very desirable that there should be a complete telephonic system throughout the county for police stations. Councillor Vero said Mr. Fielding Johnson had had this matter in hand, but unfortunately he had not been able to get the telephone company to give such terms and facilities as they felt they were entitled to have. Under the circumstances, it was not thought wise to connect all the stations in the county.

Copper.—There is something rather puzzling about the statistics of copper, says the *Financial News*. During the past month the stocks in England and France and afloat have increased by 904 tons, and now amount to 54 239 tons; but, although consumption failed to keep up with the supplies in April, the price of Chili bars has risen £1. 12s 6d. per ton since March 31. It is true that at £40. 17s. 6d. a ton copper is not at an extravagant figure; but how little statistics can be relied on in estimating the course of prices appears from the fact that on May 31, when the visible supply was nearly 7,000 tons smaller than it is now, copper was only £38. 17s. 6d., or £2 a ton cheaper than it is to-day.

Coventry.—At the last meeting of the Town Council, Mr. Morton questioned the chairman of the Electric Light Committee as to a statement made in a pamphlet which the Corporation had issued, which declared that the electric light at 6d. per Board of Trade unit was equal to gas at 4s. per 1,000ft. He thought there must be some mistake, and people were holding back from ordering the light because they felt it was going to be more expensive than gas. He asked the chairman if he could guarantee the statement as to comparative cost. Alderman Hill replied that his authority was the electrical engineer to the Corporation. The general district rate has been mortgaged for £5,000 at 3¼ per cent. for electric light expenditure.

Planet Electrical Engineering Company.—Judgment has been given by Mr. Justice Stirling in the action Wallace and others against the above Company. Plaintiffs are holders of £2,500 debentures of the Company, issued in December, 1893, and as no interest had been paid the principal money became due in default, and the usual debenture-holders' action was brought. The Company in February last passed a resolution for winding up, and this motion for judgment in the action was brought on by consent. His Lordship made an order declaring the debenture-holders entitled to a charge on all the Company's property, directing the usual enquiry, and giving liberty to apply in chambers as to sale.

Huddersfield.—The Corporation accounts for the past year show the following results: the sum borrowed amounted to £44,000, and there is still £6,000 sanctioned, but not borrowed. The total expenditure was £46.041, being £2 041 in excess of the amount raised by loans. The cost for the year for the generation and distribution of current, including royalties, rents and taxes, and management expenses was £2,184, and the receipts £3,580, leaving a balance carried to net revenue account of £1,376, which account shows a deficiency at the end of the year of £2,065. The quantity of units produced was 265,146, making the cost per unit generated to be 1·98d. There were 156,169 units sold, the cost per unit sold being 3·16d.

Rotherham.—Messrs John Dewhurst and Son, electrical and mechanical engineers, of Sheffield, have just completed an electric light plant at the works of Messrs. Baines and Co., brassfounders, Rotherham. The installation consists of a 10-unit "Hallamshire" dynamo, which is driven by the works engine, and 112 16-c.p. incandescent lamps in the turning shops. The 16-c.p. lamps, of which there is one over each lathe, are fitted with raising and lowering gear, enabling the workmen to adjust the light to the best advantage for the work they are doing. Each lamp is fitted with a switch. The yard and outbuildings are efficiently lighted by lamps of 32, 50 and 100 c.p. The installation is working very smoothly, and the proprietors speak highly of it.

York.—A special meeting of the York City Council, held on Monday, received the report of a committee making, among others, recommendations for the adoption of the scheme of the Electric Construction Company, of Wolverhampton, and the acceptance of the tender for the plant and fittings for £10,865, subject to powers being granted for a loan for the execution of the works

Digitized by Google

Mr. Creer, the city surveyor, had reported to the committee that the low-tension three-wire system would be best for York. Eventually the committee's report was referred back with a request that the total cost of the entire plant, buildings, and land be given, and also a report upon the various works visited, and asking them to request Prof. Kennedy definitely whether or not he agreed with the advice given to the Council by Mr. Creer.

Crompton Electric Supply Company of Australia.—In the action of Whiffen and others *v.* the Crompton Electric Supply Company of Australia, Limited, and others, Mr. Butcher asked on Friday for the appointment of the secretary of the Company as receiver and manager. There were three series of debentures issued. Plaintiffs were holders in all of them. The interest was in arrear, and this step was taken in order to protect the property and assets of the Company, the whole of which were in Australia. The secretary was resident in England, but plaintiffs were ready to undertake for his receipts. The application was granted, but the judge reserved for chambers the question of appointing a deputy-receiver resident in Australia, and giving him power to make any necessary advances for carrying on the undertaking.

Ealing.—The Urban District Council have held a meeting, at which a letter was read from Messrs. Bramwell and Harris accepting the terms on which the Council had appointed them as consulting engineers of the electric lighting works. A communication was read from Mr. Strickland with reference to an account for the consumption of current. He questioned whether the meter was accurate and whether the amount of current charged for had actually been used. An opinion was expressed that as the accuracy of the meter was doubted it should be tested, but that in order to guard against any frivolous complaints of incorrectness in meters or in the amount of current used, the Electric Lighting Committee should be requested to suggest a charge to be imposed in cases in which a testing of the meter on the complaint of the consumer had resulted in the meter being found correct. The matter was referred to the Electric Lighting Committee accordingly.

Theft.—Horace Richard Eve, 21, a clerk, was charged on Friday at the Mansion House before Sir G. Tyler with stealing £237. 10s. from the Brush Electrical Engineering Company, in Queen Victoria-street. The prisoner had been about six months in the company's employment, and on the day before Good Friday he was the last to leave the premises. In the Easter holidays some workmen were engaged to paint the offices. On the return of the staff on Easter Tuesday it was found that a cash-box had been opened, and £237. 10s. abstracted. Subsequently the prisoner disappeared, and a rumour that he had been murdered was circulated. He was, however, traced to Aberdeen by the police, and arrested. He now pleaded guilty, and it was stated that his defalcations were caused by betting, gambling, and dissipation. Only £20 was found on him when arrested. The police stated that he had been previously convicted. He was committed for trial.

Kingston (Surrey).—The Lighting and Market Committee of the Town Council have reported that they informed the Street Improvement Sub-Committee that they were prepared to arrange for electric fittings to the labouring-class dwellings in course of erection in Pheasant-lane, and suggested that the current should be charged for by way of a fixed sum to be paid with the rent, the difference to be accounted for quarterly. The balance-sheet of the committee showed a debit balance of £3. 13s. 4d. Their estimated expenditure for the half-year was £3,196. 9s., including £1,050. 10s. to the gas company for street and Canbury Gardens lighting, £686. 17s. 5d. repayment of principal and interest on electric lighting loans, £500 for fuel, and £620 salary and wages; £450 was estimated as the income from consumers of electric light, leaving £2,746 to be raised from the rate. This sum included the cost of the street arc lights. The committee recommended a rate of 5½d. in the £, which will produce £2,750. The minutes were approved.

Hull.—We mentioned in our last issue that an enquiry was to be held by Colonel Charles Henry Luard, R.E., in respect to the proposed borrowing by the Hull Corporation of £2,800 for electric lighting purposes. There were present at the enquiry Mr. G. Duncan (town clerk's department), Mr. A. E. White (borough engineer), Councillor J. Shaw, Mr. Gibbins (electrical engineer), Mr. Milner (borough treasurer), and Mr. Redfern (borough accountant). Mr. Gibbins explained that the amount of £2,800 was to meet the demand of the public—for electric light—on the plant. The electric station had been in successful operation for 18 months, and they now asked for the loan for the purpose of meeting the demand of the town for electricity. They could at present supply 14,000 8-c.p. lamps, and if the loan were granted it would increase the output to 21,000 8-c.p. Mr. Milner said that the working of the electric lighting station had been very successful since its inception in January, 1893 At the end of the last financial year they had a balance in hand of £996, after meeting the demand for the sinking fund and interest. Colonel Luard then visited the electric station.

Aberystwith.—The Public Lights Committee of the Town Council have recommended that the Council should enter into a temporary arrangement with the Bourne and Grant Electrical Company for the running of the electric light for the public lamps pending the testing of the same, and that the Council offer to pay for the same at a rate not exceeding the rate provided by the existing agreement, but in the event of the light not answering the required test that the amount payable be in proportion to the candle-power as certified on behalf of the Council at the rate of £20 per annum per lamp of 2,000 c.p., the arrangement to be without prejudice to the rights or position of the Council, and to be terminated forthwith upon the result of the testing being communicated to the company. The committee likewise recommended that the lighting of the public streets by gas should be discontinued where other lamps exist. Mr. Breech, the electrician of the company, attended the meeting, and was requested to call the attention of the company to the absolute necessity of their immediately laying their second cable, and of completing the arc light at the town clock without further delay. The recommendations were adopted.

"D.P." Accumulators.—Up to the present this accumulator has been exploited by Messrs. Drake and Gorham, who appointed Messrs. Johnson and Phillips sole manufacturers for the United Kingdom. It has now been decided to form a separate company, known as the "D.P." Battery Company, who will take over the whole of the battery business from May 1. The London branch of the company, to which all enquiries should be addressed, will be situated at 66, Victoria-street, Westminster, S.W., the works being at Old Charlton, as at present. The company will retain the services of Messrs. Drake and Gorham, who, it will be remembered, were formerly managing-engineer and works manager of the Electrical Power Storage Company, and were afterwards connected with the Elwell-Parker battery, so that they may be said to have had an exceptional experience in battery work. The works will be under the able management of Mr. Claude Johnson, of Messrs. Johnson and Phillips, and considerable additions to the existing large plant are meditated. It is hoped that this consolidation of interests, trading under an independent title, which is less likely to arouse any possible jealousy on the part of the trade, will materially increase the business, which has already assumed very large proportions.

Derby.—The Town Council on Wednesday passed a resolution directing application to be made to the Local Government Board for sanction to the borrowing of £5,000 for electric lighting purposes. This sum was granted at the meeting of the Council held on March 6 last, and of this sum £3,134 has now been expended. Tenders have been invited for three mild-steel boilers, and the tender of Mr. E. Danks, of Oldbury Boiler Works (£1,570), has been accepted. The Electric Lighting Committee have engaged the following additional staff, which they consider sufficient to enable them to work the station without outside assistance: three arc light trimmers, 30s., 24s. 6d., 24s. 6d. per week; vulcanised jointer, £2 per week; jointer's assistant, etc., 24s. 6d. per week; carpenter, 32s. per week; storekeeper, 24s. 6d. per week. The machinery, etc., at the station has been insured for £24,250. A sum of £400 has been retained out of the moneys due to Messrs. Siemens Bros. as a security for the efficiency of the arc lamps for 12 months. Messrs. Siemens Bros. have been relieved from their responsibility of reinstating the roads upon a deduction being made from the moneys due to them of £100. The borough surveyor will now complete the reinstatement of the roads.

Acton.—The District Council have held a meeting, at which Messrs. New and Mayne were reported to have written accepting the insertion of the suggested sliding scale in the agreement for the lease of the provisional order, and asking that as they had met the Board in this matter the fact might be remembered in connection with any small points which might arise. Mr. Buxton moved: "That the resolution passed at the Council meeting of March 19, empowering the Council to sell the provisional order for lighting the parish of Acton with electricity to Messrs. New and Mayne be rescinded." This was seconded by Mr. Poulton. Mr. Grant moved that the proposition of Mr. Buxton be amended by the substitution of the words "not carried out until the opinion of the parochial electors of Acton has been ascertained," for the word "rescinded." He added that the Council might afterwards decide how to ascertain the feelings of the ratepayers. Mr. Lewsey seconded this. After further discussion the amendment was carried unanimously, and Messrs. Buxton and Rome were asked to prepare a statement as to what was proposed to be done in the matter of the electric lighting of the district, with a view to its being submitted to the electors with a request that they would express their opinion for or against the proposal to sell the provisional order to a private company.

Tunbridge Wells.—Current is to be supplied to the public at Tunbridge Wells at a charge of 6d. per unit. Petitions are being received from various suburban and other centres asking that the original electric light scheme may be extended. The Electric Lighting Committee of the Town Council report that they are unable to grant any of these applications, as the Council have entered into contracts which will absorb the whole of the money for which they have obtained borrowing powers. The committee are of opinion that it is desirable to extend the electric lighting works wherever there is a prospect of current being taken by a sufficient number of consumers to make it remunerative. The total amount of Mr. Preece's original estimate was £25,000, of which £13,000 was the estimated cost of lighting the compulsory area. As, however, many ratepayers beyond the compulsory area are willing and anxious to use the light, the committee are of opinion that the time has arrived when the Council should place themselves in a position to undertake extensions. They therefore recommend the Council to borrow the balance of Mr. Preece's original estimate—£12,000; to instruct the town clerk to apply to the Local Government Board for sanction to the necessary loan; and to authorise the Mayor to affix the seal to all documents necessary for that purpose.

Plymouth.—The Western District Ratepayers' Association have held a meeting, at which Dr. Square said Plymouth was dreadfully behind in the matter of lighting, and it was anything but

Digitized by Google

satisfactory to think that such little places as Okehampton, St. Austell, and Taunton had got the electric light, while the big metropolis of the West was without it. Corporations generally were giving their attention to this matter. It had been proved that the ratepayers financially were very much better off by having the electric light, and the Plymouth ratepayers ought to be the owners of the electric light, and be able to make money out of it. Wherever the electric light had been adopted for public purposes the gas companies had done better, so that they were not trying to injure the gas company. At present Plymouth paid £4,000 a year to the gas company. The gas was very cheap, but he rather fancied he had seen gas of a better quality. The method generally adopted by corporations was to get a financier to float a company for three years, and at the end of that time, if it were a success, the Corporation took it over. Plymouth ought not to be behind-hand in this matter, and he moved that an installation of the electric light be adopted. It was generally felt that the question was of sufficient importance for a whole meeting to be devoted to it, and the matter was referred to the committee for their consideration.

Dover.—The inauguration of the electric light at Dover may now be said to have been fairly accomplished. The works cover an area of 10,000ft., with a height of 30ft. to the eaves. The rooms comprise engine and machine room, 100ft. by 30ft.; boiler-room 100ft. by 42ft., giving ample space for seven sets of engines and seven boilers; testing-rooms, secretary's offices, Board-room, stores, and lavatory. Besides these there are underground passages in which the circulating water-pipes and exhaust-pipes are placed running from the works to the river, about 100 yards distant. At present the plant includes two Babcock and Wilcox boilers of 200 h.p. each, working to a pressure of 150lb. each. In the boiler-room there is space for half-a-dozen boilers altogether. There will ultimately be four 100-kilowatt machines, one 75 and one 50 kilowatt machine. The work is estimated to cost about £40,000. and it is stated that there is room to extend the works to twice their size if required. Half the 21 public lamps at present supplied with the current are kept going from sunset to sunrise—six on the sea-front and four between there and the Market-square—and the remaining half are supplied from sunset till midnight. For this the Corporation pay the Dover company the sum of £650 annually, payable quarterly. For additional arc lamps erected the Corporation will have to pay £23 per annum for those supplied from sunset to midnight, and £30 for those supplied from sunset to sunrise. The price of current is 8d. per Board of Trade unit, with a minimum charge of 13s. 4d. per quarter.

Smoke Consumption.—In the Court of Bankruptcy the affairs of Mr. Samuel Elliott have been before Mr. Registrar Hope. The bankrupt, in reply to the official receiver, stated that he was a manufacturer of joinery and mouldings, carrying on business at the Albert Works, Newbury, and also having offices in the City. He started originally as a builder and contractor about 38 years ago, but the building trade became so bad that he was advised to change his business and go into the moulding trade. That was about six years since. The building business had not been a success, but the moulding and joinery business had been fairly successful. In 1889 he began developing patents. He invented a smoke washer, and exploited the patent on his own account. As a smoke washer the patent was eminently successful, but it was not a success financially. He had borrowed money in order to develop the patent, and had lost or sunk about £40,000 in connection with it. The bulk of his liabilities were in respect of the smoke patent, and his accounts showed liabilities expected to rank about £65,000, and assets £8,200. He had been in financial difficulties for some years, and he considered that about 500 executions had been levied on his property during the last five years, involving the payment of costs to the amount of something like £1,000 a year. For 10 years his banking account had been overdrawn, and since he had started the smoke patents his financial position had become more and more embarrassed. He had entered into a contract for the sale of the patents for £200,000, subject to a company being floated. The official receiver remarked that the company had all ended in smoke. The bankrupt admitted it, and said that he had charged the smoke patents for about £47,000. The patents were entirely a speculation outside his business and had caused his failure. Mr. Street appeared for the trustee, and Mr. Rolland for the bankrupt. Further accounts being required, the examination was adjourned to May 23.

Sandylands.—An adjourned annual meeting of the Sandylands ratepayers has been held for the purpose of considering the lighting question. Mr. J. J. Arnold presided. The notice convening the meeting having been read, the Chairman called upon the secretary to state what had been done by the inspectors and committee with respect to the law case against the Morecambe Electric Light and Power Company. The Secretary explained that the inspectors and committee had met the chairman and secretary of the electric light company, and an agreement was drawn up to the effect that the action should be withdrawn, each party paying their own costs, and that the inspectors have a right to use the lamps and lamp-posts free of charge until defendants are in a position to supply the electric light according to agreement; all cables, etc., to remain; also the original agreement for three years' lighting on the same terms, to commence after three months' notice has been given by the company. The Chairman said the inspectors required £50, in addition to the £50 voted at the last meeting, for lighting purposes. The expenses up to the present amounted to about £25, which included about £20 for solicitors' expenses with the electric light company. The average cost of supplying the 15 lights amounted to about £30 per year, and therefore an additional sum was required. Mr. Bottomley, replying to a ratepayer, said that so long as the electric light company was in operation the contract would exist. As soon as the new station was finished it would be to their advantage to light up the district. The company had already spent nearly £300 on the Sandylands contract. In answer to Mr. King, the Chairman replied that the plant already laid down belonged to the lighting authority until the company were ready to lay down electricity. Mr. Lambert said it was at the ratepayers' discretion as to whether the district was lighted with oil, gas, or electricity. Mr. King moved that the front be left as it is at the present until the latter part of the year, and this was carried.

Worcester.—The Town Council have held a meeting, at which the report of the Finance Committee was brought up, including the city budget for the ensuing year. The report was presented by Mr. Millington, who, in coming to the electricity department, said that many members of the Council had been anticipating that some estimate should be laid before them, and the committee had been consulted on the subject, but they thought that, as the business had been in existence for but a short time, it was unfair to ask them to give an estimate of the probable receipts and expenditure on the first year's existence. Mr. Millington offered an estimate, as his own statement, and for which the Electricity Committee were in no way responsible. For the information of the Council he might state that the revenue for the six months ending March 25 last amounted to £1,381. 19s. 7d., while the working expenses for the same period were £1,399. 0s. 5d., leaving a debit balance of £17. 0s. 10d., which did not include any provision for interest and repayment of capital. He would calculate interest on £50,000, although the Council had sanctioned £60,000. That made a sum of £2,996 for interest and redemption; salaries and wages, £1,100; coal, oil, repairs, tools, etc., £1,000. They had then to provide £5,096 in the 12 months. On the other side, what would be their possible receipts? They had 8,000 8-c.p. lamps, which at 8s. per annum would yield £3,200. By street-lighting £600, water pumping £450 (which item was, however, in dispute), and £200 by rent of mills. cottages, meters, etc. That made £4,450. It was only fair to ask what they would be doing in the next half-year? Supposing 2,000 more lamps were installed it would yield another £800, making the total receipts £5,250. Mr. Millington gave particulars of the capital expenditure on the electric lighting scheme up to April this year. Having regard to the question of which Mr. Rushton had given notice to ask as to the actual sum, out of the £60,000 voted by the Council for electricity works, spent up to the present time, Mr. Millington explained that actual payments and liabilities incurred, but not yet paid, amounted to £57,083. 6s. 1d. That left £2,916. 13s. 11d. out of the £60,000. In that he had not included the item of £1,068 claimed by the contractor as to the breaking of the water-dam, a claim in respect of which the Council did not admit their liability.

Hanley.—The Town Council held a meeting on Tuesday, when the Electric Lighting Sub-Committee submitted a report which, in accordance with the instructions of the Council, the borough engineer (Mr. Lobley) and the electrical engineer (Mr. Cottam) had drawn up for the further extension of the electricity works and mains. The extension scheme submitted includes provision for low-tension distributing mains for private supply of energy in the following streets: parts of Market-street, Bath-street, Hope-street, Etruria-road, Clough-street, Trinity-street, Piccadilly, Pall-mall, Stafford-street, Tontine-street, Charles-street, Birch-terrace, Jasper-street, Regent-road, Bethesda street, Broad-street, Snow-hill, and Stoke-road. To supply the above, high-tension mains are requisite in Market-street, Hope-street, Clough street, Bethesda-street, Cannon-street, George-street, Broad-street, Snow-hill, Stoke-road, and across the park by way of Wellesley-street, and Matlock-street. A second circuit of 30 arc lamps requires arc light cables to be laid in Hope-street, New Hall-street, Pall-mall, Albion-street, and Regent-road, also in Broad-street, Snow-hill, Stoke-road, Park-avenue, Victoria-road, Cleveland-road, and Outer Circle-road. The demand for current in the centre of the town necessitates the drawing in of a new high-tension cable of double the existing capacity between the works and the Town Hall, the existing cable being utilised in the other streets mentioned. The estimate for the above cables, including laying, is £5,508. The extensions of the mains require the provision of 16 sub-stations, 20 transformers, 25 junction-boxes of various kinds, and 30 arc lamps and posts. The estimates for these, including the extensions at the generating station, amount to £5,900. The street-lighting of the park roads, not provided for by arc lamps, includes 30 small lamps complete, and portions of the town where mains are being laid are provided for by fitting up 60 small lamps for electric lighting. These items, including the extension of the main switchboard arrangements, and a sum of £322 for excavation, formation of ground and railings at the generating station, are estimated to cost £1,242. In consequence of the increasing demand for electrical energy within the compulsory area, considerable extensions have been made to the machinery, mains, sub-stations, and transformers, amounting to £2,650; and the buildings, furniture, excavating, drainage, and formation of ground, amounting to £2,000. These items, together with a sum of £200 for clerk of works, printing, and stationery, not included in the original application, amount to £4,850. The first application on account of meters and stores, including fittings on consumers' premises for which rent is payable, was for £1,600. This sum has been exceeded by £250. A further sum of £1,250 is estimated to be required for the same purpose, which, added to the overdraft of £250, makes an estimate of £1,500. Total estimates for extensions £19,000, or including a sum of £1,000 for contingencies, special regard being given to the laying of mains to be provided to manufacturers to supply energy for

Digitized by Google

motive power, £20,000. The following is given as a summary of the electric lighting scheme: first application, £21,000; second application for meters, etc., £1,000; third application for new steam alternator, £5 000; and present estimate, £20,000—making a total of £47 000. The committee recommended that application should be made to the Local Government Board for sanction to borrow the further £20,000 required, repayable in 25 years. The recommendations were thereupon adopted.

PROVISIONAL PATENTS, 1895.

April 22.

7966. **Portable electric apparatus.** Willard Elbridge Dow, 19, Southampton-buildings, Chancery-lane, London.

7989. **Improvements in electrically-driven wool-shearing or hair-clipping machines.** Harry William Charles Cox and Gershon Bowmar, 1, Queen Victoria-street, London.

7990. **Improvements in telegraphy and apparatus therefor.** Frederick Herbert William Higgins, 24, Southampton-buildings, Chancery-lane, London.

April 23.

8011. **Improvements in the electrodes or plates of electric storage batteries.** Georg Hübener, 70, Market-street, Manchester. (Complete specification.)

8026. **Improvements in electric railway systems.** James Michael Faulkner, 46, Lincoln's-inn-fields, London. (Complete specification.)

8037. **Improvements relating to electric telegraphs.** Alexander Muirhead, 124, Chancery-lane, London.

8049. **Improvements in or relating to electric alarm clocks.** William Phillips Thompson, 6, Lord street, Liverpool. (Henry Watson Knapp and Lawrence Edwin Gerrety, United States.) (Complete specification.)

8072. **Improvements in or relating to phonographs** Eduard Würl and Adolf Novotny, 323, High Holborn, London.

8081. **Improvements in the active material for secondary and primary batteries.** Alexander Schanschieff, 77, Chancery-lane, London.

April 24.

8135. **An improved electric light cask searcher and probe.** Frederic Hughes, 20, Paget-road, West Dulwich, London.

8139. **Improvements in lenses for search-light projectors.** Edward James Paterson and Claude William Hill, European Works, Pownall-road, Dalston, London.

8147. **Combined trolley and accumulator system for driving electric cars.** Theodor Nees, 323, High Holborn, London. (Complete specification.)

8161. **Improvements in electric igniting apparatus suitable for lighting tobacco-pipes and cigars.** Friedrich Wilhelm Schindler, 433, Strand, London.

April 25.

8167. **System of electro-calorigen rheostatic chain.** Armand Labre and Auguste Coussinet, jun., 77, Rue Denfert-Rocherau, Paris. (Complete specification.)

8172. **Belting for machine guns, dynamo, engine, and other purposes.** Richard Douglas Bailey, 34, Edith-grove, Fulham, London.

8186. **Improvements in electric locks.** Alfred Harvey, 128, Colmore-row, Birmingham. (Samuel Bash, South America.)

8188. **Improvements in ceiling roses and lampholders for electric lighting.** John Arthur Hirst, 8, Quality-court, Chancery-lane, London.

8195. **Improvements in cycle, electric, house, table, and other bells and gongs.** Orlando Hanks, 65, Mildmay-park, Islington, London.

8210. **A method of and means for increasing the directive force of magnetic needles.** John Sacheverell Gisborne, 19, Southampton-buildings, Chancery-lane, London.

8222. **Improvements in telephonic systems and apparatus.** John Edward Kingsbury, 24, Southampton-buildings, Chancery-lane, London. (The Western Electric Company, United States.)

8226. **Improvements in and relating to electric batteries.** Johannes von der Poppenburg, 97, Newgate-street, London. (Complete specification.)

April 26.

8253. **Electrical appliance to give signalmen control over drivers during foggy weather.** Thomas Cooper, 29, Mount-pleasant, Rycroft, Walsall.

8306. **Improvements in or connected with electric batteries.** Charles Percy Shrewsbury, Frank Laurence Marshall, John Cooper, and John Laskey Dobell, 57, Chancery-lane, London.

April 27.

8373. **Improvements in conductors for coupling cells of voltaic batteries.** William Stepney Rawson, 28, Southampton-buildings, Chancery-lane, London.

8385. **An improved wire gauze brush for dynamos and motors.** Arthur Burgess Soar and Edwin William Collier, 8, Phipp-street, London.

8392. **An improved system of lighting and heating railway vehicles by electricity.** Morris Moskowits, Leon Daniel Adler, Abraham Sanford Adler, and Theodore Walter Myers, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

8393. **Improvements in and relating to the electric lighting of railway vehicles.** Morris Moskowitz, Leon Daniel Adler, Abraham Sanford Adler, and Theodore Walter Myers, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

8394. **Improvements in means for equalising the electromotive force of dynamos.** Morris Moskowitz, Leon Daniel Adler, Abraham Sanford Adler, and Theodore Walter Myers, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

SPECIFICATIONS PUBLISHED.

1893.

12662. **Electrolysis.** Andreoli. (Second edition.)

1894.

6323. **Alternating-current indicating apparatus.** Mordey.

6661. **Electric switches.** Rorke.

6850. **Electric lamp protector.** Ungley.

7176. **Telephonic systems.** Carbonnelle.

7477. **Vulcanising electric conductors.** Edmunds.

10132. **Electrical instruments.** Edmondson.

10425. **Electrical transformers.** Kingdon.

15414. **Telephone systems.** Warrell.

22986. **Primary batteries.** Hubbell.

1895.

NOTES.

Wiring-In.—In connection with the Chitral expedition it is reported that the tribesmen in the Kutino district have been carrying off the telegraph wires.

Northern Society of Electrical Engineers.—Mr. J. C. Howell will read a paper before this society on Monday next on "The Uses of Accumulators."

Institution of Electrical Engineers.—A students' meeting will be held in the library of the Institution on Friday next, 17th inst., when a paper will be read on "Aluminium," by Mr. Gerald C. Allingham.

The China-Burmese Telegraph.—The new telegraph line in Upper Burma is now open right through to Pekin and Hong-Kong. India has thus secured direct communication with China *vid* Bhamo and Momein (Teng Yuah).

New Use for an Electric Railway. — Tommy Burns, the diver, has been using the Liverpool Electric Railway for the purpose of climbing on to the roof of a moving carriage and diving therefrom into a dock—a drop of 100ft.

The New Telegraph Line in the Shan Country.—The survey for the telegraph line from the Southern Shan country to the borders of the buffer State on the Mekong river has been completed. The wire can be put up without much difficulty.

Russian Electricians in England.—A party of Russian engineers, accompanied by M. Alphonse de Stchawinski, editor of the *Gazeta Elektrika*, St. Petersburg, have visited Brighton and inspected the works of the Rottingdean Electric Railway.

Telegraphy by Induction.—An address on this subject is to be delivered by Mr. W. H. Preece to a special meeting of the London Chamber of Commerce, which will be held in the hall of the Carpenters' Company, London-wall, on Thursday, the 23rd inst., at 2.30 p.m.

Application of the Electric Arc.—The discussion on Mr. Henry Foster's paper on "The Application of the Electric Arc to Machinery, Boiler Repairs, etc.," will be concluded at the meeting of the North-East Coast Institution of Engineers and Shipbuilders to be held at Newcastle-on-Tyne on Tuesday, the 14th inst.

Cantor Lectures.—Mr. James Douglas will on Monday evening next deliver the fourth lecture of his series on "Recent American Methods and Appliances employed in the Metallurgy of Copper, Lead, Gold, and Silver," the subject being "Absorption of the Precious Metals to, and their Separation from, Copper and Lead."

Trolley Car Accidents.—A cablegram from New York states that the Brooklyn grand jury have indicted the managers of the Brooklyn Heights Railway Company for the recent deaths caused by the trolley cars on their lines. Altogether 107 people have been killed and 450 injured by the trolley cars in Brooklyn since they first came into use.

Telephony.—A new and well-written series of articles, entitled "Practical Telephony," is now appearing in the columns of our penny contemporary, *Electricity*. The series is being written by Messrs. James Bell, A.I.E.E., and S. Wilson, and should interest a large number of readers, especially in view of the enquiry now being held by the Government.

Fluorescence of Solutions.—Mr. O. Knoblauch, in *Wiedemann's Annalen*, shows that there is a constant ratio between the intensity of the fluorescence and the existing light, even when the intensity of the latter is altered in the ratio of 1 to 6,400. The author proves experimentally and theoretically that the effect upon the various fluorescent bodies of varying the solvent is very different.

Electrically-Propelled Vehicles.—Mr. Naoroji has asked, in the House of Commons, whether the President of the Board of Trade proposed to take steps for allowing vehicles propelled by stored electricity or petroleum, if unobjectionable to the public, to be freely used in this country. Mr. Shaw Lefevre stated that he was about to introduce a Bill upon this subject which he hoped would meet the views of the hon. member.

Royal Institution.—At the general monthly meeting of the members of the Royal Institution on Monday, Sir James Crichton-Browne presiding, the following were elected members: Mr. Henry Irving, Mr. Henry Perigal, Mrs. Slingsby Tanner, Mr. Ernest H. Fry, Mr. Thomas Muir, Mr. Harold Smith, and Mr. W. S. Smith. The special thanks of the members were given to Mr. George Matthey for his donation of £50 to the fund for the promotion of experimental research at low temperature.

Royal Meteorological Society.—At the ordinary meeting of the society, to be held by permission of the council of the Surveyors' Institution at 12, Great George-street, Westminster, on Wednesday, the 15th instant, at 7.30 p.m., the following papers will be read: "The November Floods of 1894 in the Thames Valley," by Messrs. G. J. Symons, F.R.S., and G. Chatterton, M.A., M.I.C.E., and "Barometrical Changes preceding and accompanying the Heavy Rainfall of November, 1894," by Mr. F. J. Brodie, F.R.Met.Soc.

Papers.—The last meeting of the present session of the Liverpool section of the Society of Chemical Industry was held last week at University College, when Dr. Hurter read a paper on "The Efficiency of Electrolytic Apparatus."—A meeting of the Property Owners' Association has been held at Patricroft, Eccles, when a lecture on "Gas *v.* Electric Light" was delivered by Mr. William Broughton. He did not favour the local introduction of the electric light. The matter has now been taken up in the correspondence columns of the local paper by Mr. Geo. R. Peers, A.I.E.E., and others.

Unipolar Induction.—Mr. Ernst Lecher in *Wiedemann's Annalen* discusses the different aspects of the question whether, when a cylindrical magnet rotates about its axis, the lines of force due to it are stationary or rotate with the magnet. The former was Faraday's original view, the latter has been maintained by Tolver Preston and others. After showing that all the experiments hitherto quoted as decisive one way or the other may be equally well interpreted on either assumption, he describes some test experiments which show that the lines of force stand still while the magnet rotates.

The Gmunden Electric Tramway.—In Austria-Hungary there has not been much progress made in connection with electric traction, but a line at Gmünden, a health resort on the lake of Traun, which has been completed, is interesting. It is short, being only about a mile and a half in length, but the gradients are very heavy, being as great as 9½ per cent., while the line is constantly going round curves, the smallest radius being 40 metres. The electrical work was carried out by Messrs. Egger and Co., of Vienna, the whole line being completed in four months. It is a single track, with a turn-out about midway. The overhead conductor system is employed, the return being by the rails.

Digitized by Google

Cable Schemes.—Mr. Sydney Buxton (Under-Secretary for the Colonies) stated, in the House of Commons on Monday, in answer to Sir George Baden-Powell, that her Majesty's Government had not received any request from or through the Government of Canada to call a conference of the colonies interested with a view to arranging the details of the laying and maintaining a cable across the Pacific Ocean between Canada and Australasia. Mr. Arnold Morley, in reply to Mr. Henniker Heaton, said that about four years ago a request was made that a telegraph cable should be laid to the island of Sark, but as the estimate of revenue fell far short of the estimate of expenditure, the Treasury did not see their way to sanction the extension.

A Cock-and-Bull Story.—The following item is appearing in the provincial newspapers: "An interesting exhibition of a new device designed to prevent collisions at sea was recently given by Mr. James P. O'Brien between the Battery and Station Island, off New York. About 50 capitalists and electricians witnessed the force from electro-magnetic coils stationed on the tug 'Wild Hawk' influence a new chemically-prepared compass, causing the latter to ring bells instantaneously. The compass was placed at St. George and influenced as far as six miles on the water. The tests were a complete success. A syndicate of wealthy shipping men ordered 20 outfits for ocean travel. If successful for six months, Mr. O'Brien is to receive £100,000 for the patents."

Light Railways in Ireland.—In answer to Mr. Strachey, in the House of Commons, Sir J. Hibbert has said: "The Acts of 1883, 1889, and 1893 authorise the Treasury to give assistance to light railways and tramways, not exceeding a total sum of £65,000 per annum. Of this sum £30,722 is hypothecated to payments for which the Treasury has made itself liable in aid of guaranteed dividends, and on this account a sum of £21,240 was paid during the year 1894-95. The balance of the annuity of £65,000 is equivalent, when capitalised at 3 per cent., to £1,142,600, and the whole of this sum has been allocated to the lines mentioned at page 72 of the Civil Service Estimates of this year and to preliminary expenses and contingencies. The sum of £101,211 was paid on this account in the year 1894-95."

The Belfast Telephone.—Mr. Provand has asked the Postmaster-General in the House of Commons on what date the telephone trunk line was opened from Belfast to different towns in England and Wales; how many messages which had been paid for had passed over the line since then; and if the amount of business done would pay a profit after providing interest on the capital outlay and meeting all the expenses. The Postmaster-General replied that this line was opened to Liverpool, Manchester, and a few other towns on March 1. On the assumption that the honourable member referred to conversations with Belfast alone, he had to say that 16 conversations had been paid for up to the 20th ult.; but, of course, there had been other messages on the same trunk line. It was too early to judge of the financial result until further time had elapsed and the line had been placed in communication with other lines which were now in course of construction by the Department, and with the trunk lines of the telephone company which would shortly be acquired by the Department.

The Korda Thermo-Chemical Cell.—At a recent meeting of the Paris Academy, M. Désiré Korda read a paper on a "thermo chemical carbon cell." The author finds that if barium peroxide is heated to redness in contact with a carbon plate, the oxide becomes reduced to baryta, and a difference of potential of about one volt is produced, the carbon plate being negative. A similar result was obtained with cupric oxide as soon as a layer of potassium carbonate was placed between the oxide and the carbon, the difference of potential in this case amounting to 1·1 volts. The experiments were in each case performed by connecting a plate of gas-retort carbon by means of a platinum wire to one terminal of a Richard voltmeter, and placing on the carbon a few centimetres of the salt. A platinum wire dipping in the salt served to complete the circuit. On heating the carbon to a dull red heat in a Bunsen flame, a violent effervescence takes place, carbon dioxide being evolved; and the voltmeter shows a deflection corresponding to about one volt. This deflection remains constant as long as any of the higher oxide is left.

Thermo-Electric Generator.—We have received an advance proof of an article by Mr. H. B. Cox, which is to appear in our New York namesake, on the Cox thermo-electric generator for the conversion of heat directly into electrical energy. He uses gas as his heating medium. In the case of one type, in which the average gas consumption is 2½ft. per hour, varying terminal outputs may be had. For instance, machines are produced giving ½ volt and 90 amperes, 1 volt and 45 amperes, 5 volts and 9 amperes, 2 volts and 22 amperes, and 11 volts and 4 amperes. Mr. Cox claims that he has shown that a direct converter can be built which is practicable, permanent, and which shows a marked economy. While the first object in his work was to construct a machine in which mechanical and electrical effects were eliminated, the necessity for economy in fuel expense was also recognised. In the experimental work on the apparatus it was discovered that it required a particular form or kind of heat. So remarkable was the difference in output found to be with various forms and kinds of fuel that the output electrically was increased 300 per cent. by simply using the proper heat, and this increase was made with an actual saving of fuel. It is stated that the machines can successfully and commercially convert heat energy in any desired output, and that they show, even in small apparatus, a marked economy.

An Electrical Scare at the Sorbonne.—A curious accident occurred at the recent inauguration of the electric light in the Paris Sorbonne by the firm Clémançon, who have installed in this historic edifice 2,500 incandescent and 40 arc lamps. The occasion was also that of the centenary of the foundation of the Ecole Normale, and a brilliant assembly had gathered to celebrate the double event. The affair happened, just after the departure of the President of the Republic, in the large room of the Academic Council. The circuits of the incandescent lamps consisted of two leads covered with yellow silk, and the lighted candles of the chandeliers fitted with the lamps set fire, it appears, to one of the conductors, causing a short-circuit, which brought the lamps to the red, and the insulating material of the cable to melt upon the heads of the dancers. Great was the consternation, especially of the ladies; and a brave fireman, who, with considerable presence of mind, raised himself upon the shoulders of a comrade and essayed with vigorous blows of his helmet to extinguish the "fire," only succeeded in creating further alarm by smashing some of the lamps; and the apprehensions of those present were only at length allayed by an assistant of the Clémançon firm, who had been hastily summoned, and who simply switched off the chandelier.

The Battle of Keely-Cranky.—Keely, the motor man, bobs up serenely from time to time in the same way as proverbially attributed to a bad shilling. Someone who believes in him—or professes to do so—writes to the *New York Sun* to say: "I have been identified with the work of Mr. Keely for over 17 years, and have visited him in his

Digitized by Google

laboratory perhaps 50 times, and have seen the progress of his work up to this time. He has now completed his vibratory circuit of force, and will soon show the wonderful 250-h.p. commercial machine now completed, and which is now being set up in his shop. Mr. Keely claims that the all-important connection has been completed, with the result that he has gained command of an accumulation of costless force drawn from the atmosphere; or, as he expresses it, 'a sympathetic force of outreach, representing in the full receptive circuit an accumulation of polar sympathy of more than 23 tons a minute when under rotation to be distributed to the polar and dipolar circuits' of his machine. In a long article recently published, it was stated by eminent electricians 'that polar currents of great force have been discovered, if we know how to utilise them of value.' Mr. Keely made this same statement years ago, and was laughed at. He has now harnessed these polar currents for commercial use. These polar currents form the foundation, as it were, of his discoveries." We have all heard years ago the story that Keely is just about ready to show his machine, but he never seems to get any "forrader" save when some credulous person gets taken in and writes him up in a language which is not to be understanded of the people.

Personal.—A boating accident took place near Portrush the other day, three persons being drowned. Four others were rescued with much difficulty and at great peril by Mr. Traill, of the electric tramway company, and other residents of Portrush.—Mr. W. R. Brook, says the *Indian Engineer*, has made over charge of the Telegraph Department to his successor, Mr. Reynolds, and has sailed for England, thus closing a connection of over 37 years with India. Looking back to the Mutiny period, he can trace the slow development of the Indian telegraph system during the first 25 years of his service; then the quickening up all along the line as a more liberal policy was adopted and the "deferred" rate was introduced; and finally, during his own term of office, the rapid extension of the wire to every part of the country. The progress made since 1889 has indeed been remarkable, and the retiring Director-General has well earned the highest award of praise which a grateful Government can give. When he succeeded to his post there were less than 35,300 miles of line and 106,400 miles of wire: now the figures are 44,600 and 138,800 respectively. The number of departmental signalling offices has sprung from 880 to 1,350.—The City Commissioners of Sewers have appointed Mr. A. A. Voysey, their electrical inspector, electrician to the Corporation.—What the Scotch term "a short leet" has been selected by the Electric Lighting Committee of the Hampstead Vestry for the post of electrical engineer. The leet comprises the following six gentlemen, who were to be interviewed by the Vestry yesterday: Mr. G. Cottam (Hanley Corporation Station), Mr. G. B. Dunn (Metropolitan Electric Supply Company), Mr. H. D. Munro (Exeter Electric Light Company), Mr. E. Sayer (assistant, Hampstead Vestry Station), Mr. A. M. Sillar (Messrs. Statter and Co.), and Mr. J. E. Stewart (Derby Corporation).

Electricity and Lock-Gates.—The locks which have recently been completed on the ship canal at Ymuiden, near Amsterdam, are claimed to be the largest in the world. Their dimensions are: length, 200 metres; width, 25 metres; depth, 9·20 metres above low-water level. Each lock is furnished with six pairs of gates, which divide it, and permit the rapid passage of small vessels. Powerful capstans on each side of the canal assist the progress of the craft. Hand-power for working the gates and capstans was, of course, out of the question. It was necessary to choose between two systems—electricity and hydraulics. The latter, although the general method, had the disadvantage that considerable care had to be taken in winter to ensure the uninterrupted operation of the locks. Accordingly, in June, 1893, the Dutch Waterstaat Minister put the question in the form of a competition, the result of which is that Figée Bros., engineers, of Haarlem, and Schuckert and Co., of Nuremberg, authors of an electrical project, have been invited to make preliminary trials at the Ymuiden locks and lock-gates, with the view principally of determining the exact power necessary to operate the gates. For this purpose a temporary building will be constructed near the locks, and will contain the necessary machinery for producing the current, which will be transmitted by overhead wires to two capstans capable of developing a force of 1,000 kilogramme-metres per second. Strong chains or steel cables fixed on the capstans and fastened to the gates will serve to keep these with a difference of 10 centimetres between the level of the basin and the level of the canal. The definitive installation will comprise a powerful battery of accumulators, permitting in case of need the working of the gates without the aid of the dynamos. The results of the trials will be awaited with interest, but no doubt is entertained that in this case, as in so many others, electricity will offer considerable advantages over hydraulic power which has almost exclusively been employed up to the present in operating lock machinery.

The "Ingratitude" of Electrical Engineers.—We referred last week in a note to the chief subjects treated of in Prof. Unwin's "James Forrest" lecture at the Institution of Civil Engineers on the subject of "The Development of the Experimental Study of Heat Engines." A short digression was made by the lecturer, who said: "In popular writings nothing is commoner than to find the efficiency of electric machinery and of steam machinery contrasted to the great discredit of the latter. The dynamo, it is said, has an efficiency of 90 per cent. to 95 per cent., the steam-engine an efficiency of only 10 per cent. What a barbarous machine, after all the labour of a century, the steam-engine must be! The comparison is generally made by an electrical engineer, and the first reflection which occurs to one is that of all people the electrical engineer should be the last to abuse the steam-engine, for whatever may be the case in some future century, at present the dynamo is absolutely dependent on the steam-engine. Without the steam-engine the dynamo would be a useless mass of metal and wire. But passing over the moral aspect of the question—the ingratitude of the electrical engineer—the comparison is an unfair one, and shows a want of apprehension of the important law of the motivity of heat, which is one of the two fundamental laws of thermo-dynamics. Heat energy is undirected or mob energy. It lies in the nature of the terrestrial conditions in which use has to be made of it that only a fraction is convertible into directed or mechanical energy. The task of the steam-engine is to do its best with the fraction which is convertible, and in that point of view it is not an inefficient machine. The dynamo has a much easier task. Energy is supplied to it in its directed or wholly convertible form, and naturally in transforming one kind of directed energy into another kind of directed energy only a small fraction need be wasted." The supposedly ungrateful electrical engineer, however, deserves gratitude from the maker of steam-engines, whose trade has been improved by the orders received from the former.

Street Subways for Large Towns.—Mr. Charles Mason, A.M.I.C.E., surveyor to the Vestry of St. Martin-in-the-Fields, on Monday night read a paper on this

Digitized by Google

subject before the Society of Engineers. In the course of the paper, he stated that the old-fashioned method of laying underground pipes was such that a periodical inspection of the mains for ascertaining their condition or for stopping leakages, was almost impossible. Especially was this the case with the gas and electric mains, and the recent explosions in several parts of the Metropolis had imposed a duty upon those having the control of the streets to devise some better system, whereby material of whatever nature laid under ground could be easily examined from time to time. The construction of subways was the most satisfactory, and, in fact, the only, method for laying pipes and mains, so that these conditions could be complied with. He went on to say that examinations for leakages were the main cause of disturbance in the pavements, these being generally made in a haphazard kind of way, as it was somewhat a matter of guess work to define the exact spot requiring attention. In a recent examination in the Strand near Charing Cross, an irregular area of about 19 square yards was displaced by an electric light company before discovering the leakage for which a search was being made. Had the exact spot been known, the whole could have been repaired with less than one yard superficial of the road having been disturbed. This one leakage cost at least £14 to discover, apart from the cost of the actual repairs to the electric conductor. Mr. Mason described a triple subway which he had designed, in which the electric light mains (among others) were carried by brackets built into the wall, while telegraph, telephone, and lighter wires were attached to the overhead arching. Should it be necessary and desirable to construct electric transformer-chambers for the high-tension cables, these could be placed in arched openings in the division walls of the subway, but in the author's opinion all transformers should be entirely upon the property of the company owning the same. Mr. Blair, surveyor to the St. Pancras Vestry, considered that there would be danger from gas explosions if the gas-mains were carried in such subways, but Mr. Mason replied that he did not think so.

Central Technical College.—We have received the programme of this college of the City and Guilds of London Institute. In the department of physics and electrical engineering, under Prof. W. E. Ayrton, the complete course of instruction which is given is specially designed to meet the requirements of persons who desire to obtain a technical knowledge of physics, either to enable them to rightly understand the processes carried on in certain industrial operations, or to fit them to become technical teachers. The special industry to which attention is mainly directed is that of electrical engineering. The instruction is given largely by tuition in the laboratory, the lectures being rather for the purpose of aiding the students in their laboratory practice than of forming a distinct course by themselves. The laboratory work is of two kinds; that for the first-year students consisting mainly of quantitative experiments arranged for the verification of the most important well-known laws, while that for the second-year students will, in addition, be directed to training them to carry out original investigations. In the third year the work done by the more advanced students will be of an original character. In addition to the lectures and laboratory work, classes are held for the working of exercises; the students are also taught to construct and repair physical apparatus in the physics workshop. During the session, courses of lectures and laboratory instruction are given on (1) practical physics; (2) electrical technology; (3) advanced electrical technology. The laboratory course on electrical technology is given in the three electrical and magnetic research laboratories (which are fitted with more sensitive measuring apparatus than that contained in the electrical and magnetic laboratories for first-year students), in the arc lamp room, the optical testroom, and in the dynamo and motor laboratories. The latter are furnished with direct-current dynamos of the series, shunt, compound-wound, and constant-current types, as well as with alternating and multiphase current machines. These dynamos are driven from coned shafting, by means of which the speed can be varied at will. The laboratories also contain electromotors, transmission and absorption dynamometers, a large number of accumulators, transformers, commercial meters, as well as delicate electrical measuring instruments that can be used near dynamos. This laboratory course, besides experiments on dynamos, motors, transformers, accumulators, condensers, arc and incandescent lamps, etc., embraces the measurement of the strength of magnetic fields, the magnetic properties of iron, coefficients of self and mutual induction, the calibration of various commercial electrical meters, and generally the carrying out of electrical work which is too technical or too difficult for first-year students.

Alternating-Current Motors.—Mr. Alex. Rothert has read a paper on "Motors for Single and Multiple Phase Alternating Currents" before the Elektrotechnische Gesellschaft at Frankfort-on-Main. After referring briefly to the long-cherished wishes with respect to the practical manufacture of alternate-current motors, he described the various existing types of these and the action of a continuous-current motor, and remarked that in synchronous running the armature at any instant always occupies the same position relative to the field, otherwise these motors are built the same as alternating-current dynamos. He mentioned three particularly great disadvantages of the synchronous motor: (1) it does not run alone; (2) when overloaded it remains at a standstill because the rotary effort, when it comes out of the phase, is first in one direction and then in the other; (3) for exciting the field system a continuous current is necessary. Owing to these drawbacks, the use of synchronous motors is limited. They are especially suitable in the case of long-distance transmission. For instance, this system is employed in Cassel, where the current is transmitted from a remote source of water power. In order to diminish this liability to fall out of step, the armature field must be made weak and the magnet field as strong as possible. The use of continuous-current motors for alternating currents is also very unimportant. They require large dimensions, show considerable phase-retardation, and sparking at the brushes is not to be avoided. The induction motors, in which external current is carried to the armature, are better. The Behn-Eschenburg motor has also the drawback of excessive sparking. The experiments of Ferraris in 1885-86, and also those of Tesla, have led to practical results. The use of multiple-phase motors began with the Frankfort Exhibition. A rotary field is produced by three alternating currents differing 120deg. in the phase, in a ring magnet furnished with a so-called star or triangular winding. The armature consists of laminated iron, and has a closed winding in which the induced currents are produced. The motor rotates in the direction of the rotary field, and runs almost synchronously. A constant speed and easy running are the special advantages of this type. Mr. Rothert illustrated the very high efficiency of rotary-current motors, and then described those with variable numbers of revolutions constructed by Siemens and Halske, which run asynchronous. In conclusion, after describing the single-phase motor of Brown and Oerlikon—which does not start of itself—he touched upon the different usages of the alter-

Digitized by Google

nating and rotary current motors. Synchronous motors are adapted for long-distance power transmission; non-synchronous for medium powers, or where the motor has to run without attendance—for instance, in cranework. These motors can then be constructed without brushes and connecting rings. They all have the disadvantage that the speed cannot be regulated.

Machinery Users' Association.—The annual meeting of this association was held on Wednesday, Sir Wm. Houldsworth, Bart., M.P., in the chair. The total receipts for the year ended March 31 last, including balance brought forward, were £1,058, and the expenses £691, leaving a balance of £367 in hand. The committee reported that satisfactory progress had been made. They gave details of the parliamentary progress of the Bill for exempting tenants' machinery and tools from rating, which now only awaits third reading in the House of Commons, and this has been put down for June 19, when it will be the first order of the day. The committee congratulate the members of the association on the progress the Bill has made during the session, which is more than in any previous year. This success, however, has stirred its opponents to make increased efforts to obtain its rejection. A deputation from five northern assessment committees and property owners' associations met in London on March 26 last, when several members of Parliament made speeches against the Bill and an opposition campaign was inaugurated. The committee confidently rely on the tried support of those who recognise the importance of freeing the industries of the country (including agriculture) from all burdensome restrictions that tend to impair their development, to render futile this attempt to defeat a measure which the country has asked for many years past. Considerable interest was aroused by the action of Messrs. Sir Joseph Whitworth and Co., in the Chorlton-upon-Medlock Union, in raising the question of the rating of machinery by appeals against the assessment of other firms in the union, in comparison with which they considered themselves to be unfairly assessed. Several conferences took place between the association's advisers, who acted for the firms attacked by Messrs. Whitworth, and the appellants, but owing to various difficulties that arose, all the appeals were finally withdrawn, and the costs incurred were paid by Messrs. Whitworth. Certain important manufacturing centres have been considerably agitated during the past year by attempts to tax their machinery. In most cases, rather than defend their action in the law courts, the assessment committees have met manufacturers with considerable reductions. This shows the importance of having the rating of machinery placed on a satisfactory basis by Parliament. The statements made in last year's report as the system under which valuers canvass for employment attracted very considerable comment, and much indignation has been felt in industrial circles that the existence of such a system should be possible. The committee carefully considered and determined to oppose the London Valuation Bill introduced by the London County Council, which was withdrawn owing to the ruling of the Speaker that it could not be considered as a private Bill, and have also considered other matters affecting the interests of members in different localities. Questions of water supply and the disposal of manufacturers' effluent are now under consideration, and members will be fully advised of any action that it is deemed desirable to take.

Electrotherapy.—Dr. W. S. Hedley, of Brighton, who has previously dealt with the question of resuscitation from electrical shock, now contributes a long article to the *Lancet* under the title of "Apologia pro Electricitate Suâ." He states that those who have watched the solid, even brilliant, progress of electrotherapy in recent years acknowledge with regret, and not without surprise, that there is still a remnant of physicians who seriously doubt its capabilities, who refer to it as a "discredited agent," as something that has been tried and found wanting, or who, falling back upon a favourite phrase, express themselves as "disappointed in it." Of this remnant there is a certain minority even more aggressive in its attitude, more hostile in its scepticism. It is composed of those who roundly assert that neither does there exist any rational basis for the employment of electricity in medicine, nor is there any satisfactory demonstration of its curative effects; that once an agent of undoubted therapeutic promise, electricity now stands forth an admitted failure; that any good results that follow its use are due to psychical influence and rest on the baseless fabric of "suggestion." Dr. Hedley then proceeds to give a history of what has been done, and what is being done, and comes to the conclusion that, looked at from the standpoint of modern practice, the field of electro-therapeutics seems broadening. No longer limited to strictly local applications, it now embraces those procedures whose aim it is to influence, and which demonstrably can influence, the entire economy. Its object is so to utilise electro-physiological data as to influence innervation, heart action, muscular conditions, respiration, temperature, the oxidations, every functional action and metabolic change, and not least by the process darkly known as "vaso-motor influence" to modify and control the blood supply to organs and tissues. There are times when the power of electrisation to reach an internal organ will depend not on any direct action inherent in an electric current, but on an influence which, having its starting point in the electrical stimulation of some surface area, and travelling perhaps *vid* nerves of common sensation, will strike the spinal cord at some special spot, and reflected thence will find a route by filaments of the sympathetic to some particular organ, an organ thus in neural relationship, through this special segment of the cord, with that area of cutaneous surface which was the site of the electrical stimulation. France, America, and Germany are at present each the active centres of an onward movement in electro-therapeutics—a movement which experimental investigation, clinical observation, and organised association go hand-in-hand to accelerate and to strengthen. Another mark of progress appears in the fact that physiologists begin to recognise that chemical and electrical processes are inseparable from those that have hitherto been called vital, and that E.M.F. is very constantly the outcome of physiological action. There are signs that physics begins to "encroach on the domain of physiology, and that medical men are more and more turning their attention to physics." What has been called "physical biology" or "biological physics" seems already beginning to differentiate itself, and to stand out as a special branch of science. It forms a kind of neutral ground where medical and electrical science find a common holding point and a common end. To the medical man his line is clear. With the lessons of experience well in view he takes his stand upon the broad principles of electro-physics and the known action of electrical currents on vital structures. When such indications fail to guide him, and fail they often must, he will not on that account fold his arms in helpless inaction, but falling back upon an enlightened empiricism he will gently feel his way. He will "not ask, but try." He will not be afraid to acknowledge that after all is said therapeutics is to a large extent but a process of cautious experimentation.

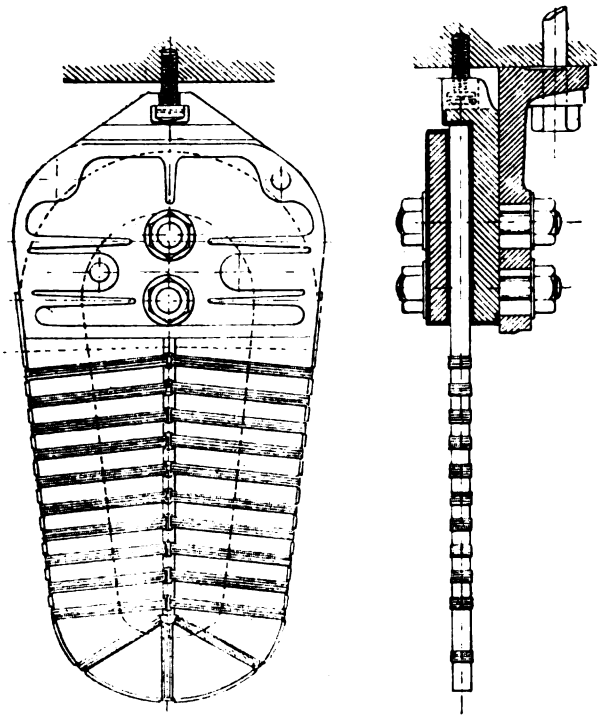
LEICESTER ELECTRICITY WORKS.

(Continued from page 502.)

The Alternators.

These machines are of the Mordey-Victoria type, of the same general design as those used in the Bankside station



FIGS. 11 AND 12.—Plan and Sectional Elevation of Mordey Alternator Coil.

of the City of London Electric Lighting Company. The armature is stationary, and in the 200-kilowatt set consists of 120 coils mounted on a gunmetal ring, which is bolted to a cast-iron frame divided into four sections. Two of these quadrants are below the floor level and two above. They are hinged about points near the horizontal centre line so that the upper quadrant can be swung back for inspection or repairs, while the lower segment can be let down into the cellars for a similar purpose. The coils can

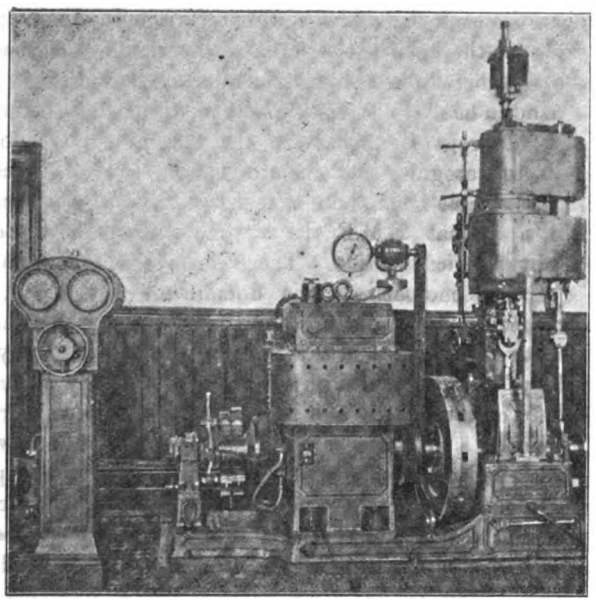


FIG. 13.—Exciter Plant, with Switch Pillar.

also be well examined *in situ* with the construction of field magnets used by the Brush Company. The two halves of the armature are connected in parallel, and an equaliser, to prevent wasteful currents circulating in the armature, is placed in one of the end girders. The field magnets consist of massive steel castings, with 60 pairs of polar projections, and excited by one large field coil placed in the centre between the claws of the magnet. The energy required for excitation with the large alternators is found to be 4,320 watts, which is 2·16 per cent. of the output.

Mr. W. M. Mordey has given long and careful attention to the perfection of the mechanical and electrical construction of the armature coils, which should conform to the following qualifications: (*a*) high insulation between coil and frame and between adjacent coils; (*b*) each coil to be mechanically strong and stiff enough to do its own share of work without mutual support from its neighbouring coils; (*c*) perfect interchangeability, so that any coil can

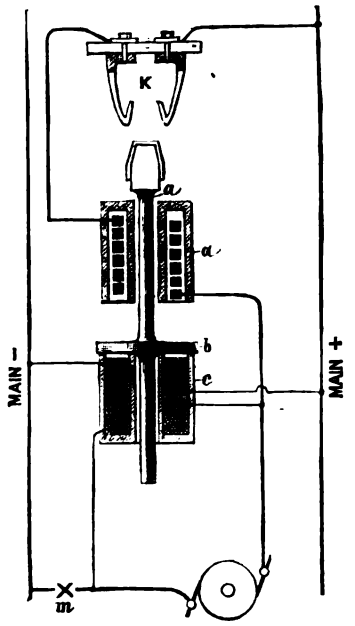

FIG. 16.—Connection in Exciter Pillar.

be fitted to any machine and immediately worked without any mechanical alternation *in situ*.

The result of his experience and successive improvements with the above aims in view is shown in Figs. 11 and 12. A radial adjustment is provided by which the

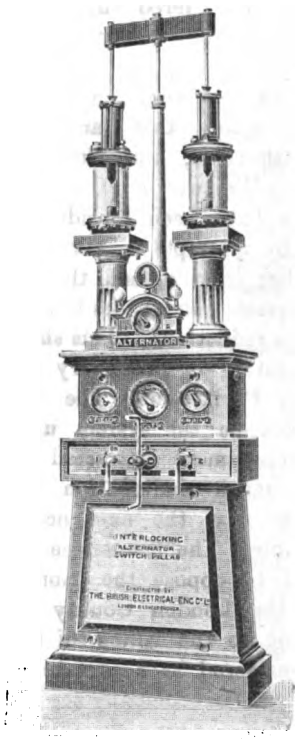

FIG. 17.—Alternator Pillar.

coils may be tightened down until they touch one another, but it is found that with these new coils mutual support is not necessary. The supports of the coil are of German silver, ebonised over all the necessary surfaces for purposes of insulation. The coil and its clamps are self-contained, and may be removed from the armature ring simply by slackening the two nuts shown at the back of the ring.

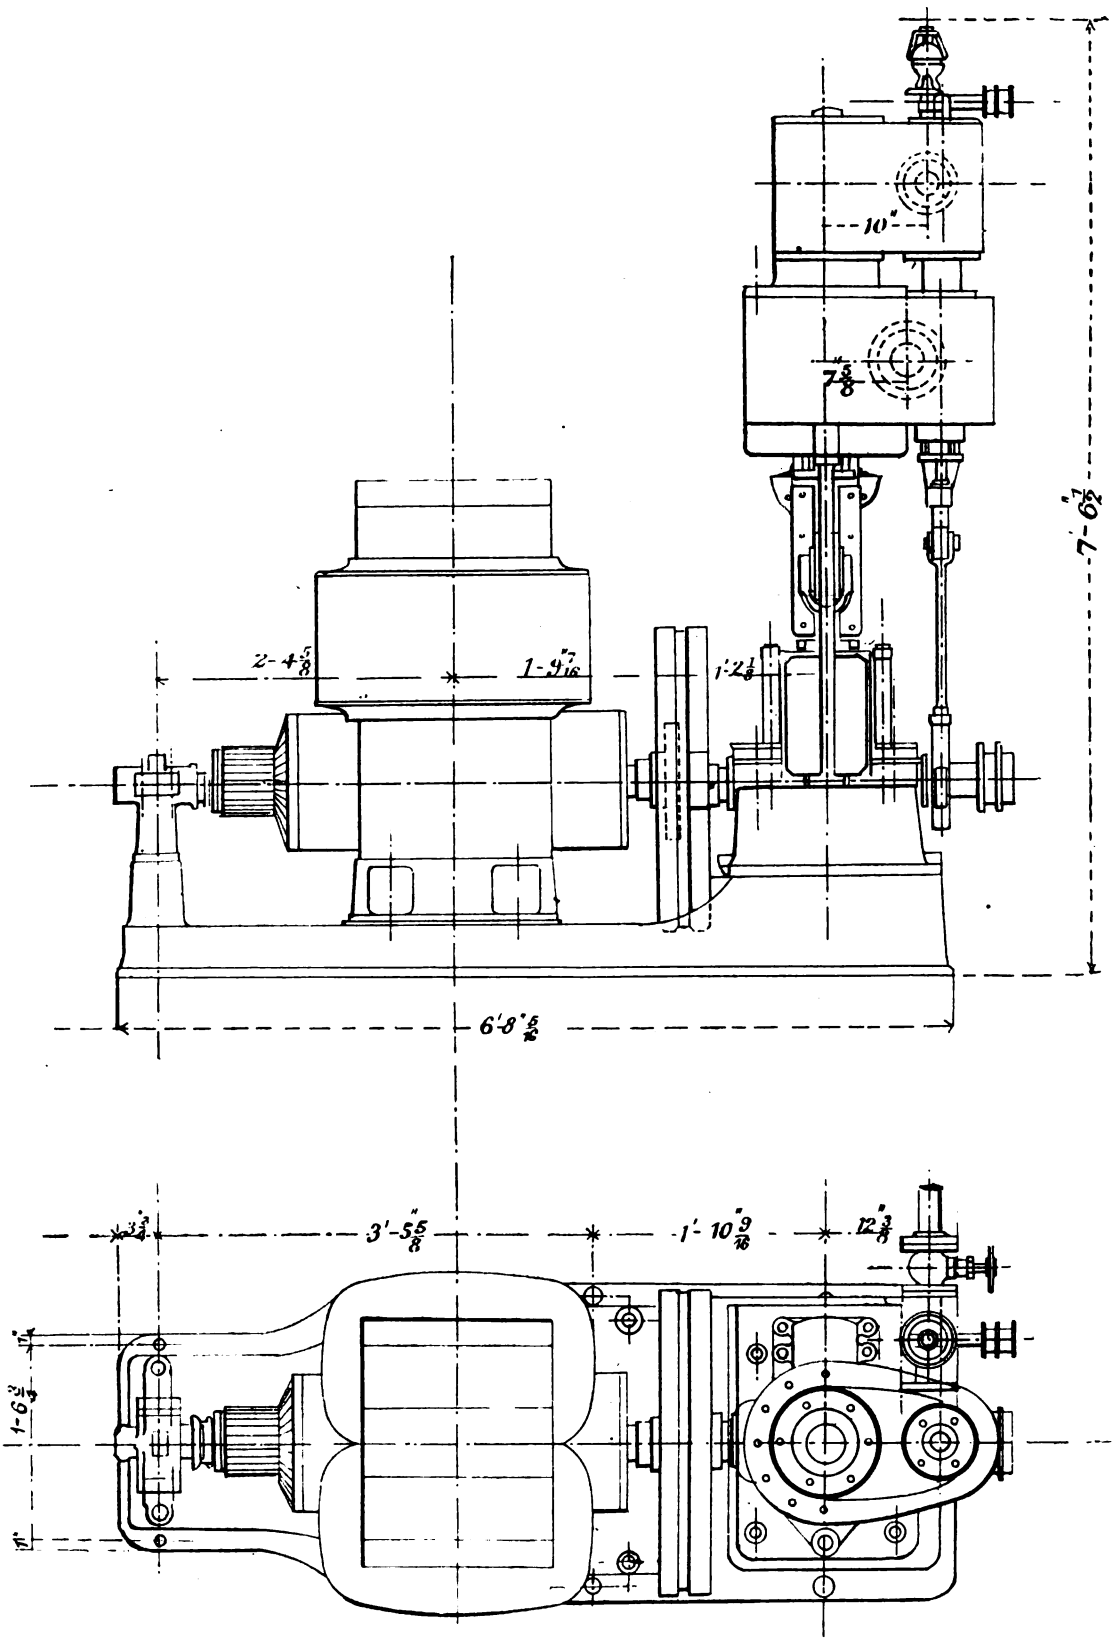
Digitized by Google

The core is of slate, and has a series of holes down the centre line. After the copper conductor has been wound on and a sheet of anti-sparking material placed over it, pressure is applied, and then the whole is bound tightly together by whipcord threaded through these holes in the core. In this way the slack usually taken up after running is removed before the coils leave the shops. The alternators at Leicester were not erected or tested at Loughborough, and since erecting in the station the armature coils have not given the slightest trouble, neither have they needed any subsequent adjustment.

The whole of the revolving parts are most carefully balanced, and run without oscillation. The bearings are made to swivel, and with this construction, combined with the Raworth coupling, assures that there can be no side thrust on the brasses.

Exciting Plant.

The exciters consist of two Brush-Falcon compound-wound direct-driven dynamos, Fig. 13, each having an output of 12,000 watts at 50 volts. Either is capable of exciting all the alternators at once. The engines, which are of Brush manufacture, have tandem compound cylinders 6in. and 10in. by 8in. stroke. Raworth's patent electric control governors are fitted to these engines, and by means of a resistance in the governor circuit the voltage of the supply from the whole of the station can be regulated from one place. Figs. 14 and 15 show the general dimen-



FIGS. 14 AND 15.—Plan and Elevation of 12-K.W. Brush Direct-Driven Plant.

Digitized by Google

sions of these sets, but the electric control governors are not shown in these drawings, but can be seen in Fig. 13.

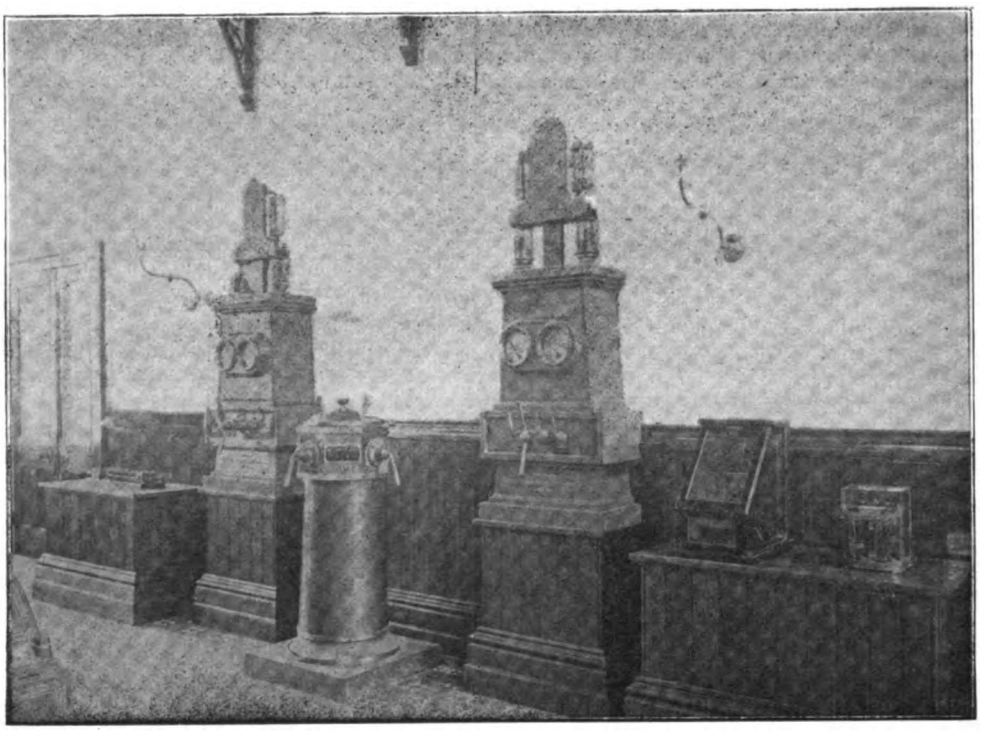


FIG. 18.—Dividing Table and Feeder Pillars.

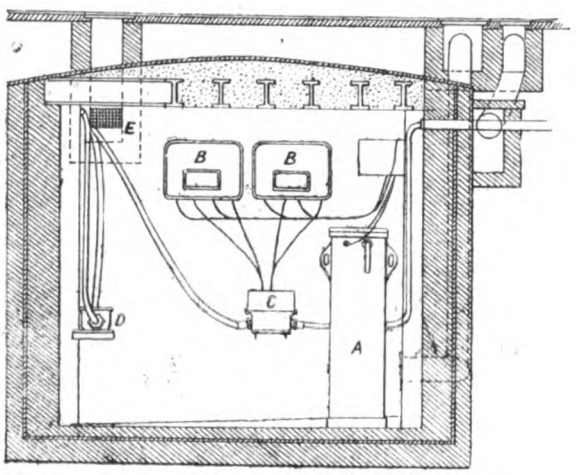
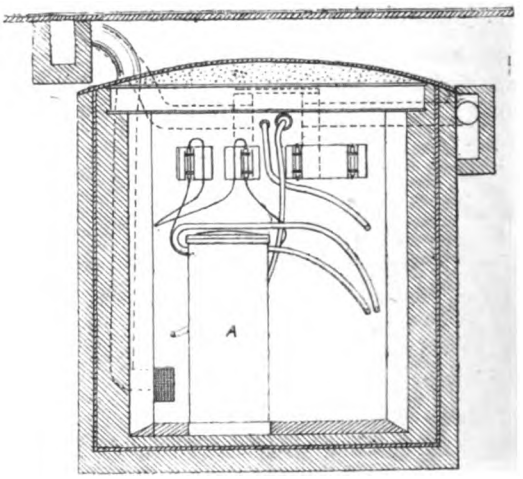
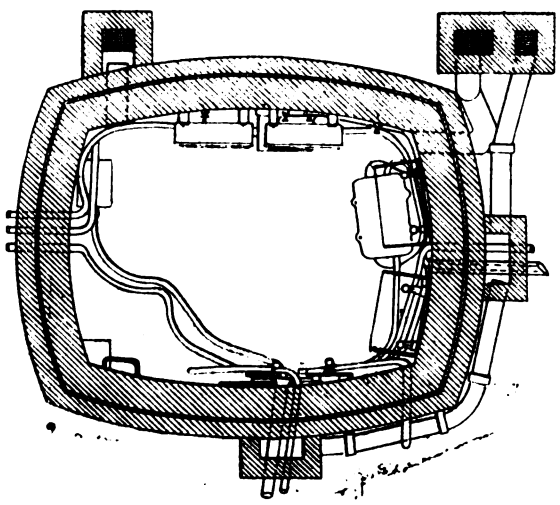
Switch Gear.

The two exciters feed on to a pair of omnibus conductors, which supply the field magnets of the alternators in parallel. Opposite each exciter stands a cast-iron switch-pillar, containing a switch, Fig. 16, which automatically closes the circuit when the E.M.F. of the exciter rises slightly above that of the omnibus conductors. The same apparatus break circuit should the exciter begin to take current from the omnibus bars. A cast-iron switch-pillar, Fig. 17, is provided for each alternator, by means of which all the operations necessary for putting that machine in or out of circuit are performed. The pillars are fitted with three iron handles, which perform the following functions: the left handle puts the exciting current on to the field magnet; the right handle puts on the synchroniser; these two operations being performed, the middle handle, which operates the main switch, is liberated and can put the alternator on to the main feeders. The closing of the main switch locks the field switch, and turning off the synchroniser locks the main switch. There is an independent trigger on the main switch, which is released by the current attaining the normal voltage. This interlocking gear assures that the alternators cannot be switched in without being excited, or the exciting current broken while the main switch is closed. Each alternator switch-pillar is provided with a rheostat for correcting the temperature resistance of the field circuit, but it is not used for regulating the E.M.F. nor for varying the load on the machine. The leads from each of these alternator pillars are connected to the dividing tables shown in the centre of Fig. 18.







FIGS. 19, 20, AND 21.—Transformer Sub-Station and Outfit.

In this pillar, which is kept carefully locked to prevent any unauthorised person tampering with it, the alternators are coupled to the two sets of concentric mains supplying

Digitized by Google

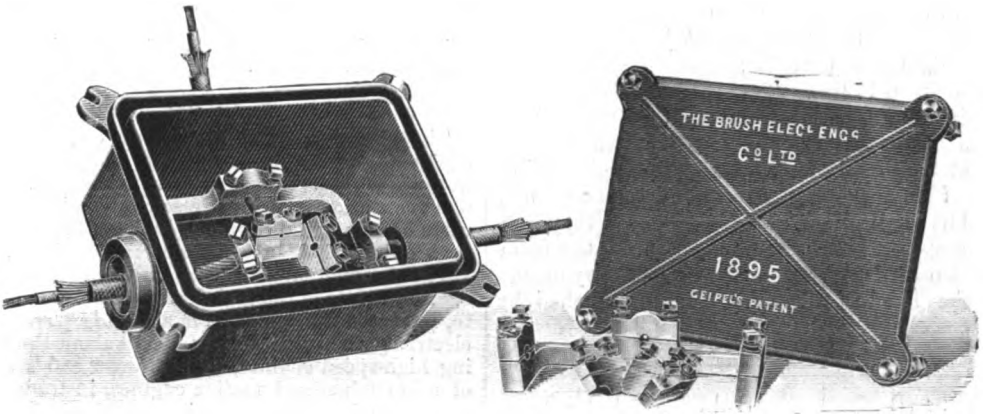
the town. Thus means are provided that two of the alternators can supply one half of the town through one feeder, while the other half is independently lighted by another alternator. This minimises the risk of total extinction of the lights, although we understand that in ordinary practice the whole of the alternators will run in parallel and supply through both feeders in parallel.

The control of the E.M.F. of the whole station, as measured at the omnibus tables, is effected by means of an electric circuit influencing the throttle-valve governors of the exciters. Each exciting engine has a solenoid arranged to act upon the adjusting lever of the governor; the speed of the engine can, therefore, be varied by varying the current in the solenoid. All the solenoids are in parallel on a circuit in which is placed a rheostat regulated by hand or automatic mechanism. It is part of the system that the controlling solenoids shall be always in circuit, so that no exciter can be started without being at the same time under the control of the switchroom. The action of the regulating circuit is to increase the speed of the exciter, so that in the event of the regulating circuit breaking down, the only effect would be that the E.M.F. would fall and would have to be raised by hand adjustment of the governors. No fuses whatever are allowed in the exciter circuits. All the main alternator fuses are of the Bates type, and the switches are immersed in water to prevent arcing.

The erection of the whole of the electrical plant has been superintended by Mr. J. J. Steinitz, on behalf of the Brush Company.

Distribution.

The system adopted is that of transformer sub-stations placed under the footpaths, each containing two or more transformers excited in parallel off high-tension mains, and feeding into a low-tension network from which private consumers are supplied. The transformer-chambers, Figs. 19, 20, and 21, are eight in number, their internal measurement being 7ft. 6in. long, 5ft. 6in. wide, and 7ft. high. The sides and ends are cambered, having a rise of 6in. The walls of the chambers are formed of good hard bricks in cement in two thicknesses, with an inch space between. This space is filled in with specially prepared asphalte, which is also continued under the paving of the floor as well as over the roof, thus making the chamber perfectly water and gas tight. The roof is formed of rolled-steel joists filled in between with cement concrete. A suitable manhole with double cover is provided for access to the chambers, which are descended by means of step-irons built into the inner thickness of wall. All the chambers have an air inlet and outlet for securing proper ventilation. The bellmouths of the pipes carrying the high-tension mains are caulked with Vulcan cement, with the object of preventing any gas finding its way into the chambers. As an additional precaution against accidents, the pipes are provided with a ½in. hole about 1ft. from the back of the wall of the chamber, which communicates with a ventilating flue. This arrangement allows any gas which finds its way into the pipes escaping before reaching the chamber. A similar arrangement with the same object is provided in connection with the low-tension cables.



FIGS. 22 AND 23.

The equipment of the sub-station is as follows, will be seen from the illustration:

(A) *Transformers.*—These are of the well-known Mordey-Victoria type. The all-day iron losses of one of these, as measured at Loughborough, shows the following excellent attainments:

Output	36,000 watts
Iron loss	281·4 watts = ·78%
Power factor	·74%
Total drop full load to no load	1·8%

(B B) Transformer switch-boxes.

(C) Joint-boxes for connecting the concentric cables in indiarubber lead. This box, which is Geipel's patent, is shown in detail in Figs. 22 and 23. The feature of the construction adopted is that, instead of having the inner conductors jointed at the same level as the outer, they are joined at a higher level, thus being more accessible, and can be disconnected without the necessity of removing the insulating compound from round the lower conductors.

(D) A similar joint-box, used in this transformer-chamber for a high-tension feeder not tapped.

(E) The air outlet for ventilation purposes. The air inlet and ventilation of the pipes can also be seen. The fuses are placed just above the transformers.

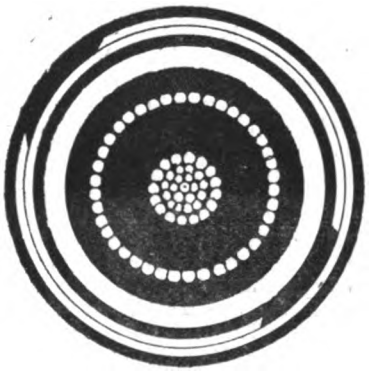


FIG. 24.—·146 sq. in. Cable, 37/·070 High-Tension Feeder.

FIG. 25.—·146 sq. in. Cable, 19/12 Low-Tension Main.

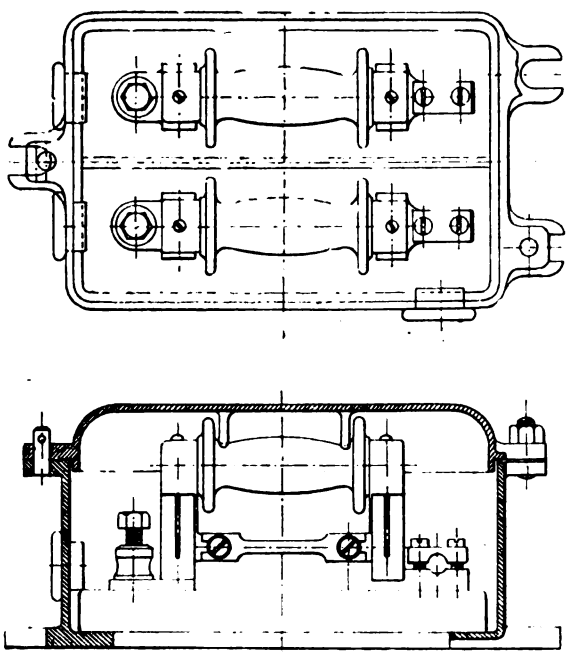
Digitized by Google

Mains.

All the cables used at Leicester are of Fowler-Waring manufacture, and for the street work are concentric, the outer conductors being earthed. Two main high-tension feeders run from the generating station in the Aylestone-road to the first transformer-chamber in Belvoir-street, a distance of 2,100 yards. They are buried in the sidewalk of the Aylstone-road 15in. below the ground. Each consists of a Fowler-Waring concentric cable, Fig. 24, the conductors of 100 per cent. conductivity copper with a sectional area of ·146 square inch highly insulated, lead-sheathed, and armoured with steel tape, with an external serving of jute soaked in compound. This high-tension cable withstood 8,000 volts in the works at North Woolwich, and 4,000 volts when jointed in position. The radial depth of fibre impregnated with hydrocarbon insulation is 0·174in. The thickness of lead is 0·115in. The insulation resistance was 3,500 megohms per mile. From the transformer-chamber at the corner of Belvoir-street and Market-street the high-tension mains consist of similar cables of ·097 square inch sectional area, but instead of being armoured, they are drawn into 3in. cast-iron pipes; these are laid in the form of a ring, any section of which can be disconnected by means of isolating switches fixed in the sub-stations, of which eight



FIGS. 28 AND 29.—House Service Box.

have been built within the compulsory area of supply. The low-tension mains, Fig. 25, having a sectional area of a ·146 square inch, are concentric, lead covered, and armoured, being laid direct in the ground, and connected together in one network. There are at present some 1,100 yards of armoured and unarmoured low-tension cable laid. House connections, Figs. 26 and 27, are made by means of concentric armoured cables jointed with wiped joints, which are protected by a tee-shaped casting. The Brush Company's new form of house service box, Figs. 28 and 29, is used on the consumers' premises; they include a double-pole switch and fuse specially arranged for connecting concentric service cables to separate house mains. The whole is enclosed in a cast-iron lock-up box of substantial design.

In conclusion, we most heartily congratulate the Corporation of Leicester on the well-equipped electric lighting station they now possess, at a cost well within the original estimate. We also congratulate the engineer, Mr. Colson, and the contractors on the success of their joint efforts, which have resulted in the production of such excellent work.

London Chamber of Commerce.—The thirtieth annual general meeting of the members of the Chamber of Commerce will be held in the council-room, Botolph House, on Tuesday, May 21, at 2.30 p.m.

INSTITUTION OF ELECTRICAL ENGINEERS, May 9.

MR. R. E. B. CROMPTON (President) in the chair.

At the commencement of the proceedings, the **Chairman** referred to the loss which the Institution had sustained by the death of Major-General Stewart, C.B., R.E., who was one of the members of the Institution when it was the Society of Telegraph Engineers and Electricians, and moved a vote of condolence to his widow and other members of the family.

Captain Sankey, who seconded the motion, testified to the high esteem in which the deceased General was held by his brother officers and those who served under him.

The following paper was then presented:

ON THE RECENT DEVELOPMENT OF THE SINGLE-ACTING HIGH-SPEED ENGINE FOR CENTRAL-STATION WORK.

BY MARK ROBINSON, MEMBER.

The success of the high-speed engine in this country is amongst the notable engineering facts of the time. It relates, in the first place, to mechanical engineering, yet it also concerns this Institution, since it is electrical engineers who are the chief users of high-speed engines; to them, in fact, it is due that such engines hold their present important position.

The presidential address at the commencement of the present session, in which the high-speed engine was favourably referred to, produced the comment in a leading professional paper, that electricians had little cause to boast about their work in developing high-speed engines, for if they "had stuck to the builders of mill engines and marine engines, instead of trying to strike out a new line of steam-engines for themselves, electric lighting would have been very much the gainer." The judgment of electrical engineers has thus been arraigned before the general body of their brethren, and it may be useful to enquire with what justice.

According to what purports to be a full list of public lighting stations, published last January in one of the principal electrical journals, the indicated horse-power installed in all the lighting stations in Great Britain was 101,390. Of this, one make of single-acting high-speed engine accounts for 53,340 h.p., or more than all other patterns put together, and even of these last, more than 4,000 i.h.p. are high-speed engines of other kinds. Engines of the mill or marine pattern figure for little in the total, and as the high-speed engine started later than its rivals, its proportion of the more recent work is even greater than the above figures would indicate. Not much apology, therefore, is needed for bringing this subject before electrical engineers.

The preponderance of one type of high-speed engine, embodying many views in conflict with those upon which other engine practice is based, virtually obliges this paper to be both a description and a defence, and may even give to it the appearance of eulogy, of that particular engine. Few but those directly interested in the manufacture of a highly-specialised machine are so conversant with it and its history as to be willing to write upon it; hence such a paper risks the charge of partisanship, and is certainly open to that of prepossession. A well-remembered charm of the late Mr. P. W. Willans's papers upon steam-engine economy lay in the fact that his conclusions were as far as possible framed to apply to engines in general; his own engine, though in all cases the one tested, was scarcely described, and certainly unpraised. The present paper, on the other hand, if it is to have any practical value, must not only describe the Willans engine, but must deal almost exclusively with its difficulties, with its successes, and with its improvements. A description of the engine, with some notes on its history, is given in an appendix.

The advantages of single action and of high speed are, however, not limited to any one engine, and they may be described generally. An engine is "single acting" when the steam acts only upon one side of the piston, the typical case being James Watt's Cornish pumping engine, and this method of using the steam has certain economic advantages in which a double-acting engine cannot share. At equal speeds, however, they are neutralised by the fact that for a given power the cylinder capacity has to be twice as great in a single as in a double acting engine, and it is not until the single-acting engine runs at twice as many revolutions as its rival that it has much advantage. This it is usually able to do, since it can be worked upon the "constant-thrust" plan, which the double-acting engine cannot be—that is to say, the piston-rod can be kept pressing against the connecting-rod, and the latter against the crank-pin, not only throughout the working stroke, but through the return stroke as well; the working parts are thus always in compression, and never in tension. The cross-head pin presses always against the same side of the bush or brass in the small end of the connecting-rod; the big-end upper brass maintains constant pressure against the crank-pin, never leaving it even momentarily; the crank-shaft presses always against the lower main bearing brasses,

Digitized by Google

never against the caps.* Of course a single-acting engine is not necessarily a "constant-thrust" engine, and special means have to be taken to make it so: the point is that these means are possible with a single-acting and are not possible with a double-acting engine, and though it is a view which is contested, it is the opinion of the author, and certainly it is a widely-held opinion, that really high speed and "constant thrust" should go together, unless in such a case as is referred to in paragraph 8.

High speed is at last recognised as a good thing in itself. A fast-running engine is, for a given power, smaller and lighter than a slow one, while a large number of small impulses per unit of time give a more even turning moment than a small number each of greater magnitude. By shorter exposure of the cylinder surfaces to successive changes of temperature, the loss by initial condensation is reduced, so that an unjacketed engine becomes as good as a jacketed one; and for many purposes, as where direct coupling to fast-running machines is required, and especially for dynamo driving, the high-speed engine has advantages which are of necessity admitted. Attempts to revive the belt-driving system in central stations, in the country which is the home of direct-driving, and after the rest of the world has almost unanimously come round to its views, will be endured in England only so long as shareholders and ratepayers remain ignorant of the waste of money it entails, while the proposal to make the naturally fast-running dynamo into a slow and enormously more costly machine, merely for the sake of allowing it to be driven direct by a slow-running engine, is not likely to meet with success in the long run. The future, however, can take care of itself; it is enough that high speed is already recognised as beneficial by all who are likely to mould future practice.

It is evident that a single-acting engine in which there is absolutely no back-lash and no reversal of stresses, and which is otherwise rightly proportioned, will run freer from wear in its brasses than a double-acting engine, at any but very moderate speeds. In the author's opinion, an ordinary double-acting engine is in danger of becoming troublesome, if it is run much more than one-third as fast as the speed at which a single-acting engine will run continuously and easily; will need very good design and careful attention if it is to run half as fast, and must be an altogether exceptional engine if it is to run two-thirds as fast without giving comparatively frequent trouble. There would probably be no difficulty in finding in use many single-acting engines of, say, 80 i.h.p. or 100 i.h.p., running at 450 revolutions per minute, which have had five years' service and upwards without one of the brasses being touched since the engine was first put to work; and it is a safe statement that if these brasses were now removed in most of them no wear would be detected without careful measurement, while if through unfavourable conditions of lubrication or otherwise appreciable wear were found, it would be absolutely without effect upon the good running of the engine. No such statement could be made of any double-acting engine; but for any purpose where the runs are limited to hours, or even to days, an ordinary double-acting engine of the same power would no doubt run at 150 revolutions without giving appreciable trouble. Such an engine, however, would have larger cylinder volume than the 450-revolution single-acting engine, and would suffer more from initial condensation, and it would hardly be trusted by most engineers for purposes (such as electrolytic work) in which an engine must run for many weeks, or even months, without stop. With special design, half speed, or 225 revolutions (giving equal cylinder volumes, but double exposure of the surfaces in each revolution), is also attainable by a double-acting engine; but few are likely to dispute the opinion that two-thirds speed—*i.e.*, 300 revolutions per minute—is not a desirable speed for an 80-h.p. double-acting engine required to run continuously for weeks or months together under commercial conditions. The author does not overlook the fact that double-acting engines are designed and made to run at even the fullest speeds of single-acting engines, and that by a combination of excellent design and workmanship with a system of forced lubrication (oil is forced into the bearings by pumps) they are able to do so. It would be out of place to refer here in detail to the author's reasons for disbelief in the ultimate acceptance of this ingenious and bold attempt to evade the natural difficulties which the case presents; it is sufficient to say that for the present the single-acting engine holds the field for high-speed work on the large scale, and, according to the most recent experience, with increasing success. Defining high speed as the highest speed which experience shows can be attained without visible disadvantage by a single-acting engine of a given power, it must be said that single action is not essential to high speed, but that it helps enormously to its successful attainment.

It may, nevertheless, be of interest to remark (though, in the author's opinion, the fact has no bearing upon electric lighting practice) that for the attainment of the extremest speeds, with large powers, a double-acting engine is to be preferred. The maintenance of constant thrust upon the brasses, which may be taken as the real essence of a single-acting engine, involves great difficulties when certain limits are exceeded, and if through any temporary reason the constant thrust is lost and the engine becomes double acting as to its brasses, there will be serious chances of rapid wear, and even of such hammering as to cause fracture. In a double-acting engine, on the contrary, provision is made from the beginning for the change of stress at the end of each stroke; it is a mere question of brute strength in the parts, and since they are always under observation for excessive wear, and periodical adjustments are a part of the system, there is little danger of serious damage. For torpedo boats and other cases where the greatest power must be obtained from the least weight, and where knock and frequent adjustment are comparatively unimportant, double-acting engines are plainly best. But few electrical engineers would care to entrust the continuous running of their stations to engines of this type, or to go through quite the same engine-room experiences as are rightly accepted on board a "catcher."

The class of engine called "high speed" in America is usually a double-acting engine, capable of running from one-half to two-thirds the speed of the corresponding single-acting engine of this country. As such it has already been referred to generally, and though it usually runs well, it has no claim to special consideration, certainly not on the ground of economy.

The effect of "single action" in lessening wear upon the brasses must be obvious, and the connection is almost as close between single action and the beautifully simple method of automatic lubrication by the splash of the cranks in an oil-chamber; the latter cannot be adopted without risk of much inconvenience, where brasses have to be under constant observation. The very small bearing friction which results partly from this system of lubrication, and partly from the absence of back-lash, is also unattainable in a double-acting engine.

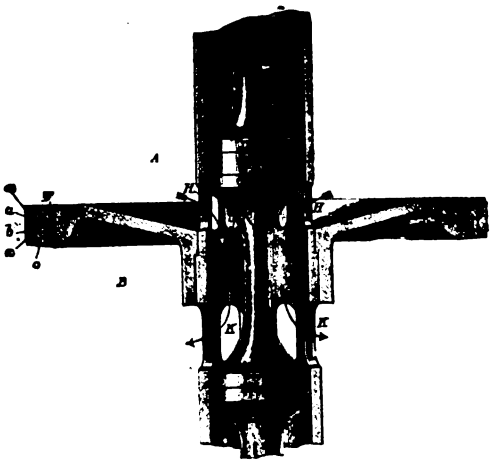


FIG. 1.—Vertical section through piston, showing rings *a* and *b*, which break joint; spring *c* for lightly forcing the rings outwards; spring follower plate F, with holes through it, admitting steam to the space behind the spring *c*.

So far only the general and more obvious advantages of the single-acting engine have been considered. Now it is proposed to describe in some detail three important features in the particular engine which has become, in this country at least, the type of the class; none of them have yet attracted as much attention as perhaps they deserve. They are: (*a*) the special system of packing rings for pistons, valves, and glands; (*b*) the special provision for internal drainage; (*c*) the Cornish cycle, or "transfer plan." All three are directly related to the single-acting principle. All, except the Cornish transfer, are peculiar to the Willans engine, and none of them could possibly be adopted in a double-acting engine. All are of high value in promoting steam economy.

Packing Rings (*a*).—One of Mr. Willans's latest improvements in his engine was the system of packing rings shown in Fig. 1, where A is the working end of the cylinder; the pressure in B, below the piston, is materially less upon the down (or working) stroke than that above it, but on the up or exhaust stroke it is practically the same: it is never less, unless in the exceptional case of a looped diagram. There are two rings, *a* and *b*, breaking joint, and turned of the same thickness throughout, which exactly fit the cylinder before they are divided; *c* is a cast-iron spring ring, turned eccentric and slightly too large for the cylinder: great care is taken to have true surfaces at *x*. The follower, F, is a thin steel plate, very slightly dished, so as to have a slight initial pressure upon the top of the rings. It is perforated, to let steam from A enter the space behind the spring, which it tends to push outward lightly during the up stroke, comparatively strongly during the down stroke. The rings are held against the lower flange of the piston body, G, not only by the spring follower, F, but by the steam pressure on the top of the rings; on the up stroke, when

* A single-acting engine can be run with the parts always in tension, and never in compression, with equal ease, but the contrary plan is practically the best.

Digitized by Google

there is less pressure above the rings, their friction against the cylinder is sufficient to keep them seated on the piston body. It will be noticed in this system, first, that the outward pressure on the rings is relieved during the ineffective stroke; and, secondly, that the principle of "constant thrust" is applied to the rings as regards end-play. At all times, whether the piston moves one way or the other, and equally while it reverses its movement on the dead points, the piston rings are held closely down upon the piston flange, and there is none of that wear of the rings endways which tends to arise in all double-acting engines, owing to the friction of the rings causing them to lag behind, so that they are pushed one way

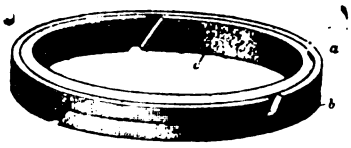

FIG. 2.—Perspective view of set of piston rings complete. Two rings, *a* and *b*, breaking joint, and spring *c*. The steam presses against the inner surface of *c*. NOTE.—The thickness of the rings is exaggerated relatively to their diameter, for greater clearness.

by the piston body and the other by the junk ring or follower. Even if wear arose (which under ordinary circumstances it cannot) the spring follower would follow it up: there would still be no hammering of the ring between the two sides of the groove. There is thus no increase of ring leakage; the longer the use, the tighter the rings. The piston valves are on the same system as regards constant pressure of the rings and other parts against each other, but they are not steam-packed (see Fig. 3). They are separated by suitable cast distance-pieces, with their ends faced to lie against the rings. All are strung together upon a steel tie-rod, with a kind of spring washer under the nut at the end. All parts are free to slide upon each other sideways; all are designed to be held together, without the possibility of hammering upon each other, by the pressure of the steam (in the steam-chest) upon the uppermost valve, aided by the spring washer referred to. The gland rings, used instead of stuffing-boxes (see Fig. 4), are upon exactly the same system as the main piston rings; they are simply piston rings pressing inwards instead of outwards, and guarded against end-play in exactly the same manner. Steam is admitted behind them, as in the main pistons.

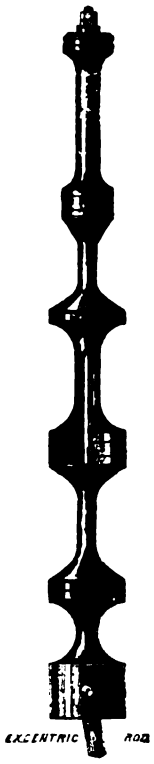

FIG. 3.—View partly in elevation, partly in section, of a line of piston valves from a compound engine.

This construction of the various piston and other rings is perhaps the most interesting application of the constant-thrust principle in the engine, but it has not been arrived at without long experiment and some changes. It was originally attempted to dispense with steam pressure behind the piston and gland rings—in fact, to exclude it—and many will remember the collapsing of the rings, especially when the steam was very wet, or when over-much oil was used. Under some circumstances a ring could always be set collapsing by increasing the oil supply: it is an old experience that water (or oil) will get behind a ring where steam alone will fail to pass. Once separated from the cylinder wall, the ring was bound to spring inwards, until stopped by the butting of its ends: this butting and the subsequent spring outwards caused much noise and wear, and sometimes breakage of the ring, with, of course, waste of steam. Instead of a spring-plate follower, there was at first a fixed follower—which allowed end-play, and so wear, as in other engines—and afterwards a solid follower pressed down by spring washers, which also was not satisfactory. When "steam-packing" was first adopted, the holes in the follower were not made large enough to let the full pressure in behind the rings in the short time available, and so the system was imperfect. These defects have been corrected, and the system seems now to be not only perfectly successful, but in a sense beyond rivalry; for it would evidently be impossible to apply it in a double-acting engine—that is, in an engine where the preponderance of pressure changes from one side of the piston to the other. It may be added that very careful measurement, based upon some three years' experience, shows that the wear in the cylinders is less than with the earlier rings, whose outward pressure was given entirely by springs. With rings which practically do not wear at all, and which are bound to keep tight whether they wear or not, it is not surprising that the economy of the engine increases with use.

Drainage (*b*).—The best-drained double-acting engines are probably horizontal engines with separate Corliss or similar exhaust valves beneath the cylinder. The water lying on or draining down towards the cylinder bottom is pushed along by the piston until it reaches the exhaust-port, but unfortunately

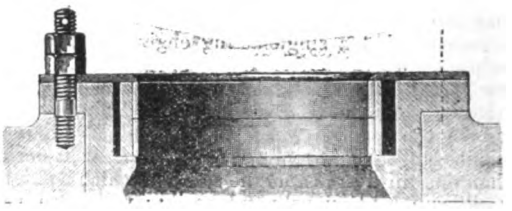

FIG. 4.—Sectional view of a steam gland box.

only just before the moment of closing; however, it fills the port, and lies in it until the exhaust opens again—ready, it is to be feared, to rob the incoming steam of some of its heat during the next admission, and so to increase initial condensation. In vertical engines, at the bottom end of the cylinder the drainage may act continuously, so far as gravity can effect it, during the whole exhaust stroke, but at the upper end the water will rest on and be carried up by the piston until it rises above the port, when, as in the horizontal engine, only a very brief time is available for it to run away; much water probably lies permanently upon the piston, with injurious results from the point of view of initial condensation. If the exhaust-port is also the admission port, the water cannot even lie there until the next exhaust; it is thrown back into the cylinder by the incoming steam. In none of these cases is the drainage satisfactory.

The drainage arrangements in the Willans central-valve engine offer a striking contrast to the foregoing (see Fig. 1). The piston is dished downwards in the centre, not so much with the idea that the water lying on the piston will drain into the centre by itself, but to utilise the inertia of the water to drive it towards the centre during the rapid up stroke of the piston. There is a ring of ports, H H, in the trunk or hollow piston-rod, flush with the surface of the piston, and of course moving with it, and during the whole exhaust stroke there is a rush of steam from the sides towards these ports in the centre, sweeping over the face of the piston and assisting the action last referred to. In fact, the exhaust-port is always in the best possible place for drainage; it is as though the exhaust-port in the horizontal Corliss engine moved along the cylinder bottom so as to be always just ahead of the piston. The water is out of the cylinder before the port closes, nor is there any clearance space in the port—that is, between the cylinder and the valve—where it could lie; there is practically no clearance. It is an ideal exhaust arrangement, and there is no apparent possibility of applying either it, or anything else as good, to a double-acting engine. It is probable that it involves a saving of about 15 per cent. in the steam consumption in comparison with other vertical engines in which ordinary slide or piston valves are used common to admission and exhaust. In Fig. 1 the central valve, L, is shown in its relatively highest position; the exhaust steam (and water) are passing away into the space B, as shown by the arrows, through the ports H H and K K. B is, of course, the receiver; it is in one sense the exhaust-chamber of the working cylinder, A, in another sense the steam-chest of the succeeding cylinder, if there be one. It will be understood that when the valve, L, is below the ports, H H, steam passes into the cylinder from the upper part of the hollow piston-rod.

The "Cornish Cycle."—In the Cornish single-acting pumping engine the steam acts only on the top of the piston, the space below being at the time in communication with the condenser.

Digitized by Google

To develop the power of the engine it would only be necessary to open communication during the up stroke between the upper end of the cylinder and the condenser, and to maintain communication permanently between the lower end and the condenser: the piston would ascend *in equilibrio*, with vacuum on both sides of it. Viewing the upper end of the cylinder by itself, this is exactly what takes place in every ordinary double-acting engine, and the whole arrangement described, including permanent vacuum below the piston, is the most obvious and natural arrangement for a single-acting engine. In Watt's Cornish engine there is, however, another valve which cuts off the space below the piston from the condenser, at the moment when the steam above the piston commences to exhaust, and the exhaust takes place from above the piston into the space below it, and not direct to the condenser; the piston still ascends *in equilibrio*, but with higher pressure steam on each

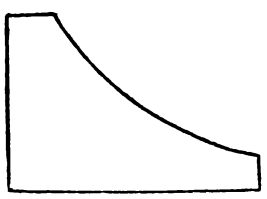

FIG. 5.

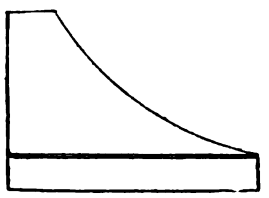

FIG. 6.

side of it. By this system Watt raised his pumping engine to a pitch of excellence never attained by his later double-acting engines; in fact, so economical (for a simple engine) is the old Cornish engine that in the controversies attending the introduction of the modern compound engine, the former was quoted to show that a simple engine could work as economically as a compound. The claim was excessive, except at very low pressures, but neither side realised that the Cornish engine is not a simple engine—it is half-way to a compound. Fig. 5 is a theoretical diagram from a simple engine in which the working cylinder opens alternately to the boiler and to the condenser. If it is also single-acting, and advantage is taken of that fact to introduce the Cornish cycle, the two diagrams given in Fig. 6 are obtained from the two ends of the cylinder, instead of the single diagram in Fig. 5. There is the same expansion in a single cylinder, but the range of temperature in it is only from admission temperature to release temperature, and not to condenser temperature. In other words, though the expansion is in one stage, the fall in temperature is divided over two; hence a great reduction in initial condensation, and marked economy.

(To be continued.)

DISCUSSION.

The **Chairman**, in opening the discussion, said that the great progress in electrical engineering dated from the time that Mr. Willans invented the high-speed engine.

Mr. Raworth said that he did not quite agree with Mr. Robinson in considering that electricity would not have advanced so rapidly as it had done but for his engine. He was a very great admirer of the enclosed engine. There were many single-acting engines before the Willans engine, which dated back to 1874. He could remember the time, in the early days of electricity, that Mr. Brotherhood's engine was greatly in demand by electrical engineers. Mr. Willans was stimulated by this fact. The speaker had not been greatly indebted to the builders of mill engines. His experience has been that in every instance they had entirely failed to grasp the situation. When he was an apprentice the same battle between the horizontal slow-speed engine and the beam engine was taking place as was now occurring between the vertical high-speed engine and the horizontal slow-speed engine. He greatly admired the Willans engine. It had some extremely good points, and he had used some with very great success. Mr. Robinson had treated of some points in its internal construction on which we were previously ignorant. This ingenious machine had one drawback—a rather serious one—it was a Chinese puzzle. You could not take out any one of the parts in order to see whether that part was in proper order or not. He did not concur with Mr. Robinson on the subject of wear. He gave Mr. Robinson credit for the improvements he had introduced into the engine since Mr. Willans decease. An ordinary vertical engine properly constructed would, he said, run with as great efficiency as, if not greater than, the Willans engine. An ordinary Tangye engine would give from 90 per cent. upwards in brake efficiency, but this would not be so in the case of a horizontal engine. He considered that the high speed of the Willans engine was not due to the constant thrust, but to the short stroke. He, however, heartily agreed that electrical engineers were greatly indebted to Messrs. Willans and Robinson for the specially highly-developed machine which they had put into their hands.

Mr. W. H. Booth stated that in his paper Mr. Robinson had referred to the overlapping of temperature ranges in the ordinary engine which did not occur in the Willans engine. He thought this was not quite right, and on the blackboard showed diagrams of different types of engines. In the ordinary engine there was no overlapping if properly designed and properly set.

Mr. Carter stated that the same point had occurred to him, and gave a diagram to show that the fluctuation of temperature ranges in the Cornish engine did not take place in two cylinders.

Mr. Bailey said that the relative cost of the different methods of driving were not what might have been supposed. He had, on behalf of the Government, called for tenders for an engine and dynamo. He received offers, from firms who all turned out good work, for a slow-speed horizontal engine and dynamo, a comparatively slow-speed vertical engine and dynamo, and for a high-speed engine and dynamo. It might have been thought that the last named as being the smallest would have been the cheapest, but this was not the case. The dearest was the slow-speed, and the cheapest was the medium vertical engine and dynamo.

The discussion was then adjourned.

There was on view a zero-torque electricity meter, invented by Mr. Joseph Edmonson, a description of which was circulated.

The following is a list of the candidates balloted for:

Foreign Member.—Don Rafael Casado, Valladolid, Spain.

Member.—Stanley Bright, Tilbury Dock, Essex.

Associates.—Cornelius Francis Fielding, 89, Patrick-street, Cork; Adam Rutherford, 14, Hill-street, Garnet Hill, Glasgow, N.B.; Rigby Wason, 8, Sussex-gardens, London, W.

Student.—John Harold Wray, Cemetery Lodge, Blackpool.

WHAT, WHEN, AND WHERE.

Institution of Electrical Engineers.

May 17, 8 p.m.—Students' Meeting in the Library of the Institution, 28, Victoria-street. "Aluminium," by Gerald C. Allingham.

Royal Institution, Albemarle-street, Piccadilly, W.

May 10, 9 p.m.—"A Recent Journey in Afghanistan," by the Hon. G. N. Curzon, M.P.

May 11, 3 p.m.—"Italian Musical Instruments of the 16th, 17th, and 18th Centuries," by Arnold Dolmelsch.

May 14, 3 p.m.—"Thirty Years' Progress in Biological Science," by Prof. E. Ray Lankester.

May 16, 3 p.m.—"The Liquification of Gases," by Prof. Dewar.

Society of Arts, John-street, Adelphi, Strand.

May 13, 8 p.m.—Cantor Lecture by James Douglas on "The Recent Metallurgy of Copper, Lead, Gold, and Silver in America." Lecture IV.

May 15, 8 p.m.—"Means for Mitigating the Fading of Pigments,' by Captain W. de W. Abney, C.B., F.R.S.

Physical Society, Burlington House.

May 10.—"The Iodine Voltmeter," by E. F. Herroun. "A New Method in Harmonic Analysis," by A. Sharp.

Northern Society of Electrical Engineers.

May 13, 7 p.m.—At the Palatine Hotel, Hunt's Bank, Manchester, Council meeting; 8 p.m., special general meeting; 8.30 p.m., ordinary general meeting. Paper on "The Uses of Accumulators," by J. C. Howell.

North-East Coast Institution of Engineers and Shipbuilders.

May 14, 7.30 p.m.—In the Lecture Hall of the Literary and Philosophical Society of Newcastle-upon-Tyne. Closing business meeting of the session. The discussion on Henry Foster's paper on "The Application of the Electric Arc to Machinery, Boiler Repairs, etc.," will be concluded. The discussion on S. O. Kendall's paper on "Turret-Deck Cargo Steamers" will be concluded. The discussion on G. H Baines's paper on "The Metric System of Weights and Measures (a Plea for its Adoption in the United Kingdom)" will be resumed by Colonel A. Robson, who will move a resolution in favour of the adoption of the system.

Cheltenham.

May 16.—The Corporation will take over the central electric light station from Messrs. Siemens, and a dinner will be given by Alderman Norman, chairman of the Electric Light Committee.

Electric Traction at Oporto.—The first town in the Peninsula to have an electric tramway will, it is said, be Oporto, and the contract for it has been secured, over the heads of German competitors, by the French Thomson-Houston Company. The city authorities have insisted that the first trial shall be made on the line which presents the greatest difficulties, one on which the gradients are as heavy as 1 in 10, and the curves are numerous. The length of the line is about two miles. There will be three carriages, each fitted with two 25-h.p. motors, current for which will be supplied by a 100-kilowatt dynamo driven by a Farcot engine of 150 h.p. The central station is well on its way towards completion, and the line will shortly be laid

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XIV. of new series of "The Electrical Engineer" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers or binding can be obtained, price 2s.

EDUCATION.

The question of the best means of becoming conversant with the subjects covered by the term "electrical engineering" is yet to be settled on hard-and-fast lines. Most of the men now holding high positions in the profession have been self-educated. Owing to the rapid developments of the industry, it follows that the men actually engaged in improving the various details know far more of the subject than most of the authorised teachers. The vast amount of information to be acquired by a young man now entering the profession necessitates some system of teaching beyond the workshop practice. We hold that without the shop practice, and subsequent training in the treatment of the commercial problems met with in daily practice, no man can become an electrical engineer. But we also maintain that the man who confines himself to his own particular work, and considers that he knows everything, will rapidly become a drag on the industry. What is needed is a careful study of the first principles of electricity and magnetism, with special reference to their application and practice. The instruction given under the Science and Art syllabus is doubtless good in its way, but a glance at the questions set in this examination will show that they are on subjects not useful to the electrical engineer. The questions as to the coupling of primary batteries to obtain maximum current, the behaviour of floating corks pierced by magnetised needles, and the relative advantages of cat-skins and silk in the production of electricity will afford harmless recreation to many, but very little bread and butter. No doubt the gentleman who excels in these intricate problems may make a living teaching others, but dynamo-makers or central-station engineers would not value that knowledge at twenty shillings a week. The City and Guilds of London Institute have come to the rescue, and by giving grants have created a new system of teaching, which is of great service to the young men employed in the electrical industries. This institute has at different times retained the services of such men as W. H. Preece, Gisbert Kapp, Silvanus Thompson, and James Swinburne as their examiners. These gentlemen, who have had great experience in the profession, usually set what we consider to be common-sense, practical questions. The men who have acquired the information necessary to successfully pass these examinations are fitted to attack any ordinary trouble that may occur to machinery under their charge. They must also have a good knowledge of the steps by which the perfection in the various details of electrical machinery have been arrived at, and also the reasons why certain supply companies pay dividend while others do not through the defective systems employed. We also know, from the reports of the examiners to the institute, that the answers sent in do improve in quality year by year. This shows that by requiring a high standard of marks for a pass, the teachers themselves have been spurred on. One thing we believe would make these examinations more useful to young electrical engineers, and that is a report to them of the errors found in the answers. To do this individually would be

Digitized by Google

impossible, except at great cost, and the erroneous notions common to, say, 20 per cent. of the students on any one question might be noted. We wish the City and Guilds of London further success in their educational efforts.

It has been suggested to us that as the City Guilds have supplemented the Science and Art examinations, so it is possible for us to supplement both. With this object in view, we have resolved to extend our sphere of operations. Hitherto we have given the questions, and recently the answers to some of the questions. We now invite our readers—and especially our student readers—to send us the answers to any one section, and have arranged with the gentleman who obtained the silver medal in the honours grade in 1892 to adjudicate upon the solutions, and to comment upon the errors most frequently arising in these answers. It is with some diffidence that we offer to the gentlemen whose answers we print an acknowledgment of their success in the shape of books, but we think this will not be taken as an introduction of the guessing prize system into technical literature. Of course it is understood that the answers sent in are the sole work of the gentlemen who send them. It seems to us that a professional commentary upon the answers ought to be of great advantage to students. Hitherto they pass or they fail, and few ever realise the points upon which they and the examiners differed.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

CITY AND GUILDS EXAMINATION.

SIR,—In taking Mr. Howard's figure for the cross-section of the cable, you must have overlooked the fact that he had worked out the problem as though the resistance was proportional, instead of inversely proportional, to the sectional area of a conductor.

As some of our younger friends may be not a little puzzled at the discrepancy of the answers given by the contributor and Mr. Howard, I thought it would be of interest if the full working of the problem was shown, so have done so.

(*a*) Total current required $= \frac{2,000}{10} = 200$ amperes.

Permissible drop = 2 volts.

Resistance of conductor $= \frac{\text{drop in volts}}{\text{amperes}} = \frac{2}{200} = \cdot01$ ohm.

(·01 ohm will be the resistance of 2,000 × 4 = 4,000ft. of mains—lead and return.)

Resistance of a conductor varies directly as the length and inversely as cross-section.

Resistance of Cu bar 4,000ft. long = ·008 × 4 = ·032 ohm.

Then as ·01 : ·032 :: 1 square inch : *a* square inch = 3·2 *square inches.*

(*b*) Current supplied from middle = 100 amperes.

Drop as before = 2 volts.

Resistance $= \frac{2}{100} = \cdot02$ ohm for 2,000ft. of main (lead and return).

Resistance of 2,000ft. of Cu bar = ·008 × 2 = ·016 ohm.

Then as ·02 : ·016 :: 1 square inch to *x* square inch = ·8 *square inch.*

The answers point out very clearly the advantage of placing the plant as near the centre of supply as possible.—

Yours, etc., HALDANE G. COTSWORTH,
Lecturer in Electrical Engineering,
North Wilts. Technical School, Swindon.

SIR,—Your solutions of the City and Guilds of London examination papers are very much appreciated by a numerous section of your readers, but as the answers to No. 6 appear to me incorrect, I offer the following, feeling sure there are many who will be expecting something more to be said on the subject.

(*a*) 2,000ft. × 2 = 4,000ft. frontage.

$\frac{4,000}{10} = 400$ amperes required.

$\frac{400}{2} = 200$ amperes average current.

200 R = 2. R = ·01 ohm.

$\cdot008 \times \frac{4,000}{1,000} = \cdot032$ resistance 4,000ft. of 1in. area.

$\frac{\cdot032}{\cdot01} = 3\cdot2$ area (square inches).

(*b*) $\frac{2,000}{10} = 200$ amperes each way.

$\frac{200}{2} = 100$ amperes average current.

100 R = 2. R = ·02 ohm.

$\cdot008 \times \frac{2,000}{1,000} = \cdot016$ resistance 2,000ft. of 1in. area.

$\frac{\cdot016}{\cdot02} = \cdot8$ square inch.

Yours, etc., ALEX. WROE.
93, Casella-road, New Cross, S.E., May 7, 1895.

SIR,—In looking over this week's *Electrical Engineer* I noticed a correction by Mr. Henley L. Howard of a City and Guilds examination question.

The proper solution is—

Total current required = 200 × 2 amperes (*i.e.*, calculating return wire) = 400 amperes.

$$R = \frac{E}{C} = \frac{2}{400} = \cdot005 \text{ ohm.}$$

·005 : ·016 :: 1 : *x*

= ·005) ·016 (3·2
15
10
10

Sectional area = 3·2 square inches.

Mr. Howard makes the mistake of saying that the resistances are proportional to the areas instead of inversely proportional. Thus he says

·016ω : ·01ω :: 1 : *x*,

instead of ·01 : ·016 :: 1 : *x*.

This latter gives 1·6 square inches. Now multiply by 2 for the two wires, then

1·6 × 2 = 3·2 square inches.

Yours, etc., HUGH G. MCHAFFIE.
Eastwood, Thornliebank, Glasgow, May 7, 1895.

P.S.—Of course, in case (*b*) the section is only half that of case (*a*)—viz., 1·6 square inches.

SIR,—I still think that there is an error in the answer given to Question 6 of the City and Guilds examination published in this week's *Electrical Engineer*. I have worked it out several times and get the following result:

(*a*) The mean current along street = 100 amperes;

$\therefore 100 \times r = 2 \therefore r = \cdot02$ ohm.

The resistance of 4,000ft. of one square inch of copper = ·032 ohm;

$\therefore$ ·02 : ·032 :: 1 : *x*;

$\therefore x = 1\cdot6$ square inches.—*Answer.*

Similarly—

(*b*) $50 \times r = 2$;

$\therefore r = \cdot04$ ohm.

Digitized by Google

The resistance of 2,000ft. of one square inch copper = ·016 ohm ;

$$\therefore \cdot 04 : \cdot 016 :: 1 : x;$$

$$\therefore x = \cdot 4 \text{ square inch.}—\textit{Answer.}$$

Yours, etc., G. M. SHEPHERD.

Brockley, May 5, 1895.

[This question is raising much interesting discussion. We would point out to Mr. Cotsworth that 200 amperes is the maximum value of the current, and when the mean value is taken—*i.e.*, 100 amperes—the resistance of the line equals 0 02 ohm. Mr. Wroe takes the word "frontage" to mean both sides of the street, which we consider is rather a liberal reading of the question, but his answer is correct under that assumption. Mr. H. G. McHaffie's calculation and assumption are not easily followed, but his footnote, that the section, when the current is supplied midway, is half that when supplied from one end, is decidedly wrong. Mr. G. M. Shepherd is correct in his reply, and would take full marks for his answer.—ED. *E. E.*]

CITY AND GUILDS OF LONDON INSTITUTE.

ANSWERS TO THE QUESTIONS IN ELECTRIC LIGHTING AND POWER TRANSMISSION.

ORDINARY EXAMINATION, 1894.

(Continued from page 505.)

4. State relative advantages and disadvantages of the two following systems of distributing alternate currents: (a) transformers in consumers' houses, (b) transformers in sub-stations.

The advantages of placing transformers in consumers' houses are as follow:

(1) In straggling districts the great cost of low-tension mains of sufficient area to give constant voltage is thus avoided.
(2) Reasonably constant voltage is provided.
(3) Each consumer gets a direct supply with any chances of failure through faults in sub-station or on low-tension mains.

The disadvantages of this system are mostly on the side of the company providing the light:

(1) Each transformer must be ample to supply the maximum demand of the consumer it supplies. Hence aggregate power of transformers to be provided is excessive.
(2) This gives an excessive no-load loss, especially as small transformers are less efficient than large ones.
(3) The prime cost of transformers is more, but the total cost is less than with the sub-station system and low-tension mains.

The advantages of the sub-station system are as follow:
(1) The total power of transformers is less.
(2) The transformers are worked at more even loads, and hence more economically.
(3) The transformers in themselves are more efficient.
(4) No high pressure in consumers' houses.

The only disadvantage of this system is that of cost, which forbids its use in any but well-populated districts, where there is good demand for light.

5. Give full-size hand-sketch of a commutator, 6in. in diameter, 4in. face, showing in section how the plates are supported and insulated.

This can be obtained from any good text-book on the subject.

8. Sketch the connections of a Wheatstone's bridge, showing how it is connected to the resistance to be measured (See Fig. 8.)

I. Shows theoretical diagram.
II. Wheatstone's bridge—box form.
III. Thick copper strips for connecting up resistances to be measured.

11. State the circumstances under which it is economical to work glow lamps above their normal voltages.

The normal voltage of a glow lamp is the pressure required to give the nominal candle-power of the lamp, and if it is desired to obtain the maximum amount of light for a given amount of electrical energy, it is economical to work above the normal voltage, as the light produced increases as the sixth power (approximately) of the pressure in volts, whilst the consumption of the energy being only as the second power. The objection to increasing the normal efficiency of the lamp in this way is that the life of the lamp is diminished enormously. Prof. Ayrton, from a prolonged series of experiments, has shown that it is cheaper to burn a glow lamp for 200 hours at 104 volts than for 600 hours at 100 volts.

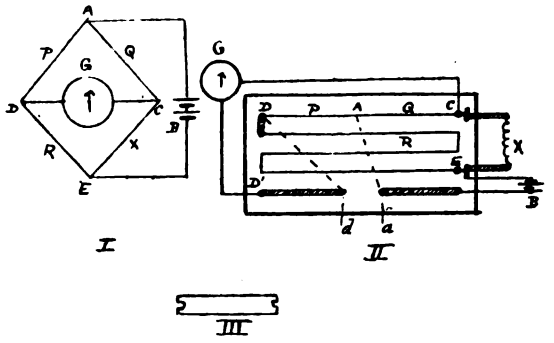

FIG. 8.

It is also advisable, if the cost of the energy is low, to increase the pressure above the normal after the lamp has been used for, say, 200 hours at the normal pressure, since with time the resistance of the filament increases, and the light decreases. In this case the normal efficiency is maintained throughout, and the additional expense for energy is almost counterbalanced by the saving in the cost of early renewals.

12. What rules govern the design of motor-generators? Upon what does the speed of them depend?

A motor-generator, or continuous-current transformer, differs from an ordinary generator in that the armature is wound with two sets of coils—the primary and secondary. According to theory, the *coefficient of transformation*, p, is equal to the ratio of the number of turns on the two coils—thus, $p = s_1/s_2$. The following rules govern the design of motor-generators:

(1) The quantity of copper in the primary coil should be equal to that in the secondary.
(2) The voltages are proportional to the number of armature-turns on the primary and secondary.
(3) The sectional areas of the windings should be proportional to the number of amperes, since the number of ampere-turns of the primary should equal the number of ampere-turns of the secondary.
(4) The coefficient of transformation is independent of the speed or the strength of the field used.

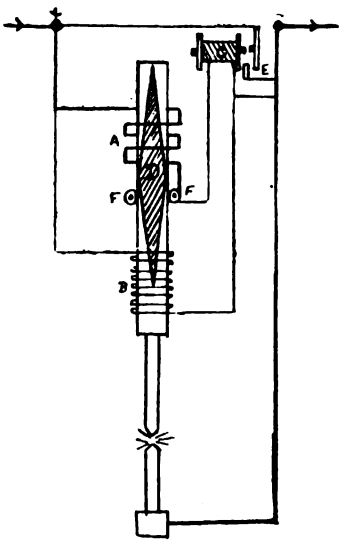
The speed of the generator depends on the strength of the field magnets and on the primary voltage.

13. Describe and sketch some form of automatic cut-out for series arc lamps, and explain its working.

All series arc lamps require an automatic cut-out, so that if the lamp refuses to work the current may be shunted round the lamp, so that the rest of the circuit is not interfered with. In the sketch, the feeding and striking mechanism is represented diagrammatically by the coils A and B. The coil A carries the main current for producing the arc, whilst the coil B is a shunt to A. The part, however, which we have to consider is the automatic cut-out shown at C. This consists of an electromagnet wound with very fine wire, placed in shunt between F and the negative terminal. F is the point where the main current enters the positive carbon-holder, and when from any reason the lamp fails to work, the pressure between the terminals of the electromagnet, C, becomes great enough to send sufficient current through C to mag-

Digitized by Google

netise the core to such an extent that the armature, E, is attracted, and a spring automatically closes the circuit. This cuts the lamp out, as it will be noticed that the armature is connected to the positive terminal of the lamp.



14. Give the number of storage cells required for a 100-volt private house installation. Also state maximum charging voltage, and say how many cells must be connected with the regulating switch.

The least number of cells required for a 100-volt private house installation is 54, and since the pressure at the beginning of the discharge is slightly in excess of two volts, 50 cells will probably maintain for some time a pressure of 100 volts at the terminals of the most distant lamp. It must not be forgotten that there is a gradual drop in the pressure along the mains, the excess over 100 volts given by the 50 cells being required for this purpose. Five cells—*i.e.*, the 50th, 51st, 52nd, 53rd, and 54th cells—must be connected to the regulating switch, so that an extra cell may be switched in immediately, should the pressure fall below that required for the lamps. In charging, $2\frac{1}{2}$ volts must be allowed for each cell, so that the maximum charging voltage is $2\frac{1}{2} \times 54$, or 135 volts.

POINTS OF INTEREST IN THE DEVELOPMENT OF ELECTRICITY SUPPLY AT BRIGHTON.*

BY ARTHUR WRIGHT, ELECTRICAL ENGINEER, BRIGHTON ELECTRICITY WORKS.

Perhaps the title the author has chosen may, at first sight, appear to assume too much, but he trusts he will be able to interest the majority of the members by acquainting them with certain facts connected with the gradual development of electricity supply in Brighton, especially when he states that, as far as he has been able to determine, Brighton was the first town in England (1) to possess a central station erected for the express purpose of supplying the general public with electricity; (2) in which the inhabitants had the opportunity of paying for the electricity they actually consumed; (3) to have the advantage, or the reverse, of having had electricity supplied by more than four distinct systems of electric distribution during the last 10 years; (4) to have been the first town to adopt a differential system of charging for the electricity consumed, based on the actual cost of supplying it to each individual customer; (5) in which electricity has been supplied from one central station, both by the continuous and alternating systems of distribution simultaneously.

The author proposes to briefly relate the principal facts in connection with the first three of the above statements, and to deal more fully with Nos. 4 and 5, as these two last features of the Brighton supply system will probably have the most interest for the members. The chief points in connection with the history of the development of the electricity supply in Brighton are the following: In 1881 the Brighton Corporation instituted some arc lighting experiments on the Marine-parade; the cost, however, of running the machinery made the magnificent illumination then obtained far too great a luxury for it to be continued. At the end of the same year Messrs. Hammond and Co. decided to give the inhabitants of Brighton an opportunity of trying the electric light on their own premises, and for this purpose the author was instructed to erect a small plant and to run the necessary overhead wires. As far as he can learn, this was the first attempt in England to offer the general public an opportunity of having the electric light without having to incur the expense and nuisance involved in putting down generating plant on their own premises. The machinery was placed in Messrs. Reed and Sons' foundry yard in North-road, and overhead wires were run from this point to the principal business thoroughfares. The supply was started early in February, 1882, and since that time the inhabitants of Brighton have always had an opportunity of using electricity and becoming acquainted with its many advantages. It is partly to this long acquaintance with the electric light, among other things, that the recent rapid extension of its use in Brighton is probably due. For the first 16 months after the station was started only arc lamps were supplied, and these were charged for at fixed rental per month until April, 1883, when it was recognised that it would greatly add to the economic working of the supply station to charge for the lamps in proportion to the length of time they were burnt, and in that month was started the system of charging the consumers on a sliding scale system, based on the use they made of the generating plant. As there were no meters in existence then capable of measuring the current, the plan was adopted of determining the consumption by means of the number of carbons burnt. Reference will be made later to the exact terms of the sliding scale adopted. In June, 1883, incandescent lamps began to be supplied from the same high-tension mains as the arc lamps. The system of supplying them is now generally known as the multiple-series system. These lamps were charged for at a fixed rental until April, 1884, when electrolytic meters were devised to actually measure the consumption of electricity by these incandescent lamps. The current consumed in them, as measured by the meters, was charged for on a similar differential basis. In 1885 the Brighton business of the Hammond Company was turned into a separate joint-stock company, and began paying regular dividends in 1886. The business gradually grew, notwithstanding the high rate of charge adopted, equivalent in most instances to about 1s. 4d. per Board of Trade unit. In 1888 the high-tension continuous-current system was replaced throughout the town by the high-tension alternating-transformer system. The change over was effected by means of installing storage battery stations, and charging these by the high-tension continuous current. The greater simplicity of the transformer system gave another great impetus to the business, and when the author resigned his position as engineer to the company in 1889, the capital amounted to about £12,000, and the annual sale of electricity was at the rate of 120,000 units. After that date the business went on increasing to the extent of selling 140,000 units per annum until the year 1891, when in September the Corporation electricity works started supplying electricity on the two-wire low-tension system. When, early in 1893, the result of the Corporation's first year's working was to show that with even on the admittedly inefficient two-wire system electricity could be supplied from a well-organised station to yield a small profit at 7d. per unit, the ultimate extinction of the old company became inevitable, and negotiations were soon commenced for the purchase of the goodwill of the company by the Corporation; the result being in the following year the company's customers were transferred to the Corporation's mains. In 1893 the Corporation, recognising that the two-wire system could never be capable of supplying economically the whole of the borough from their one station, and the greater efficiency of the three-wire system, converted their entire system to the latter form. In the same year they carried out the electric lighting of the King's-road, which work constituted, so the author is informed, the first piece of street-lighting by means of arc

* Paper read before the Association of Municipal and County Engineers at Brighton on May 4.

Digitized by Google

lamps run from the ordinary low-tension distributing mains. In 1894 the Corporation extended the distributing mains in all directions of the borough, and put down a high-tension alternating plant for supplying the purely residential districts in the north of the town. It is in these districts that the unique system has been developed of supplying electricity at light loads by the continuous current, and at heavy loads through the medium of high-tension alternating feeders. Something will be said about this special feature presently.

The following two tables, which are based on the latest published results of most of the central electricity supply stations in the United Kingdom, prove that in 1894 the actual cost, exclusive of redemption and interest of supplying electricity from the Brighton Corporation's station was less than from any other central station in Great Britain, and that the sale of electricity per inhabitant, taking all the towns having more than 50,000 inhabitants, was greatest in Brighton. When it is recognised that at the end of this year the capital sunk in the Corporation electricity works will probably reach £160,000, that nearly a million units will be sold during the year, that most of the principal streets will be electrically lighted, and that the annual consumption of electricity per inhabitant will in all probability reach the high figure of eight units, the members will see how rapidly the electricity undertaking is developing.

ACTUAL COST IN PENCE PER UNIT, EXCLUSIVE OF REDEMPTION AND INTEREST FOR THE SUPPLY OF ELECTRICITY FROM THE VARIOUS SUPPLY STATIONS.

Brighton	2·3
Liverpool	2·46

Leeds	3·11
Birmingham	3·54
City of London	3·72

If the members will extend their indulgence a little longer, the author proposes to go somewhat fully into the two most distinctive features of the Brighton Corporation electricity supply—viz., the method of charging for electricity consumed, and the system of distributing it in the residential scattered districts.

ANNUAL SALE OF ELECTRICITY IN UNITS PER INHABITANT IN THE TOWNS OF OVER 50,000 INHABITANTS OF THE UNITED KINGDOM.

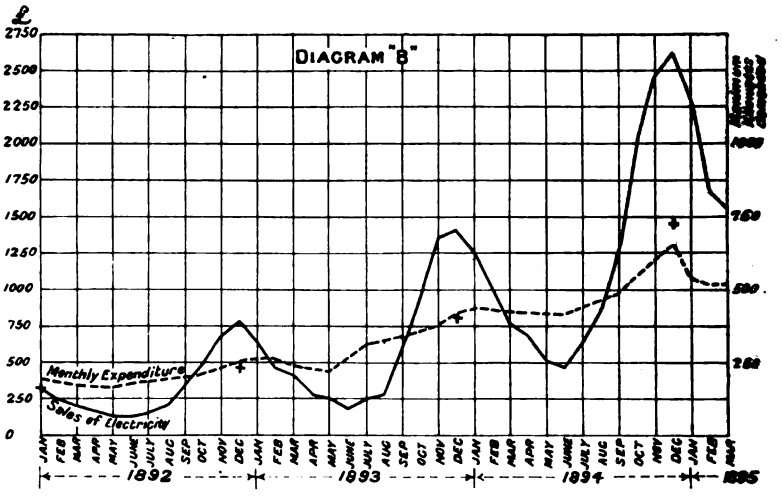
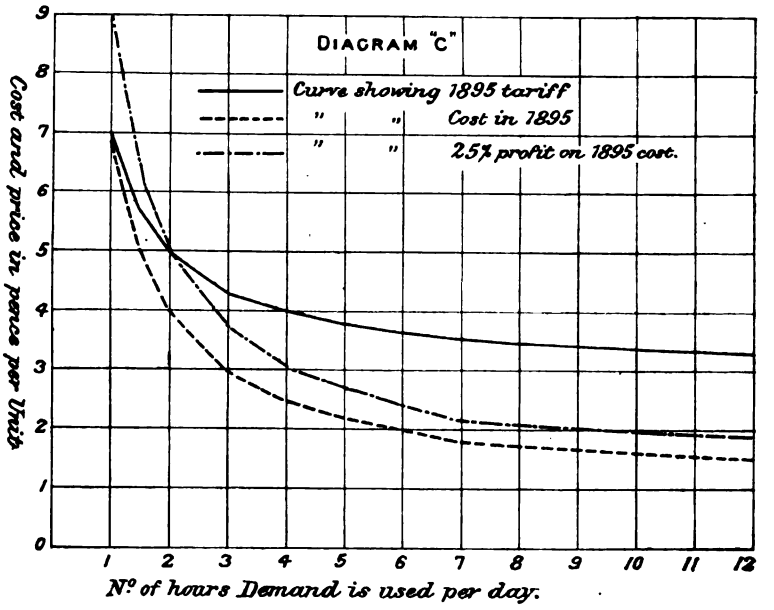
It does not seem to be sufficiently well recognised among engineers that the cost to electricity supply stations of continuing to produce electricity after everything has been put in a state of readiness to do so constitutes an extremely small proportion of the total expenditure. In order to make this truth more clear to the members the author is enabled to state, from the experience of the last three and a half years' working of the Brighton Corporation station, that the cost of having to be ready to supply electricity in Brighton in 1895 will probably amount to 80 per cent. of the total annual expenditure; the Diagram B will show clearly how very slightly the total monthly cost of running the Brighton station since January, 1892, to the present time varies, compared to the variation in the corresponding sales of electricity. The dotted line shows how the total monthly expenditure has varied during the different years, and the solid line the variation during these years of the monthly sales of electricity, the latter being taken for purposes of comparison at 6d. per unit. From this diagram it can be shown that the monthly costs only vary on the average about a quarter as much as the monthly sales do. Another point may be noticed in Diagram B. The crosses indicate the points representing the maximum call on the plant in the different years. One conclusion to be drawn from these curves is that the total monthly expenditure depends much more on the maximum rate at which the generating plant has to supply electricity during any year, than on the actual amount of electricity that has been supplied. This fact the author recognised in April, 1883, when, before meters were devised, he charged the consumers supplied by the old Hammond Company 6s. per arc lamp per week, and 1s. 6d. per carbon used; and after meters had been devised for the incandescent service, the charge was made at the rate of 1d. per lamp-hour if the lamps were not used three hours per day, and ½d. otherwise.

The present method of charging for electricity consumed adopted by the Brighton Corporation is an improvement on the above system, but still based on the same principles. In 1895 the charge for electricity consumed by anyone in Brighton is reduced to 3d. per unit as soon as the proper proportion of cost of having to be ready to supply that individual has been paid for by the revenue derived from his previous consumption in the same half-year being charged at 7d. per unit. This, in the year 1895, happens to be after the use of his greatest demand for one hour per day on the average. By means of this equitable tariff the Corporation are enabled to offer consumers who use





Digitized by Google

their demand regularly four hours a day electricity at 4d. per unit, although coal costs the Corporation over 20s. a ton. All electricity consumed in Brighton, whether it be by private individuals or by the Corporation for street-lighting and other purposes, is charged on this basis.

The members will note from Diagram C and its accompanying table how rapidly the cost of supplying electricity diminishes in Brighton according to the length of time the demand is used per day, and they will probably agree with the author in thinking that for street-lighting (the demand being used in this case on the average nearly 11 hours per day, under which circumstances electricity can be supplied at 2d. per unit with a fair margin of profit), the time cannot be far distant when every street in the neighbourhood of the distributing mains will be electrically lighted, for there is no other suitable form of artificial illumination which can compete with electricity at this price.

From the repeated consideration of what items make up the total cost of supplying electricity, and recognising how small in stations of about the size of the present Brighton one the actual cost of running bears to the total cost of supply, the author is inclined to think that central-station engineers in the past have devoted too much of their time to the reduction of the running costs, and so have been compelled to neglect the important question of how to diminish the much greater standing costs involved in supplying electricity.

Now, with regard to the last feature of interest in the Brighton system—viz., the use in the residential districts of low-tension continuous current at light loads, and of high-tension alternating currents at periods of heavy load—the author thinks much credit ought to be given to Mr. Ward Leonard, an American electrical engineer, who pointed out in 1892 that the obvious corollary from the well-recognised fact of the low-tension system being most efficient at light loads and the high-tension system at heavy loads must be that some combination of the two ought to give the greatest efficiency; and it was clear that, providing the details could be satisfactorily worked out, as they have now been, it must necessarily be more economical and safer to run only the high-tension alternating system when the demand is heavy, and at all other times to supply the residential districts from the low-tension continuous-current system, than to continue to supply by means of alternating currents when the only reason for their use has ceased to exist — viz., big loads at big distances.

The map exhibited shows the distributing network, and where the combined system is used in the northern parts of Brighton. The circles represent the transformer-chambers, from which the low-tension distributing mains in the streets are supplied at times of high loads, and the circles with crosses the points where the connecting up to the low-tension distributing network takes place on the load becoming small. As meters are now procurable which will register equally accurately with alternating or continuous currents, there seems to the author to be no objection to this combined system; and when it is remembered how the periods of light load on the average last 10 times as long as the periods of heavy load, it must be clearly unnecessary to supply by means of the high-tension feeders and transformers those parts of the town which can be so much more economically supplied by low tension through the ordinary distributing main.

On concluding this somewhat lengthy paper, the author would like to state that the rapid development of the electric light at Brighton, besides being due to the long advertisement electricity has had here, must be greatly attributed to the splendidly liberal way in which the Brighton Corporation, through the Lighting Committee, have interpreted their duties as the business managers of the electricity undertaking—in supplying nearly every business street in the borough, and the principal residential districts, with electricity distributing mains; in recognising at an early date what a big undertaking and financial help to the town it might ultimately become; and the members, after visiting the works and seeing the extensions in progress there, will in all probability confirm these views.

WILL THE ELECTRIC MOTOR SUPERSEDE STEAM LOCOMOTIVES?

This is the title of an article by Mr. Joseph Wetzler which appears in the current issue of *Scribner*, and which on the page headings an intelligent proof reader has converted into "Will the Electric Motor supersede Steam?" which is quite another story.

Mr. Wetzler argues strongly in favour of the adoption of electric traction on railways, the conclusions derived from his arguments being as follows: (1) that the electric arts to-day are sufficiently advanced to supply the apparatus to operate successfully trains or single cars at speeds greater than have yet been attained by the steam locomotives; (2) that the operation of trains at such speeds is subject only to the considerations of economy, or, in other words, that people can travel at a speed perhaps up to 100 miles an hour and over, if they are willing to pay for it; (3) that the successful introduction of electricity on existing steam roads will probably require a change in the methods of handling passengers and freight, the single car on small or small train unit, operated at frequent intervals, taking the place of the present long train. In conclusion, the author states his firm belief that all railroads will be eventually operated electrically. The first changes from steam will probably be made on short suburban roads where the traffic is heavy and the trains are run at frequent intervals, and thus approximate more closely to the ideal conditions of the economical electric railway. These electric spurs will then be gradually extended until in the course of time the entire line will be adapted to the new order of affairs, and a new generation of railroad officers, less wedded to the older methods, will have come into existence. So far as new light railways are concerned, such as those contemplated in England at the present time, and which are rapidly increasing in the United States, electricity presents advantages which cannot be disputed. It has even been suggested that such agricultural roads might largely increase their income by supplying electric power for farming operations in the districts through which they pass. Some trolley roads in the United States do this now.

CITY AND GUILDS OF LONDON INSTITUTE TECHNOLOGICAL EXAMINATIONS, 1895.

ELECTRIC LIGHTING AND POWER DISTRIBUTION.

PRELIMINARY EXAMINATION.

Instructions.

No certificates will be given to candidates on the results of this preliminary examination, but their successes will be notified.

Candidates may take the ordinary grade without having passed the preliminary examination, or both examinations may be taken in the same year.

No candidate who has already passed in either grade of this subject can present himself for the preliminary examination.

The number of the question must be placed before the answer in the worked paper.

Not more than 10 questions to be answered.

Three hours allowed for this examination.

1. Give a diagram of the Post Office form of Wheatstone bridge, showing the connections.

2. Why are electric bells apt to work badly when coupled in series?

3. Where should fuses be placed in an electric lighting installation? And why?

4. A dynamo is 100 yards from a house, the conductor has a resistance of 0·002 ohm per yard, and there are 150 30-watt 100-volt lamps to be fed. What E.M.F. must the dynamo give?

5. Give a diagram with connections of a relay working an electric bell.

6. How would you test the insulation in a building you had wired?

7. What are transformers, and what are they for?

Digitized by Google

8. How many 16-c.p. lamps, taking four watts per candle, can be run off a dynamo giving 7 e.h.p.

9. Why can a leaden bullet be fired further than a piece of wood of same shape and size?

10. If a man supports a weight of 10lb. for 17 minutes, does he do any work? If so, how much?

11. What are watt, pound, horse-power, volt, ampere, and ohm? Give any relations you can between them.

12. What is the three-wire system, and what is the good of it?

13. Two lamps of 100 and 150 ohms each, when running, are put in parallel with each other, and the pair is put in series with a lamp of 100 ohms. What E.M.F. will be needed on the system in order that it may consume 250 watts?

14. What is generally the difference between voltmeters and ampere-meters of the same type?

15. Why does an electromagnet pull so much less if you take out the iron core and replace it with a brass one?

16. Why are glow lamps generally run in parallel and arc lamps in series?

17. Define the terms: insulation, insulator, battery, switch, condenser, electromotive force, relay, depolariser, vacuum tube, electrode.

18. What is the white metal used for the tips of the contacts in electric bells? Why is silver not used for this purpose?

19. Sketch the arrangement of wires and switches that would enable a staircase lamp to be turned off or turned on from either the foot of the stairs or from the head of the stairs.

20. There is an electric bell at A and another at B, with a single line of wire between them. Show by sketches what arrangement of cells and switches are required that a person at either end can call up on the other bell without ringing that at his own end.

ALTERNATING AND INTERRUPTED ELECTRIC CURRENTS.*

BY PROF. GEORGE FORBES, M.A., F.R.S., M.I.C.E.

LECTURE II.

In my last lecture I indicated my desire during the course to illustrate a good deal the phenomena that occurred in using interrupted and alternating electric currents by means of mechanical analogies; and I think you will have already seen that, in certain cases at least, these mechanical analogies are of very great help to us in understanding what is going on. I propose to carry on the same method—through the present lecture at any rate. I concluded the last lecture by showing you by means of such mechanical analogies that we were able to form a clearer conception, as it seemed to me, of what is going on in a submarine cable than we would be able to without such mechanical analogy.

Now, I am very anxious to prevent anyone here from being led to draw too much from these mechanical analogies, and I warn you that they require a considerable amount of care in dealing with them. In going a step further, sometimes one is apt to miss the complete analogy, and so to be led to wrong deductions. This is not the case with the submarine cable which I showed you. In that case the analogy is, I may say, almost absolutely complete. There is only one defect in that analogy, and it is a trivial one—the resistance to the current is represented by the friction of the glycerine and water in this tall tube to the thread inside which is being twisted, and the current is represented by the velocity of rotation of that thread. Now, the force opposing the motion in the case of this glycerine varies as the square of the velocity. In the analogy the resistance ought to vary as the velocity. The opposing force varies as the square of the current instead of as the current, and that is the only defective part of the analogy; and it is really of very little consequence. As you all saw last day, it does not interfere with the very perfect representation of what is going on in a submarine cable. In fact, those who are accustomed to read the signals for a submarine cable agree that they cannot be distinguished from the signals given by this twisted thread. I said last lecture that these analogies would enable me to dispense with mathematical formulæ in explaining some obscure phenomena to you, but I would also wish to say that I think that these analogies are of more use really to the mathematician than to anybody else, because such analogies enable the mathematician to gain a clearer grasp of the quantities he is dealing with, and to treat them more easily than he would be able to do otherwise. In fact, I may say that Clerk Maxwell, in the whole of his great work on electricity, was merely working with mechanical analogies, although he does not say so in the book. It is obvious to anyone who reads that book that he was working out mechanical problems the whole time, knowing that the mechanical results at which he arrived would apply equally well to the electrical phenomena, and that instead of putting mass, momentum, and all those mechanical equivalents, he put the electrical equivalents. That is perfectly obvious, and if any proof of it was wanted it is in his invention of that word "electric displacement," which is a little puzzling to the electricians; but as soon as we realise that it is a mechanical equivalent the difficulty disappears.

Now, I was a little hurried last week at the end of my lecture in the demonstration of this apparatus, and it is such a very complete reproduction of what goes on in an Atlantic cable that I wish to make it a little more clear. At the top of this thread I have a spindle, with guides or bearings, wholly supported by a spring. On the spindle is a disc with vanes. There are also two brass jets, through either of which I can send a current of air to twist the thread in one direction or the other. These currents of air are manipulated from below. I may blow into the pipe, or I may use a reservoir of air, as I did on the last occasion, and the rotation is given to right or left by the two keys on the table, which open the air-valves and let the air pass in. The string itself is so chosen that it represents a long Atlantic cable. The way in which the measurements are made is this. To see that it represents a cable, you first, with a definite pressure of air, allow the string to rotate steadily round at a steady speed. Suppose it makes a revolution in a second. Then, with the same pressure, holding the bottom part of the string, or restraining it by means of magnets, apply the same air pressure and see how much twist it gives. It gives, perhaps, 10 revolutions. Divide that 10 revolutions by the one revolution, and that 10 gives you a constant of the cable; it gives you the ratio of the charge to the current, or the product of the capacity into the resistance; that defines the quality of the cable exactly, and the number of turns that the top of the string can give defines the capacity of the cable as a condenser. I will not delay you further to explain the ways in which this is an extremely close analogy, because it will become tedious. Those of you who have followed me so far, and have any interest in submarine cables, will see the very close analogy which there is.

I have placed upon a table here a number of electrical measurements which can be taken, and their analogies. I have simply put them up there as a means of reference. I have given examples of certain units which may be assumed; for instance, volt and ampere. From these all the other units will follow. I have assumed one volt to mean 1oz. driving at a radius of 1in., and one ampere one revolution per second. A coulomb is equivalent to one revolution; there is a farad when it makes one revolution with 1oz. of pressure; a henry, if you have a current of one ampere gradually reduced during one second of time by its own self-induction to zero. The pressure that is in that interval of time being constantly exerted is the equivalent of one volt—and that is obtained by the momentum of a cylinder of 1in. radius weighing 62oz. That is all I need say about that at the present time. Of course, these units might be varied, and when we are dealing with submarine cables we will take very different ones from these. On the other hand, we might take, for instance, an ampere to be 300 revolutions per second. So, when we are dealing with transmission of power from one place to another, if we wanted to make an analogy we would use other units from these. In each particular case we select our own units.

The primary discovery in electromagnetics was made by Oersted in 1820, when he showed that an electric current would deflect a magnet. From that simple experiment the philosopher might have retired to his chamber and worked out the whole of the electromagnetic phenomena which we are at present acquainted with. He could have seen that the north pole tends to rotate round the wire carrying a current in one direction and the south in another. He would have foreseen Faraday's experiment, in which a pole was made to rotate; he would have seen that in producing this mechanical action some power was used, and therefore the current was diminished and a counter E.M.F. set up in the wires; he would have seen that a wire acted as a magnet, and would consequently, when properly wound round a core, induce magnetism in a piece of soft iron.

But of all these different phenomena, the one I wish to direct your attention to most to-day is the work of Faraday. I have got to show it in its crudest and most simple and elementary form. I have here (Fig. 14) a single wire, which I shall connect with a battery through which I can suddenly send an electric current. In its neighbourhood, but not touching it, I have another wire which is not connected with any battery, but is connected with the galvanometer at the far end of the room. What I wish to show you is that at the moment of making an electrical contact

* Lecture delivered before the Royal Institution.

Digitized by Google

with the one wire, a current in the opposite direction is generated in the second one, and on breaking it a current in the same direction as the primary current is created ; that is to say, we ought to get a deflection of the galvanometer connected with the wire in one direction when we make the circuit, and in the other direction when we break it. Remember the galvanometer shows a current generated in the wire which has no battery connected with it.

Now, this phenomenon of induction is somewhat equivalent to momentum ; it may be considered as the equivalent of momentum. It sets up a counter E.M.F. in the wire through which the electric current is sent. It is just like the effect produced when we set a mass in motion—there is at first an opposition to its motion, and that is due to its momentum, and is a good analogue of the induced current.

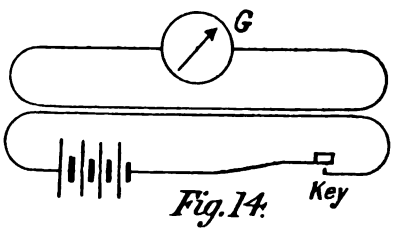


Fig. 14.

Now, you will see we have a spot of light upon the screen perfectly steady. I will send a positive current in one direction through one wire, and the spot of light, which indicates the current which goes through the other wire, is deflected to the right. I will now break the current, and the spot of light goes in the opposite direction, showing the current is induced in the opposite direction when we break the circuit. Now, a certain amount of power is being generated in the second wire, which is, of course, being taken out of the primary wire, through which the current is going—that is to say, momentarily the E.M.F. is acting against the current in the primary wire. That I have said is analogous to momentum. For example, here (Fig. 19) I have a rod with a heavy flywheel at the base of it. If I try to give a rotation to it with my finger there is at first an opposition to the motion—there is a sensible opposition, and it takes some little time to acquire the steady rotary motion which it eventually obtains. That resistance which my finger experiences is the counter E.M.F. But once I have started the thing, and it has acquired a steady rotation, there is no such counter E.M.F. acting at all. If I try to stop it I feel the effect of the flywheel trying to pull my finger round, and trying to continue its motion in the same direction. That gives us a clear idea of the self-induction that is taking place.

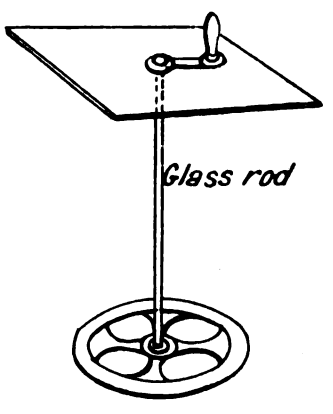

Fig. 19.

The application of these experiments and phenomena really belongs to great engineering works. In these we have frequently to do with alternating currents instead of continuous, and you will be able to see by the analogy that we have the induction of thecurrent producing a very remarkable difference in its effects in the two cases. After I have once got the flywheel started by applying a very slight force at the top, the flywheel has nothing to do with the rotation. But now suppose I try to produce an alternating current with the same force backwards and forwards. I find that I am not able to get up the same velocity, that the momentum of the flywheel interferes most materially with the freedom of rotation, and I am not able to get the same speed or the same current through my circuit by that means as I did with the continuous current. That that is the case I am going to show you very simply by means of a lamp, which is a very good indicator of the strength of a current. I have here a coil of wire, which is really a Gramme ring, and I will pass a current of electricity through this coil of wire and then through the lamp, Fig. 15. First, I will use a continuous current, and show you that the lamp at once acquires its full brightness. I will then use an alternating current, and show that the behaviour is very different, because here in the self-induction of this coil we have the momentum of the current acting in the same way as the momentum of the flywheel that I showed you. We will now try a continuous current. Now the current is simply passing through the resistance and through the lamp, and being a continuous current, there is no self-induction and no counter E.M.F. generated. Consequently, when I short-circuit the coil you see no perceptible diminution in the light of the lamp. The resistance of that coil, then, is very slight indeed, and produces no effect. I will now put on an alternating current. I cut out the self-induction coil, and I have now the alternating current passing through the lamp directly, and you see it gives the same brightness as with the continuous current—using 100 volts as I did before. I will now cut out this short-circuit and allow the current not only to pass through the lamp, but also to pass through the self-induction coil acting as the flywheel to which we are trying to give oscillating movements, and the lamp is immediately greatly diminished in brilliancy, as the effect of the reduction in the current produced by the coil.

Now, one of the greatest helps given to electrical engineering by the discoveries of Faraday has been the invention of the induction coil, or, as it is sometimes now called, the transformer. This can only be used with alternating currents. I have a specimen of a transformer on the table here. It consists of a core, of a bundle of iron wires, through the centre, with a coil of wire wound round it ; around that again there is a separate coil of wire, and presently I shall show you that when we change the strength of the current in the one wire a current is generated in the other wire. In fact, the transformer gives really a magnified effect of the induction of two wires upon each other. That

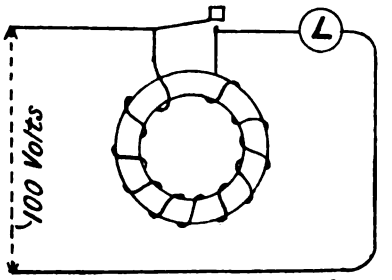

Fig. 15.

we were only able to detect by means of the galvanometer. The action of the transformer is much more powerful. The iron core is introduced, and instead of having a single wire, a number of coils are wound round, and that increases the effect to a great extent. The transformer has been of much use to electric light engineers in the past, because it enables us to convert a current of one pressure into a current of another pressure. If we have a large number of turns of wire on one of these coils, and a small number on the other, we may convert a high-pressure current into a low-pressure current, or *vice versâ*. That has been of great use in electric light engineering, enabling us to carry a high-pressure current to great distances over a thin wire, and to transform it at the point of consumption, where the consumers of electric light were pleased to transform the current to one of low pressure, such as is suitable for electric lamps and perfectly safe to handle.

But if that has been of use in electric light engineering, it has been infinitely more useful in electromotive power distribution. When I first had to investigate the problem of transmitting power from a power station at the Niagara Falls to different consumers who might be near at hand or far away, the first thing that struck me was the enormous difference in the character of the electric currents that different people wanted. Some people wanted it for lighting, some wanted it for power, some wanted it to generate electric currents for electrolytic operations ; some wanted continuous currents and some wanted alternating ; some wanted 100 volts and some 50 volts. I do not say that it would have been impossible to have supplied these demands by means of a continuous current, but there would have been very great difficulty in doing so, and in every single case it would have been necessary to introduce a motor driving a dynamo. The expense and the trouble of such a distribution would have been simply enormous. And although some very high authorities—I may mention Lord Kelvin among others, he almost alone now—persistently said that the continuous current would have been the best for the purpose, I am glad to say that in that great work the alternating current has been used, and it is a matter for congratulation to everybody concerned that the further we proceed with the work the more we see its adaptability to all the different circumstances that arise.

Now, with regard to this mutual induction which takes place in the transformer, I am going to show you the effect in a more striking way than by using the alternating current. I am going to show you that with the continuous current when you break the one circuit you are able to get a very powerful E.M.F. in

Digitized by Google

the other circuit. I shall pass a continuous current at 100 volts through the fine coil of this transformer, Fig. 16 ; I shall then break the circuit suddenly, and you will be able to see that, at the moment of breaking, an induced current is created in the secondary coil which will be sufficient to light up the lamp in circuit with it. I will first show you this without producing any effect—that is, with the electromagnet unexcited. I have now closed the primary circuit, and when I break the circuit it will not be sufficient to light the lamp. The counter E.M.F. is not sufficient to light that lamp, although I break this circuit as sharply as possible. The reason is that an arc is formed, as you perceive, where I break the circuit. This putting in of a graduated resistance which prevents a sudden break to the circuit causes the break in the circuit to be gradual and slow, whereas it is the suddenness of the break that causes the illumination of the lamp.

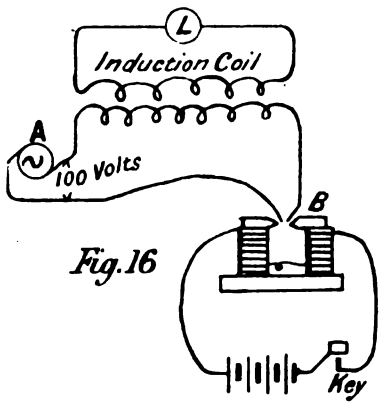

Fig. 16

I will now excite the electromagnet, and you will see that when I break the circuit at a point between the poles of the electromagnet, the electromagnet will not allow an arc of light to remain. The tendency is for the current of electricity to be deflected. That arc of light is the current of electricity, and the arc will be blown out almost instantaneously, and this enables me to get a sudden break instead of the gradual break which I had before. Now I have made the contact, and as soon as I break it you will notice that a much sharper spark is produced than before, that the lamp now lights up brilliantly ; and by having a very powerful magnet it is possible to produce a very sudden break indeed, and consequently a high E.M.F. in the secondary circuit.

(To be continued.)

THE SELECT COMMITTEE ON TELEPHONY.

The Committee of the House of Commons which is considering the sufficiency of the telephone service sat again on Friday last, Mr. A. Morley presiding.

The first witness taken was **Mr. Provand, M.P.**, who complained of the increase which he contended would be made in the trunk wire rates by the Post Office under the arrangement entered into with the National Telephone Company. In many cases the charge made by the Post Office was twice as much as that made by the company. Telephone users would be in a worse position under the new arrangements than they were at present, as the trunk wire rates that would be charged by the Post Office were higher than the rates now charged by the company. He further contended that the public interest had not been properly safeguarded under the agreement with the telephone company, and that it handed over to the company privileges which they ought not to possess. A charge for terminals was, in his opinion, altogether unjustifiable, and would be found to be very oppressive.

Mr. W. H. Preece, chief electrician to the Post Office, subsequently gave evidence explaining in detail the construction and the working of the telephone and the improvements that have been made of late years.

The committee then adjourned until Tuesday, when **Mr. Preece**, continuing his evidence on behalf of the Department, spoke in the highest terms of the automatic signals in operation in the United States in connection with the exchanges, which had a great advantage in preventing the confusion which the lack of these signals caused in this country.

Sir James Ferguson asked witness a question implying that it was impossible to adopt a similar system here.

Mr. Preece said the word "impossible" did not exist in his vocabulary. Mr. Preece proceeded to give his reasons against the municipalisation of the telephones. He explained that he thought it inexpedient that a town council should have control of a growing, speculative, and competitive industry like the telephones, which could only be maintained in a state of high efficiency when the service pays. An active opposition on the part of the National Telephone Company, who were not dependent for their success upon one local centre, could easily prevent a local success on the part of the town council. Again, financial failure and a constant call upon the rates would speedily raise the opposition of the class of ratepayers who did not use the telephone, and who were the masters of the situation. Further, high efficiency depended upon skilled labour and efficient supervision, and small local bodies could not afford to pay the high salaries that would command efficiency. In small municipalities not managed by skilled men the service must be defective.

After some further evidence, the committee adjourned.

ELECTRIC LIGHTING PROVISIONAL ORDERS.

Returns have been made to the House of Commons stating the nature of the proposals contained in the Electric Lighting Provisional Orders (No. 1) Bill, (No. 2) Bill, and (No. 3) Bill.

MOTHERWELL ELECTRIC LIGHTING ORDER, 1895.—The undertakers under this order are the Commissioners of the burgh of Motherwell. The area of supply is the burgh of Motherwell. The order contains provisions that the Commissioners shall lay down mains in certain specified streets within a period of two years, and it provides for the supply of electrical energy in the remainder of the area on certain specified conditions. The order also contains provisions (1) for the approval by the Board of Trade of the system upon which energy is to be supplied, and the issue by them of regulations for securing the safety of the public, and for ensuring a proper and sufficient supply of energy ; (2) for the execution of the necessary works and the breaking up of streets, etc., and the alteration of pipes, etc., under streets ; (3) for regulating the manner in which energy is to be charged for, and fixing the maximum price to be charged ; (4) for the appointment, remuneration, and duties of electric inspectors, and the testing of electric lines and other works, and for holding enquiries by the Board of Trade as to the causes of accidents affecting the public safety ; (5) for the supply, use, certifying, inspection, etc., of meters ; (6) for the application of moneys received by the undertakers in respect of the undertaking ; (7) for the transfer to any company or person of the powers, duties, and liabilities of the Commissioners under the order by means of a deed to be approved by the Board of Trade, upon such terms and subject to such exceptions and modification (if any), and for such period as may be specified therein ; (8) for the revocation of the order under certain circumstances.

STIRLING ELECTRIC LIGHTING ORDER, 1895.—The undertakers are the Commissioners of the burgh of Stirling. The area of supply is the parliamentary burgh of Stirling. The order contains provisions similar to those referred to in the case of the previous order.

ALDERLEY EDGE LIGHTING ORDER, 1895.—The undertakers under this order are the District Council of Alderley Edge. The area of supply is the urban district of Alderley Edge. The order contains provisions similar to those above.

LEIGH ELECTRIC LIGHTING ORDER, 1895.—The undertakers are the District Council of Leigh. The area of supply is the urban district of Leigh. The order contains provisions similar to those above.

LLANDUDNO ELECTRIC LIGHTING ORDER, 1895.—The undertakers are the District Council of Llandudno. The area of supply is the urban district of Llandudno. The order contains similar provisions to those above.

LUTON CORPORATION ELECTRIC LIGHTING ORDER, 1895.—The undertakers are the Corporation of Luton. The area of supply is the borough of Luton. The order contains similar provisions to those above.

RADCLIFFE ELECTRIC LIGHTING ORDER, 1895.—The undertakers are the District Council of Radcliffe. The area of supply is the urban district of Radcliffe. The order contains similar provisions to those above.

SWINDON NEW TOWN ELECTRIC LIGHTING ORDER, 1895.—The undertakers are the District Council of Swindon New Town. The area of supply is the urban district of Swindon New Town. The order contains similar provisions to those above.

CARLISLE CORPORATION ELECTRIC LIGHTING ORDER, 1895.—The undertakers under this order are the Corporation of Carlisle. The area of supply is the city and municipal borough of Carlisle. Similar provisions are contained as in the foregoing.

PONTYPOOL ELECTRIC LIGHTING ORDER, 1895.—The undertakers are the Pontypool Electric Light and Power Company, Limited. The area of supply is the urban district of Pontypool. The order also provides for the revocation of the Pontypool Electric Lighting License, 1893.

WALTHAMSTOW ELECTRIC LIGHTING ORDER, 1895.—The undertakers are the District Council of Walthamstow. The area of supply is the urban district of Walthamstow.

WINCHESTER ELECTRIC LIGHTING ORDER, 1895.—The undertakers are the Corporation of Winchester. The area of supply is the city of Winchester.

WORTHING ELECTRIC LIGHTING ORDER, 1895.—The undertakers are the Corporation of Worthing. The area of supply is the borough of Worthing.

LEGAL INTELLIGENCE.

PROELL GEAR.

On Wednesday there came before the Judicial Committee of the Privy Council (present — Lord Watson, Lord Hobhouse,

Digitized by Google

Lord Morris, Lord Davey, and Sir Richard Couch) the case of Carl Pieper's patent. It was a petition for the prolongation of letters patent granted to Carl Pieper, civil engineer and patent agent, Berlin, for an invention of "certain improvements in the expansion gear of steam-engines," a communication from Dr. Wilhelm Rudolph Proell, of Dresden, bearing date May 12, 1881, and numbered 2,069.

Mr. A. J. Walter and Mr. Fearnley Owen were counsel for the petitioners; the Attorney-General and Mr. Sutton for the Crown.

The invention for which the letters patent were granted consisted in an improved liberating expansion gear—namely, a mechanism in which the parts of an engine serving to transmit motion from the eccentric to the admission or expansion valve were disengaged from each other in a novel manner at a certain point of each stroke under the control of the governor. It was stated that the chief merit of the invention lay in the fact that automatic variable expansion could by its application be secured with the fewest possible parts, which admitted of a very compact construction, and the use of the invention had rendered it possible to apply the principle of automatic variable expansion to existing steam-engines without the necessity of removing the cylinder of the engine and replacing it with a new one, as would have been formerly necessary. The invention could not only be applied to slide valves but also to double-beat valves; and for the purposes of obtaining the full advantage of the system of automatic variable expansion double-beat valves were to be preferred. Dr. Proell in 1881 also obtained grants of letters patent for his invention in Germany, Austria-Hungary, and France, all of which foreign patents had now expired. In 1883 Dr. Proell appointed Dr. Hermann Kühne his agent in this country for the purpose of pushing the invention here, upon the terms that Dr. Kühne should receive one-half of the royalties received from the use of the invention. In 1886 the letters patent were by direction of Dr. Proell assigned to Dr. Khüne, the equitable estate in them being vested in Dr. Proell. On September 4, 1892, Dr. Proell died, and the equitable estate in the letters patent since that date had been and was now vested in his widow, the legal estate in them being vested in Dr. Khüne. Owing, it was stated, to the great indifference which the invention met with in this country at its first introduction, the gross receipts during the earlier years were wholly inadequate. The great utility of the invention was now being generally recognised, and it was only now, when the letters patent were about to expire, that the use of the invention was becoming fully established and extending. The petitioners had no doubt that if the term of the letters patent should be extended the letters patent would become productive, and the petitioners would be able to obtain a fair reimbursement and remuneration commensurate with the public value and importance of the invention. The gross amount of the royalties received in England in respect of the invention was £7,986.

The **Attorney-General**, on the part of the Crown, admitted that the invention was one of merit.

Mr. Sutton said the Crown desired to leave the matter in their Lordships' hands. He addressed their Lordships on the question of the amount of remuneration received.

A number of witnesses was called in support of the petition, and gave evidence testifying to the merit of the invention, one of the advantages arising from the use of which was the great reduction which it effected in the consumption of fuel.

Lord Watson, in delivering their Lordships' judgment, said that in this case their Lordships were invited to grant an order for which, as far as they were aware, there was no precedent—and none had been stated by counsel at the Bar. The patent sought to be prolonged was one of four—three of which were issued in continental countries, the last of which expired two years ago, since which date the patent in question had still been current, and her Majesty's subjects exposed to some degree of prejudice which was not occasioned to the inhabitants of any other country. Their Lordships were not prepared to say that in these circumstances there could be no renewal of the patent, but they were certainly prepared to go this length, that the circumstance of its being the last patent—the sole survivor—was in these circumstances a great obstacle to granting a renewal. It would require very strong grounds to warrant the renewal of the patent in these circumstances, and their Lordships had not been able to find any grounds to warrant them in doing so, although they were quite prepared to hold that the patent had sufficient merit to warrant a prolongation in favourable circumstances. Their Lordships refused the application.—*The Times*.

IN RE THE MERSEY RAILWAY COMPANY.

An application has been made in the High Court of Justice by the receivers and managers for leave to spend a sum of about £800 in promoting a Bill in Parliament with the object of conferring upon the company power to work their railway by electricity in lieu of steam. The summons was heard in chambers, but his Lordship gave judgment this morning in court.

Mr. Butcher appeared for the applicants; Mr. Theobald for the first debenture stock holders supported, and Mr. E. Ford for the second debenture stock holders opposed the summons. Mr. R. J. Norton represented the company.

Mr. Justice Stirling said that the question was whether the money in the hands of the receivers could be thus applied under Section 4 of the Railway Companies Act, 1867. It did not appear to come within "working expenses" of the railway or other proper outgoings in respect of the undertaking. It was an application to Parliament to vary the mode of carrying on the business of the company. Neither was it in the nature of salvage. If all the parties had been agreed, his Lordship might have been inclined to accede to the application. It seemed probable that it might help the business of the company, but it was a speculation, and his Lordship could not allow any part of the fund in court to be applied for that purpose.

COMPANIES' MEETINGS AND REPORTS.

SUBMARINE CABLES TRUST.

On Friday last Sir John Pender, M.P., presided at the twenty-fourth annual meeting of certificate-holders of the Submarine Cables Trust, held in the Board-room at Winchester House.

The **Chairman**, in moving the adoption of the report, said the revenue for the past year amounted to £21,464, as against £22,592 for the previous year, or a decrease of £1,128. This was owing to their having received a smaller dividend for the current year in the Anglo-American Company. The expenses of the Trust for the year amounted to £1,194, as against £1,501 for last year. The total expenses, however, were £805 less than the amount provided by the trust deed. The revenue for the year had enabled them to meet two coupons of £3; but they had not been able to pay anything off the remaining portion of the overdue coupons. There was, therefore, still a balance of £15 in arrear, but this, they anticipated, would be paid about the middle of July next. The present market value of the investments held by the Trust over cost price showed an increase of over 52 per cent.

Mr. Kenneth L. M. Anderson seconded, and the motion was carried.

The **Chairman** remarked that while telegraphs flourished the Trust would continue to flourish.

MORECAMBE ELECTRIC LIGHT AND POWER COMPANY, LIMITED.

The fourth annual meeting of shareholders has been held at Morecambe, the proceedings being conducted in private. Mr. C. M. Mabbott, chairman of the Company, presided.

The report showed a loss of £424. 14s. 5d., mainly due to loss on supply of current consequent on the "scale system" of annual charges per lamp being found unremunerative. This had been a serious mistake, and would be abandoned forthwith in favour of supply by meter. Law costs and fine for nuisance accounted for £48. 12s. 8d. The conviction for nuisance had necessitated the removal of the premises to a non-residential part of the town, and for this it was proposed to raise £1,800 of preferential capital. The report and balance-sheet were adopted.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Birkenhead.—The Corporation invite tenders by 23rd inst. for boilers, engines, dynamos, etc. Particulars are given in our advertisement columns.

Edinburgh.—Contractors willing to do electric wiring and fitting to specification in Edinburgh are requested to communicate with Prof. George Forbes, 34, Great George-street, Westminster.

London, E.C.—Among stores for which the Great Eastern Railway Company invite tenders by May 16 are (17) telegraph materials, and (19) leather and indiarubber. Forms of tender can be obtained at the secretary's office, Liverpool-street Terminus, E.C.

Burton-on-Trent.—Tenders are invited for the supply of 25,000 tons, or a portion thereof, of best screened gas coal, for the Town Council. Forms of tender and conditions of supply may be obtained upon application to Mr. F. L. Ramsden, manager and engineer, Gas and Electric Light Works, Wetmore road, Burton-upon-Trent, and sealed tenders, endorsed "Coal," are to be delivered to the manager at or before 10 a.m. on 25th inst.

Tunbridge Wells.—Tenders are invited by the Corporation for the wiring of the Municipal Buildings in accordance with the specification prepared by the electrical engineer. Copies of the specification may be obtained from Mr. W. C. Cripps, town clerk, Town Hall, Tunbridge Wells, on payment of a deposit of £1, which sum will be returned on receipt of a bona fide tender. The buildings can be inspected at any time. Tenders, endorsed "Electric Light," must be sent to the town clerk by 28th inst.

Brighton.—Notice is given that the Council of the borough will receive tenders from such persons as may be willing to enter into a contract for the supply and erection of boilers at the Corporation electricity works. The Council also want tenders for the supply and erection of arc lamps, switches, etc., and, thirdly, for the supply of indiarubber lead-covered armoured cables. Specifications can be obtained on application at the town clerk's office, Town Hall, Brighton. Tenders for the boilers are to be sent in by May 13; for the arc lamps, switches, etc., by May 27; and for the indiarubber lead-covered armoured cables by May 13.

Rangoon.—Tenders will be received by the president of the Rangoon Municipal Committee, not later than November 4, for the lighting of Rangoon by electricity. Tenders should be accompanied by detailed plans, specifications, and estimates, and must state the terms on which the installation proposed will be under-

Digitized by Google

taken. All information regarding the existing system of lighting and the cost, etc., with plan of the town, can be obtained on application to Messrs. Ogilvy, Gillanders, and Co., Sun-court, 67, Cornhill, London, E.C., accompanied by a remittance of £1. 1s. Tenders are to be sent in sealed covers and endorsed "Tender for Electric Lighting, Rangoon." Mr. J. Short, Rangoon, is the secretary of the committee.

Manchester.—The Corporation invite tenders for the supply, delivery, and erection, complete, of the electric lighting machinery and installation for the efficient lighting of the new foreign animals wharf, situated at Mode Wheel. Copies of general conditions, specification, and drawing can be obtained on application to Mr. T. de Courcy Meade, city surveyor, Town Hall, Manchester, on payment of five guineas (which will be returned on receipt of a *bonâ fide* tender). Tenders, to be endorsed "Tender for Electric Lighting, etc., Foreign Animals Wharf, Mode Wheel," to be addressed to the chairman of the Markets Committee, and delivered at the city surveyor's office not later than 9 a.m. on Monday, May 13 The Corporation do not bind themselves to accept the lowest or any tender.

Shoreditch.—The Vestry invite tenders for the erection of a dust destructor, 12 furnaces, flues, boilers, and accessories, to be guaranteed capable of dealing with about 20,000 tons of refuse per annum and of producing the amount of steam stated in the specification for electric lighting and other purposes. A formal contract to be entered into under seal, with sufficient sureties, to secure such guarantee. Forms of specification and sketch plan, with further information, may be obtained from Messrs. Kincaid, Waller, and Manville, the engineers, of 29, Great George-street, Westminster, S.W., on payment of £3. 3s., which will be returned to persons tendering on a bona fide tender being received by the Vestry. Sealed tenders must be sent to the vestry clerk, endorsed "Tender for Dust Destructor, etc.," by Monday, May 20, or by such extended period as may be specially allowed to any intending contractors upon application to the engineers; and contractors, or their representatives, must attend at the Town Hall, Old-street, E.C., at 6 p.m. on the same date, when the tenders will be considered by the committee. Trade union rates of wages and hours must be observed by contractors.

BUSINESS NOTES.

Derby.—The electric lighting of the market hall has been completed.

Great Northern Telegraph Company.—For the month of April the receipts were £27,600.

Burton-on-Trent.—There was a loss last year on the Corporation electric light station of £1,800.

Blackburn.—The cost of all the electric lamp-posts which have been erected in the town is £240. 16s.

Fairfield (Buxton).—The Urban District Council have appointed an Electric Lighting Committee.

Tottenham.—The District Council have referred the question of electric lighting to the General Purposes Committee.

Direct Spanish Telegraph Company.—For the month of April the receipts were £1,942, as against £1,742 for the same period of 1894.

Eastern Telegraph Company.—The receipts for the month of April were £67,046, as against £56,751 for the corresponding period of 1894.

South London.—The Board of Trade announce that the Battersea and Newington provisional electric lighting orders will not be proceeded with.

West India and Panama Telegraph Company.—The receipts for the two weeks ended April 30 were £106 more than for the corresponding period of 1894.

Eastern Extension Telegraph Company.—For the month of April the receipts show a decrease of £722 as compared with the corresponding period of 1894.

South Staffordshire Trams.—The Board of Trade have granted a further extension of the license for the use of steam on the South Staffordshire tramways until May 15.

Aden.—The sum of Rs.20,500 has been provided in the current estimates for the maintenance of electrical communications in connection with the defence works at Aden.

London Platino-Brazilian Telegraph Company.—The ordinary general meeting was held on Monday at Blomfield House, London-wall. The proceedings were not open to the Press.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 5th inst. amounted to £1,148, as compared with £874 in the corresponding week of last year.

Eccles.—The engineer of the sewage farm works has reported to the Town Council that the contractors for the electric light installation have commenced the wiring of the manager's house.

Madras.—The consulting engineer to the Indian Government for railways has reported that there is no impediment to the Madras electric tramway being opened for public traffic, and that no danger will attend its use.

Stourport.—A meeting of the Urban District Council has been held at which, on the motion of the chairman (Mr. C. K. Harrison) seconded by Mr. Beakbane, the Council approved of the proposal to connect Kidderminster with Stourport by the suggested electric tramway.

Wimbledon.—At the last meeting of the District Council the Road and Drainage Committee reported that the question of electric lighting had been fully discussed, and that Mr. W. H. Preece had (as we have already announced) been instructed to make a report.

Cardiff.—The Lighting Committee of the Town Council have recommended the borrowing of £1,860 for the extension of the electric light mains to Guildford-street baths and down Newport-road as far as Castle-road and up West-grove. The Corporation will consider the matter.

Kendal.—The Town Council have held a meeting at which a resolution passed by the Chamber of Commerce was read, asking the Council to consider the question of supplying the town with electricity for power purposes, and it was agreed to reply that the matter was engaging the attention of the Corporation.

City and South London Railway.—The receipts of the Company for the week ended May 5 were £864, against £887 for the corresponding week of 1894, or a decrease of £23. The total receipts for the current period of the present half-year are £16,983 against £16,401 in the corresponding period of 1894, an increase of £582

Cowes.—A meeting of the District Council has been held, at which the Water and Lighting Committee's minutes stated that the surveyor having reported on the result of the canvass *re* electric lighting, they had decided to recommend the Council to obtain the opinion of an expert on the plans of the surveyor as to this mode of lighting as early as possible. This proposal was approved of by the Council.

St. Pancras.—The Vestry have agreed to lay an electric main from University-street, along Gower-street, to the parish boundary at a cost of about £214. The Electrical Committee have been instructed to consider the question of extending the mains along Highgate-road and West-hill. The tender of Mr. James Steed, of 61, Chalk Farm-road, for £415. 8s. 5d., for building the sub-station in St. Andrew's-gardens, has been accepted.

Burnley.—Alderman Collinge said at a meeting of the Town Council that the Gas and Electric Lighting Committee had, on the recommendation of Mr. Thursfield, resolved that the engine driver and fireman of the electric lighting works should be allowed a week's holiday in the summer and have their wages paid. Both of these men were fully occupied the year round, Sundays included, and got no holiday whatever. The minutes were passed.

Liverpool.—The usual weekly meeting of the Lighting Committee of the Corporation was held on Monday at the municipal offices, Alderman F. Smith presiding. There was no further consideration of the proposed purchase by the Corporation of the Electric Supply Company's undertaking, it being understood that the report was being awaited of Sir Frederick Bramwell in regard to the business carried on by the electric supply company.

Electric Cooking Apparatus.—Messrs. Crompton and Co., Limited, send us from their Brompton-road branch an illustrated price-list of electrical heating and cooking apparatus. The list includes ovens, hot-plates, kettles, frypans, saucepans, urns, sealing-wax heaters, cigar lighters, irons (flat and otherwise) and radiators. An interesting pamphlet on cooking by electricity has also been issued by Mr. H. J. Dowsing, of Messrs. Crompton and Co.'s firm.

Cupar (Fife).—At a meeting of the Fife County Road Board in Cupar, Mr. Haig, of Ramornie, submitted the sub-committee's report on telephones, and it was agreed to give powers to the committee to make a fair and reasonable agreement with the telephone company on the basis of getting 2s. 6d. per mile of wire for wayleave, and as much accommodation as possible from the company in the way of free telephone instruments at several of the police offices in the county.

Fulham.—The Vestry have held a meeting, at which Mr. W. R. Sayer proposed that a special committee of 15 should be appointed to consider and report as to the advisability of applying for a provisional order to supply the electric light to the parish, also as to constructing a destructor in connection therewith. This was carried. The Lighting Committee have also appointed a special sub-committee to consider the question of lighting the Town Hall by electricity and the cost thereof.

Grantham.—The Estates Committee have reported to the Town Council that, after considering an application made by Messrs. Martin and Fitt, of High-street, asking to be allowed to carry light cables across the streets of the borough for the supply of electric light, they did not see their way clear to recommend the Council to grant to Messrs. Martin and Fitt a general license for the above purpose, but they were prepared to deal with each separate application on its merits.

Dover.—The Dover Council have met, when, in reply to Councillor Fry, who said the lamps were lighted at 7.40, the Town Clerk stated that every light ought to be turned on at sunset. The town clerk was ordered to write to the company calling their attention to this fact, and the police were ordered to include the lights in their nightly reports on the lighting. A letter was also read from the Board of Trade stating that they were unable to send one of their inspectors to inspect the works.

Electric Lighting Extension in London.—The Board of Trade have decided to grant a provisional order to the County of London and Brush Provincial Electric Lighting Company, Limited, for power to supply electricity within the district of the St. Olave's Board of Works. The Board have also granted a provisional order to the Charing Cross and Strand Electricity Supply Corporation, Limited, for the electric lighting of the district within the jurisdiction of the Strand District Board of Works.

Digitized by Google

Chiswick.—The clerk to the District Council at the last meeting of that body read a letter from Mr. Watts, of Devonhurst, Duke's-avenue, asking when the electric lighting scheme for Chiswick was likely to be completed, as he was having certain alterations made to his house, and desired to have electric light fittings fixed. The Clerk intimated that he had replied to the effect that it was hoped that the electric light would very shortly be available. The Surveyor said the company hoped to have the mains laid in a month.

Cheltenham.—According to the minutes of the Electric Lighting Committee of the Town Council, Mr. Preece has expressed his willingness to come to Cheltenham to take part in the inauguration of the lighting by the Corporation on Thursday next. It was resolved that Prof. Ayrton, F.R.S., Mr. A. Siemens, and Mr. Callender be invited to the opening. Baron de Ferrieres wrote suggesting that an arc lamp on a tall post should be placed at the junction of the Colonnade and High-street, and it was resolved to adjourn the matter for further consideration.

Electric Launch.—An experimental test of the recently invented Clydebank electric primary battery took place this week on the Clyde at Glasgow, says the *Scotsman*. Four sets of batteries were placed in a small boat 16ft. long, and these were connected with a small motor fixed in the centre of the little vessel. The batteries weighed over 1cwt., and each cell—there being 12 cells in a battery—measured 8in. by 3in. by 3in. The boat went at the rate of about six miles an hour. Messrs. R. and A. Macdonald, Clydebank, are the inventors.

City and South London Railway Bill.—Lord Morley's Committee of the House of Lords on Monday passed the Bill which grants to the City and South London Railway Company an extension of time for three years within which to construct the authorised extension of their electric railway from Stockwell to Clapham Common. The Bill also empowers the company to raise £30,000 additional ordinary or preference capital. and to borrow a further sum of £10,000 by the creation of debenture stock. This Bill has now been sanctioned by both Houses.

Western and Brazilian Telegraph Company.—For the past week the receipts were £2,891. The directors of the Company, subject to final audit, have decided, after placing £8,000 to the reserve fund and £5,000 to the debenture redemption fund, to recommend the payment of 6s. per share, free of income tax, making, with the interim dividend paid in November, a total distribution of £3 per cent. for the 12 months ending December 31. This will give 6s. to the ordinary, 4s. 6d. to the preferred ordinary, and 1s. 6d. to the deferred ordinary shareholders.

Belfast.—The report of the Electric Committee of the Corporation presented at the last meeting of the latter body contained the following: "With a view to encourage the 'daylight' consumption of electric current, your committee have fixed the charge for electricity used for heating, motor, and purposes other than lighting during the daytime at 4d. per unit, with discounts, and if this be taken advantage of to any appreciable extent it may lead to a reduction in the charge made for lighting purposes." On the motion of Alderman Pirrie, seconded by Alderman Lawther, the report was adopted.

Gold Medal.—Messrs Crompton and Co., Limited, have just been awarded a diploma and gold medal at the Universal Food and Cookery Exhibition now being held at the Portman Rooms. This is the fifth diploma and fourth gold medal obtained by Messrs. Crompton and Co. since they started the manufacture of electrical heating and cooking apparatus about two years ago. The awards in each case have been made by experts in the particular business concerned, and the samples of food being cooked daily in the electric oven are pronounced by those most competent to give an opinion to be the "perfection of cookery."

Worcester.—Mr. Ruthven Murray having been appointed to take charge of the electricity works, the Streets and Water Committees of the Town Council recommend that Mr. Caink be relieved of the duties delegated to him so far as they relate to those works, and that his salary be reduced to £350 per annum, on the understanding that it be increased by £10 per annum until £400 is reached. This is equivalent to an immediate reduction of £100 per annum. The Worcester Board of Guardians have decided to accept the tender of Mr. Santonna for the supply of fittings for the electric light installation in a portion of the workhouse.

Kingswood (Bristol).—The chairman of the Urban District Council has mentioned that the matter of the extension of the electric light had been under the consideration of the Works Committee, who recommended that for the present it be deferred. On the recommendation being adopted, the chairman further said that he had had a conversation with Superintendent Matthews, the result of which was that the police would for the future make a note and report on all lamps in the district that were not lighted. To facilitate this duty, it was resolved to ask the electrical syndicate to number all the lamp-posts at Kingswood and Hanham.

Brazilian Submarine Telegraph Company.—The report of the directors for the half-year ended December 31 last states that the revenue for this period amounted to £104,926. and the working expenses to £36,771. After providing £4,841 for debenture interest and sinking funds and £1,490 for income tax, there remains a balance of £61,822; to this is added the sum of £1,501 brought forward, making a total of £63,324. First and second interim dividends, amounting to £39,000, have been paid, and £20,000 transferred to the reserve fund, leaving the sum of £4,324 to be carried to the next account. The receipts for the half-year include the sum of £1,500 dividend to June 30 on the Company's shares in the African Direct Telegraph Company, Limited.

Brighton.—A special meeting of the Town Council was called for yesterday to consider the question of the tenders for the electric lighting station. At the previous meeting of the Town Council it was decided, despite some opposition, to accept the decision of the Works Committee in favour of Messrs. Longley and Co.'s tender for the extension of the electricity generating station, although the tender of Messrs. W. A. Field and Co. was nominally lower. The committee have, however, reconsidered the matter, and have come to the conclusion that Messrs. Field and Co. have made substantially the better offer. They therefore asked the sanction of the Council for giving the business to the Brighton firm.

Edinburgh.—On Tuesday a meeting of the Town Council was held, at which Mr. Douglas asked Bailie Steel when the Cleaning and Lighting Committee intended reporting on the motion by Bailie Gulland on the subject of lighting by electricity George-street and the other streets adjoining? Bailie Steel replied that the matter was lying over in the meantime. Mr. Cameron asked if the Electric Lighting Committee intended to refuse change over switches to owners of private plant, thus depriving them of the public light unless at great expense The town clerk read a telegram from Councillor Mackenzie, who was in London, to the following effect: "Committee advised by Prof Kennedy change-over switches dangerous; might cause accidents, and should not be sanctioned."

Bury.—A meeting of the Bury County Council was held on Thursday last week, at which Alderman Parks said the Electric Lighting Committee had had a meeting, but as they had not been able to formulate their report there were no minutes to submit to that meeting. It might, however, be necessary to have a special meeting before the next ordinary meeting of the Council. Councillor Barr expressed the opinion that the Gas Committee and the Electric Lighting Committee ought to work well together, and that there ought to be no antagonism between them. He thought the gas manager and the borough engineer should work hand-in-hand in this matter, and he also thought that there ought to be an exhibition in the centre of the town as to how gas and the electric light should be used.

Tunbridge Wells.—The Lighting Committee of the Council presented the report which we gave in our previous issue at the last meeting of the Town Council. Councillor Wood moved its adoption, pointing out that their machinery was sufficient for more lighting than they had applications for in the compulsory area. The money would only be spent as required, and the mains would only be extended as a fair return was shown. Councillor Gower asked if the present addition to capital would enable them to supply the whole town, and when the light would be commenced. Councillor Wood said they could expect the light in June, and on Mr. Preece's authority the proposed capital would be sufficient for the present population, and if they wanted more it would pay for itself. The report was adopted.

Hastings.—The Public Lighting Committee of the Town Council have had under consideration the matter of the desirability of improving the existing public lighting arrangements at the baths. By their instructions a sub-committee viewed the place, and reported that in their opinion additional light was much needed on the south side of the promenade, and in accordance with a suggestion made by them, the committee recommended that, subject to satisfactory arrangements being made with the electric light company, an electric lamp should be placed at the south-east corner of the approach to the ladies' bath, and another at the south-west corner of the approach to the gentlemen's bath, provided the necessary consent of the baths company to the fixing of the same in those positions could be obtained, such lamps to be kept lighted until midnight. The report has been adopted by the Town Council.

New Windsor.—Notice is given that the Board of Trade have issued a provisional order under the provisions of the Electric Lighting Acts, 1882 and 1888, with a view to the same being included in a confirmation Bill about to be introduced into Parliament, to the Mayor and Council of New Windsor, authorising them to supply electrical energy for all public and private purposes within the borough of New Windsor and the Eton urban district. Copies of the provisional order have been deposited for public inspection at the office of the clerk of the peace for the county of Berkshire at Reading, and with the clerk of the peace for the county of Buckingham at Aylesbury, at the office of the clerk to the Eton Urban District Council, and at the office of the town clerk of New Windsor. Printed copies of the same can be obtained at the offices of the last-named at the price of 1s. each.

Pokesdown (Hants).—An adjourned parish meeting has been held to consider whether the parish should adopt the Lighting and Watching Act of 1883. Mr. W. Bolton, the chairman of the meeting, said it would be a grand thing if they could light the whole of the neighbourhood by electricity. Mr. Freak then read an estimate received from Messrs. Bergtheil and Young, electrical engineers, London, in which they offered to light the district with 20 lamps for £730. That sum would include a dynamo, a gas-engine to drive it, and the necessary apparatus, switches, cable, posts, etc. In addition to that sum, Mr. Freak explained there would be the cost of fixing the plant, which he estimated at £150. That would bring the total cost to £880. The annual expense—such as carbons, engineer's salary, gas for engine, etc.—would be about £245. Ultimately the meeting was adjourned.

New Mains in London.—The County Council have approved of new electric light mains being laid by the Hampstead Vestry in Arkwright-road, Ellerdale-road, Prince Arthur-road, in and across

Digitized by Google

High-street to Gayton-road, Windsor-terrace, Belsize park and square, Lancaster place and road, and Strathray-gardens, Eton-avenue and England's-lane, Fortune Green-lane, Parsifal-road, and two portions of Finchley-road. The construction of a transformer-chamber under Finchley-road has been disapproved. Application has been received from the St. Pancras Vestry to lay mains in Gray's-inn-road and Wells-street. The proposed works were approved of, as were those of the Kensington and Knightsbridge Electric Lighting Company for laying mains in Hill-street, Knightsbridge The House-to-House Electric Light Supply Company intend to lay mains in Courtfield road and gardens and Collingham-road.

Portsmouth.—Mr. T. Codrington, Local Government Board inspector, has held an enquiry respecting applications to the Board from the Portsmouth Corporation to borrow, *inter alia*, £21,000 for extending the electric light. The application for this loan was supported by Mr. Alderman Ellis, chairman of the Electric Lighting Committee. He said that the light had already been so successful in the town that the income from the Corporation and private consumers had been sufficient to pay the interest and the sinking fund. There was a general outcry in the borough for an extension of the light beyond the present area, and the committee thought it desirable to make one loan to cover the cost of supplying the light to the main arteries of the borough. The mileage would be 8½, and 150 additional lamp-columns would be required. After supplying the public lamps there would still be enough power to supply 7,000 private lamps. There was no opposition.

Electric Haulage.—Messrs. Ernest Scott and Mountain, Limited, Close Works, Newcastle-on-Tyne, have secured the contract from the Huckleton Main Colliery Company, Thurnscoe, near Rotherham, for the electrical machinery in connection with a large endless-rope-haulage plant which they are fitting. The dynamo and motor are of Messrs. Scott and Mountain's improved type, and are capable of giving an output of 80,000 watts and 90 effective horse-power respectively. The plant is being so arranged that an additional dynamo and motor can be added as the colliery is opened out. The same firm are also busy with their new type of electrical fan, and have fans and motors of this description in hand for H.M.S.'s "Juno" and "Doris," and other vessels. These fans are being used in connection with the internal ventilation of ships, but Messrs. Scott and Mountain have made a considerable number of electrically-driven fans for induced and forced draught.

Birkenhead—A meeting of the Town Council has been held, at which the Finance Committee opened and considered tenders which had been received for the erection of the new chimney at the proposed electric central station, and recommended that the tender of Messrs. Holme and Green, of Liverpool, to execute the work for the sum of £850, be accepted, subject to certain conditions. Alderman Deakin moved the confirmation of the proceedings of the committee, and stated that Mr. Shoolbred, electrical engineer, assured them that he had already placed specifications before the Local Government Board, and that they had been approved by the technical specialists of the Department. He hoped if tenders in connection with the electric lighting scheme were accepted at the next meeting of the Council, he would be able to have a station ready for the supply of electric light by the month of September next. Mr. Gostenhofer seconded, and the proceedings were confirmed.

Extension of Business.—The Nalder and Harrison Construction Syndicate, Limited, of 47, Victoria-street, S.W., inform us that, owing to the large increase of business, and their intention to extend their field of manufacture, they have purchased the lease of the extensive premises known as the Invicta Works, Bow Common-lane, E., together with the complete efficient engineering plant and machinery in them, and that they will thus be enabled to carry out work of the very largest and heaviest description, in addition to their present output of electrical measuring and testing instruments, switchboards, etc. The syndicate intend to produce as soon as possible standard types of dynamos, motors, transformers, steam-engines, etc. As the work of transferring the existing plant at Trafalgar House and completing all new arrangements is of considerable magnitude, and one needing a certain length of time, it is the intention of the syndicate to keep the works at Trafalgar House open until the new ones are as nearly as possible complete, in order that there may be no unnecessary delay in the execution of orders. In the meantime all communications should be addressed to the head offices at Victoria-street.

The London Telephone Service.—The Clerk to the City Commission of Sewers on Tuesday read a circular which had been received from a committee of the London County Council asking the opinion of the citizens on the subject of the telephone service and its efficiency; whether it was efficient, or, if not, in what respects was it unsatisfactory. Mr. Pannell moved that the circular should be referred to the Streets Committee, with instructions to issue a similar circular to the citizens without delay. Mr. Alderman Bell objected to such information being filtered through a committee of the London County Council. Mr. Berridge said if the proposed course was adopted, the information would be obtained too late for it to be of any use. Mr. Wallace declared that the Commission of Sewers should be the mouthpiece of the citizens in so important a matter, and said when he received a circular similar to that read by the clerk he made up his mind not to allow the County Council to score off the Commission, which had a *locus standi* before the Select Committee. The largest users of telephones were in the City, and any information the citizens had to give should in his opinion come through that court, and not through the County Council. Mr. Pannell's motion was adopted.

Llandudno.—A syndicate has been formed for the purpose of obtaining an order authorising the construction of tramways in Llandudno and the districts of Colwyn Bay and Conway. The local authorities of the two latter districts have given their consent to the scheme, but the Llandudno District Council as a body have dissented from it, although as individuals many members favour the scheme. A vote of the inhabitants was taken some weeks ago as a preliminary test, but although it proved adverse the promoters believe that had all the voting papers been collected the result of the poll would have been in their favour. By Section 4 of the Tramways Act, 1870, the consent of the local authority is required where the promoters are not the local authority. The Board of Trade may make a provisional order authorising the construction of such tramway, if they are satisfied after enquiry that two-thirds of its length is proposed to be laid in the district or districts where the local authority or authorities do not consent thereto. In the present case the scheme, without the inclusion of Llandudno, cannot be proceeded with, and the promoters have therefore obtained counsel's opinion, which is decidedly in their favour. At a meeting of the promoters at Manchester, it was decided that a survey of the district should at once be taken.

Dowlais.—The annual meeting of the Dowlais Chamber of Trade was held last week, the president (Mr. J. King Price) occupying the chair. The Chamber having at a previous meeting decided to ask the Dowlais Gas Company for a reduction in the price of gas, seeing that the people pay 3s. 6d. per 1,000ft. as against 3s. 2d. paid in Merthyr, the secretary read a letter from the gas company declining to make a reduction. The President complained of the unfair way in which the tradesmen were treated by the gas company, and called attention to the fact that the Dowlais Iron Company were about to supply all their officials with the electric light. He thought it would put an end to the tyranny of the gas company if they could induce Mr. E. P. Martin to supply the tradespeople as well with the electric light. Mr. S. Makin said he should not like to see the town dependent for its light upon the works people. Mr. Morgan L. Walters said the gas company had but one object in view—namely, the highest dividend they could screw out of the people. He and many other speakers strongly urged a similar course to that pointed out by the chairman, but it was eventually decided that before approaching Mr. Martin the Chamber should make one last appeal to the gas company, and a deputation was appointed to wait upon them.

Keynsham.—A party has visited Keynsham and Kingswood, near Bristol, this week to examine Messrs. Parfitt's electric lighting system, upon which Prof. Silvanus P. Thompson has reported. He says "the system of Messrs. Parfitt is a system of series lighting applicable to incandescent lamps of various powers and sizes, and can be carried out either with overhead wires or with underground cables. Being a series system, it possesses the great advantage of economy in copper. It has also the incidental advantage that the most distant lamp, if of equal size, will work just as brightly as that nearest the station. The particular device, which is the essence of the system, and which is covered by Messrs. Parfitt's patent, is that of splitting each circuit of lamps into two cross-connected series, there being between each of the points of cross-connection two lamps which share the current between them, and two automatic devices. These devices, which are simple, inexpensive, and efficient, fulfil a double function—on the failure of any one lamp they immediately protect the second lamp in that section of the circuit from being over-run, and they protect the remaining lamps in the row from extinction. This mode of arranging and protecting a series circuit is, so far as I am aware, entirely novel, and I am satisfied that it is effective." The visit was in connection with the formation of a company to take up the patents.

Dublin.—The contract for the erection of the power station of the Southern Electric Tramway Company has been entrusted to Alderman Meade, who has already a numerous staff of hands at work in the initial proceedings. They will at first be engaged in the task of levelling off for laying the foundations of the power-house, which will be one of the most complete of its kind yet constructed in connection with any electric tram system. It will be built under the personal superintendence of Mr. J. Clifton Robinson, C.E., engineer of the company, on the site of the present depôt in Shelbourne-road, and as it will take in the existing stables and the adjoining plot of land, the structure will be of considerable extent, having a frontage of 200ft. by a depth of 300ft. The works are to be completed within the next three months, the contract including the whole of the generators, steam-engines, boilers, machine-shops, electrical works, and offices of the company. There will be accommodation for 40 new cars, which are being built for the electric equipment of the line by Messrs George F. Milnes and Co., of Birkenhead. During the present month it is expected that the double line of rails will be completed through the Pembroke township, and there is every probability that within the next three months the new line will be open to Blackrock Poles have been erected on both sides of Northumberland-road, next Ball's Bridge, these being 33ft. high and 125ft. apart. They are sunk 6ft. in the earth, which is concreted on the surface.

Ipswich.—A meeting of the Town Council was held on Wednesday, when the Electric Lighting Committee stated that, acting upon the resolution of the Council of April 25, 1894, that they should take steps to obtain an electric lighting order, they requested Prof. Kennedy to report generally upon the mode of lighting which would be most suitable for Ipswich, the best site for the central station, and the cost of the necessary works and plant. Prof. Kennedy visited Ipswich on several occasions, and, having made himself thoroughly acquainted with the district, presented his report. Since the appointment of that committee the advan-

Digitized by Google

tage and greatly increased illuminating power which could be obtained at a trifling outlay by adopting the incandescent system of lighting with gas, had become more generally known and appreciated, and it appeared probable that recent scientific discoveries might lead to the adoption of other methods of increasing the illuminating power and purity of coal gas without increasing its cost. Under these circumstances, and having regard to the large expenditure involved in carrying out electric lighting in the borough, the committee recommended that no further steps be taken to obtain a provisional order for the present. The committee arranged with Prof. Kennedy that his fee for report, etc., should be 100 guineas, and they recommended that a cheque should be drawn for that amount. On the motion of Mr. Pratt, the discussion on this report was postponed till the next meeting.

The Loan to the St. Pancras Vestry.—A long report was presented on Tuesday to the London County Council by the Finance Committee on the subject of the limitation of time in connection with loans for electric lighting purposes, the subject coming up in reference to the application of the St. Pancras Vestry for a loan of £14,600. Finally they recommended: "(*a*) That, subject to the Council hereafter giving its written consent under seal to the borrowing, and subject to all necessary consents and evidence being furnished to the satisfaction of the solicitor of the Council, the application of the Vestry of St. Pancras for a further loan of £14,600 towards defraying the cost of an electric light installation in that parish be granted to the extent of £14,300, on condition that the loan be taken up at once, interest being charged thereon at the rate of £3. 5s. per cent. per annum, calculated quarterly, and with the principal being repaid by such equal half-yearly payments of principal and interest combined as will repay the amount borrowed within a period of 42 years; that it be referred to the solicitor to take the necessary measures for completing the loan, and that the amount be advanced out of the consolidated loans fund. (*b*) That it be notified to the Vestry of St. Pancras that as they have elected to spread the whole of the initial cost of the electric light installation over 42 years, the Council will decline to sanction the raising of any loan to replace any of the works, plant, and machinery during the currency of the loan, and will expect the Vestry to provide for all such renewals as may be required during that period out of a sinking fund to be established, or out of maintenance account."

Rottingdean.—A meeting of the Parish Council has been held at which a letter was submitted from Messrs. New and Mayne, electric lighting engineers, of Westminster, offering to supply and erect not less than five street lights in the main streets not more than 60ft. from their mains and to supply the current to the lamps and maintain them for £4. 4s. per lamp per annum, the lamps to be lighted for 2,000 hours during the year, the lights to be of 16 c.p. It was eventually resolved, on the motion of Mr. Welfare, seconded by Mr. Savage, that a parish meeting be called to consider the advisability of adopting the Lighting and Watching Act for the parish with a view to dealing with this offer. The Council also had under consideration a letter which had been received from Mr Magnus Volk, acting secretary to the Brighton and Rottingdean Seashore Electric Railway Company, asking the consent of the Council to the company connecting the approach to the company's jetty with the Gap, which work it was stated, would not encroach on the Gap so as to offer any obstruction, while it was represented that the concealment of the old drain and the repairing of the pathway at that end would be an improvement to the appearance of the Gap. It was added that it was the desire of the company to open the jetty before Whitsuntide, and that the Marquis of Abergavenny's consent, so far as the sea beach was concerned had been obtained. Ultimately, after considerable discussion, Mr. Savage proposed that temporary leave be granted to the company to construct a sloping gangway to the beach and to effect a landing at the bottom of the Gap in such a manner that it should not interfere with the traffic. This motion was carried.

Torquay.—The Town Council on Tuesday received a report from the Electric Lighting Committee. The committee had ascertained that many of the large ratepayers in the area recommended for lighting with electricity by Mr. Trentham would be willing to take the light for private purposes if it were introduced by the Corporation, but, on the whole, they considered it would be preferable to adopt the scheme first propounded by Mr. Trentham and recommended by the committee on August 31, 1893. The committee had also considered whether it would be advantageous to deal with the matter in connection with the proposed refuse destructor, but they were of opinion that it would be better, for the present, to treat each as a separate question. The committee therefore again directed attention to Mr. Trentham's report, from which it would be observed that the estimated outlay, cost of maintenance, and probable income to be derived in the first instance, not including that obtained from meters, motors, etc., were: capital cost £17,403, annual cost £3,300. The estimated revenue per annum was at 6d. per unit £3,320, at 7d. per unit £3,820, at 8d. £4,320. The committee recommended that the necessary steps be taken, and application be made to the Local Government Board for sanction to borrow £18,000 for the purpose of providing a central station with plant and machinery under the bath saloons, and distributing mains for the compulsory area referred to in Section 17 of the Torquay electric lighting order of 1891. The report stated that Mr. R. Crocker voted against the recommendation. Alderman Kerswell moved the adoption of the report, which was seconded by Alderman Harrison. Mr. Butland said the Council must certainly keep the electric light powers in their own hands, but the present was not an opportune time for carrying out the work. Some thousands of pounds would shortly be wanted for completing works already in hand, and their debt was already heavy. He moved that the subject be referred back to the committee, and that application be made to the Board of Trade for an extension of the time for which the provisional powers were granted. Mr. R. Crocker seconded. Mr. Butland's amendment was carried.

Leeds.—The erection of the new General Post Office is now approaching completion. It occupies a central site. Amongst the fresh features that will manifest themselves when the opening takes place, probably none will be of greater interest than that which provides for the electrical equipment of the new building. This scheme, which has been designed by Mr. W. H. Preece, and carried out under the general superintendence of Mr. J. C. Chambers, superintending engineer, provides not only for lighting the whole of the building by the electric light, but also for putting electrical power to uses which it has not hitherto been applied to in any other post office. The current will be generated upon the premises, the boiler-house and dynamo-room being situated in the basement at the south-west corner of the building. The contract for the boilers has been placed with Messrs. Babcock and Wilcox. Three boilers of the water-tube type will be laid down, each capable of evaporating 3,000lb. of water per hour into steam at 125lb. pressure per square inch. The steam dynamos, three in number, are being supplied by Messrs J. H. Holmes and Co., of Newcastle, the combination being Willans engines, 60 h.p. indicated, driving Holmes dynamos direct. The dynamos will each supply 340 amperes of current at 108 volts pressure. The internal wiring will be carried out by Messrs. Lund Bros. and Co., of London. There are to be in all 36 arc and 563 incandescent lamps, chiefly of 16 c p. The arc lamps will be used in the large letter and parcel sorting-rooms, in the main telegraph-room, and also in the public office. The main switchboard for electric lighting in the dynamo-room, which has been specially designed, will be very handsome, and embody all the latest improvements in switches and measuring instruments. All these contracts (for which Mr. R. Gill is the resident clerk of works) are well in hand. The boilers are in course of erection, and a large part of the building has already been fitted up for the electric light. At the four corners of the main building, hoists connecting the different floors are being erected. By means of motors electrical energy will be used for working these lifts. In the present building telegraph messages are sent from one part of the building to another by means of hand pumps. This method will be abandoned in the new building, where containers will be erected, in which air under pressure, and in partial vacuum, will be stored. By this means telegrams will be driven in small carriers along tubes to the different telegraph departments within the building, and probably to and from one or two of the more important outside offices. The vacuum and pressure pumps that feed the containers will be worked by an electric motor.

Rochdale.—The borough surveyor's report as to schemes for lighting the Town Hall and other public buildings by electricity has been published and circulated among the members of the Town Council this week. Mr. Platt prepared the report for the information of the Electric Lighting Sub-Committee of the General Purposes Committee, and it was after carefully considering it that the sub-committee decided to recommend "the postponement of any electric lighting of the public buildings of Rochdale until the Corporation determines upon a general scheme for lighting a section of the town." This recommendation was subsequently approved by the committee, and on the 4th ult. the Town Council confirmed the minutes of the committee. Mr. Platt states that the more the subject is considered the less advisable it appears to hastily adopt any plan which will not, when required, adapt itself to conversion to a central electric lighting station. At the sanitary works the steam power available for the purpose of generating electricity is equal to 200 i.h.p., and under present arrangements 100 i.h.p. can be guaranteed continuously, excepting during the usual times of stoppage (Saturday noon to Sunday midnight) without increasing the staff of stokers. Owing to the non-central position of the sanitary works, Mr. Platt considers that this possible site for the generation and distribution of the electric light should not be adopted hastily, especially as the cost of steam production does not form an important portion in regard to the total cost of supplying electricity. Appended to the report are several alternative schemes showing the cost of installing and maintaining the electric light for use in public buildings. In one of these—proposing to make an installation in the basement of the Town Hall, to supply the Town Hall, the free library, and the technical school only—the estimated total cost appears as £5,202, and the estimated annual cost as £947. If, however, a central station for supplying the public with light were provided, the annual cost of electric lighting in all the public buildings would be reduced to £877, and that of lighting the Town Hall, free library, and technical school only would be £757. For the purpose of comparison, it is mentioned that the cost of lighting the public buildings by gas last year was £406. 10s. 4d., of which £354. 3s. 11d. was the share of the Town Hall, free library, and technical school. To this part of the report Mr. Platt appends a note stating that the figures given do not include anything for interest and sinking fund, and that the greater safety, cleanliness, convenience, and healthiness of the electric light ought to be taken into account in any comparison of the two illuminants. In relation to the estimate of total cost of electric lighting works, the report states that if the repayment of capital borrowed for this purpose be limited to a period of 10 years, the annual cost of the suggested installation at the Town Hall will be increased by about £170. Since the report was presented to the committee, it has been ascertained that the Local Government Board would limit the period of repayment to 10 years.

PROVISIONAL PATENTS, 1895.

APRIL 29.

8398. **Improvements in the supporting and carrying of electric cables for conveying electricity over large areas, and to varying positions, whether for plough-driving, telegraphic, lighting, or other purposes.** Arthur Samuel Francis Robinson, 46, Lincoln's-inn-fields, London.

8421. **A new or improved automatic switch for electric welding and other purposes.** Reginald Falshaw, 1, Broad-street-buildings, Liverpool street, London.

8453. **Improvements in electrical switches and means of actuating same.** James Brockie, 28, Southampton-buildings, Chancery-lane, London.

APRIL 30.

8492. **Improvements in and relating to ships' telegraphs.** John William Ray and Robert Coleman Saxby, 26, Castle-street, Liverpool.

8493. **Improvements in and relating to ships' automatic reply telegraphs.** John William Ray and Robert Coleman Saxby, 26, Castle-street, Liverpool.

8505. **Improvements in the mode of and means for electrically transmitting articulate speech.** Charles Arthur Allison, 52, Chancery-lane, London. (John Absterdam, United States.)

8507. **Improvements in disconnection fuse-boxes.** Joseph Alexander Jeckell, Borough Electrical Engineer's Office, South Shields.

8564. **Improvements in electric alarms.** Alexandre Duceux, 55, Chancery-lane, London.

8573. **Improvements in electric cables and in their manufacture.** Willoughby Statham Smith and William Puddicombe Granville, 24, Southampton buildings, Chancery-lane, London.

8583. **Electro-automatic "block system" apparatus.** Alfred Berry and Joseph Lipkowski, 1, Queen Victoria-street, London. (Date applied for under Patents, etc, Act, 1883, Section 103, October 30, 1894, being date of application in France.)

8590. **Improvements in magnetic ore separators.** John Wendell Carter, Norfolk House, Norfolk-street, London. (Complete specification.)

MAY 1.

8603. **Improvements in terminals for electrical conductors.** Henry Reason and George William Goldring, 111, Gloucester-road, Brighton.

8637. **Improvements in secondary batteries.** Edward Clark, 84, West Ferry-road, Millwall, London.

8654. **A rectifier for alternating electrical currents** Frank Edward Beeton, 40, Chancery-lane, London.

8664. **Improvements in electric arc lamps.** Rookes Evelyn Bell Crompton and Edmund Arthur Norman Pochin, 55, Chancery-lane, London.

MAY 2.

8671. **Improvements in operating and controlling electrical and other cranes and hoisting machinery.** John George Fiegehen and Edward George Fiegehen, Stafford Lodge, Ampthill-road, Bedford.

8696. **Improvements in electric distribution and apparatus in connection therewith.** Arthur Wright and Robert Cornelius Quin, 26, Park-crescent, Brighton.

8726. **Improvements in electric motors, generators, and current-converting apparatus.** Silvanus Phillips Thompson, the Technical College, Finsbury, London.

8727. **Improvements in switches for varying electrical resistance.** Siemens Bros and Co., Limited, and Eduard Friedrich Hermann Heinrich Lauckert, 28, Southampton-buildings, Chancery-lane, London.

8729. **An improvement in secondary voltaic batteries.** Ludwig Epstein, 28, Southampton-buildings, Chancery-lane, London.

8731. **Improvements in electric arc lamps.** James Brockie, 28, Southampton-buildings, Chancery-lane, London.

8740. **Improvements in secondary batteries.** Mark Bailey and John Warner, 21, Finsbury-pavement, London.

MAY 3.

8764. **Improvements in distribution of electricity.** Arthur Wright, 26, Park-crescent, Brighton.

8801. **Improvements in telephones.** George Lee Anders and Edward Priddle, 33, Peak-hill-gardens, Sydenham, London.

8810. **Method of, and apparatus for, directly indicating the value of electrical resistances.** Siemens Bros. and Co, Limited, 28, Southampton-buildings, Chancery-lane, London. (Messrs. Siemens and Halske, Germany.)

8834. **An improved system of electric traction.** Otto Lindner and Charles Van Sweevelt, 70, Chancery-lane, London. (Complete specification.)

MAY 4.

8876. **Improvements in or connected with electric batteries.** Charles Percy Shrewsbury, Frank Laurence Marshall, John Cooper, and John Laskey Dobell, 57, Chancery-lane, London.

8904. **Improvements in primary and secondary battery plates.** Carl Ludwig Rudolph Ernest Menges, 45, Southampton-buildings, Chancery-lane, London.

8905. **Improvements in primary and secondary galvanic batteries.** Carl Ludwig Rudolph Ernest Menges, 45, Southampton-buildings, Chancery-lane, London.

8914. **Improvements in the preparation of chloride of lead for use in electrical storage batteries and for other purposes.** Alfred Roland Davis, 4, South-street, Finsbury, London.

SPECIFICATIONS PUBLISHED.

1894.

5391. **Electric railways and tramways.** Aldred.

7530. **Electrical glow lamps.** Edison and Swan United Electric Light Company, Limited, and Moffat.

7726. **Storage batteries, steam generators, etc.** Rollason and others.

9285. **Electrodes.** Kellner.

10978. **Electric measuring instruments.** Goolden and Evershed.

11059. **Varying the phases in polyphase electric currents, etc.** Rowland.

11136 **Regulating electric distribution systems.** Wood.

11323. **Telegraph lines and cables.** Muirhead and Fraser.

11587. **Electrolytic decomposition of solutions, etc.** Hulin.

12183. **Electric railways.** Parker.

12283. **Electric railways.** Langén.

12400. **Arc lamp regulators.** Suisse and Henniquin.

15455. **Telegraphic transmitters.** Howe.

20596. **Electric accumulators.** Hammacher.

22965. **Electrically heating and welding metals.** Th ompson. (Coffin.)

23858. **Measuring electric currents.** Nalder and others.

24745. **Electric light ceiling fittings.** Curley.

1895.

358. **Secondary battery electrodes.** Wershoven.

1546. **Electric switch.** Wright and Piper.

3779. **Arc lamps.** Albrecht.

5099. **Electric gas lighter.** Kass.

NOTES.

Book Received.—"Telegraphy," by W. H. Preece, C.B., F.R.S., and J. Sivewright, M.A., K.C.M.G. Eleventh edition. Published by Messrs. Longmans and Co. Price 5s.

Lectures to Students.—On Tuesday, May 28, Mr. James Swinburne will commence his usual course of lectures on "The Construction of Dynamos, Alternators, and Transformers" to the students of the Electrical Standardising, Testing, and Training Institution, at Faraday House, Charing Cross-road, W.C.

The Telephone Service in the City.—The circular issued by the Commission of Sewers, asking for an expression of opinion by telephone users in the City as to the merits and demerits of the existing service, has been answered by considerably over a thousand persons, the great majority of whom appear to be in favour of a more efficient service. Although the circulars were only issued on Wednesday, 500 replies to it were received early on the following morning.

Insulator with Resin Base.—M. Gentzch prepares an electric insulating material in the following manner. He heats resinous substances such as ozokerite, amber, and asphalte in a retort, at a temperature of 400deg. C., until the condensable or gaseous volatile products are liberated. The result is a black residue having when cold the consistency of wax or dry resin, and capable of being used either alone or in conjunction with guttapercha, other resins, mineral powders, or with sulphur, as a cable insulator. The material, it is said, has sufficient plasticity to lend itself readily to the turnings and twistings to which the wires of cables are generally subjected. The proportions of the raw substances used should be preferably ozokerite 50 parts, yellow amber 45 parts, and asphalte five parts.

The Telephone on Railways.—At a recent meeting of the Society for the Promotion of Local and Street Railways in Vienna, Herr Anton Watzka, of the Austro-Hungarian State Railways, gave a paper on the use of movable field-telephones in railway service, illustrating his remarks by the aid of a number of specimen instruments lent for the occasion by the Wiener Mikrophon und Telephonfabrik J. Berliner. Especially useful, he said, were the apparatus he was discussing in case of accidents and breakdowns, where it was necessary to have an easily portable and quickly usable means of transmitting and receiving information or instructions. Specific cases of their utility on several local lines were mentioned; and the speaker, in conclusion, maintained that we had, in the field-telephone, a simple, reliable, and cheap method of providing for any emergency in which it was essential that communication should be rapidly established, and where ordinary telephone wires were not available.

Electrometallurgy.—At the recent meeting of learned societies—Congrès des Sociétés Savantes—in Paris, M. H. Moissan remarked, in the course of a dissertation on electrometallurgy, that he was convinced that the treatment of metals by means of the heat of the electric arc would develop more and more largely, and that thus the forcing upon the ore of the impurities of coal would be obviated. He observed, too, that during his extended electrometallurgical researches he had had occasion to deal with currents of very diverse intensities. He commenced, he said, with the very modest engine at the Ecole de Pharmacie de Paris—one of 4 h.p. Then, when his appetite was whetted for this class of work, he accepted the hospitality proffered him by Colonel Laussedat, of the Conservatoire des Arts et Métiers, who placed at his disposal a 45-h.p. machine. Finally, the director of the Société Edison, M. Meyer, allowed him free access to the fine electric lighting station in the Avenue Trudaine, where, with his collaborateur, M. Lebeau, he conducted experiments with engines of from 100 h.p. to 300 h.p.

A Curious Electrical Discharge.—Mr. Gus Schade, of Anaheim, Cal., writes as follows to the *Scientific American*: "I am making asphalte pipe. The process is as follows: Crude asphaltum and gravel, equal parts by measure, are each heated in separate kettles to 400deg. F., then both are mixed together and filled into sheet-iron moulds. The space between the moulds is maintained by a cast-iron ring on the bottom and the moulds are held to that ring by inside and outside wrought-iron rings. After the moulds are cooled off, which takes time, according to the size of the pipe, from two to eight hours, they spring off from the pipe after the wrought-iron rings have been removed and the moulds tapped with a hammer. Just at the moment the moulds spring off there can at times be seen large sparks between the sheet iron and the pipe. By having my hands on the pipe and the moulds I received sometimes such heavy shocks as to draw my arms together. Men working for me have experienced the same. The object of this letter is to find out if you or any of your readers can explain how this electricity—for such is what I judge it to be—accumulated there, and why it discharges just at the moment the moulds are taken off. The editor thinks the description suggests that a condenser is formed by the combination, which is discharged on opening the mould. Whence the charge is derived is not clear."

The British Association.—The programme of the Ipswich meeting, which will commence on Wednesday, September 11, has been issued. The president will be Captain Sir Douglas Galton, F.R.S., with Prof. Hicks, F.R.S., president of the Mathematical and Physical Section; Prof. R. Meldola, F.R.S., president of the Chemical Section; W. Whitaker, F.R.S., president of the Geology Section; Prof. W. A. Herdman, president of the Zoology Section; H. J. Mackinder, M.A., president of the Geography Section; L. E. Price, president of the Economic Science and Statistics Section; Prof. L. T. Vernon Harcourt, president of the Mechanical Science Section; Prof. W. M. Flinders Petrie, president of the Anthropology Section; and W. T. Thistleton-Dyer, president of the Botany Section. We notice that Prof. Silvanus Thompson, F.R.S., is to deliver one of the evening lectures on the subject of magnetism in rotation. This lecture will be delivered on Friday evening, September 13. There is a suggestion which we would offer to the Physical Section—or rather we would make for the third or thirtieth time—and that is that they should emulate in some measure the business method of the Mechanical Section, and so to assist in a better reporting of the various papers, by having the abstracts in the hands of the secretaries previous to the reading of the papers. It is almost impossible for a scientific expert to report the gist of a paper which is given in abstract and in pantomime, with a promise of future extension, and totally impossible for the ordinary reporter so to do. If the British Association, or, rather, one or two particular sections of it, are to recover from the dreary monotony of empty benches, more attention will have to be given to the quality of the papers sent in and to the possibility of their being adequately reported for the general reader.

Electricity and Prestidigitation.—The powerful aid which modern magicians are able to derive from the

Digitized by Google

subtle electric current is common knowledge, and little wonder is there consequently that from time to time these wizards startle the wonder-loving world with new and striking developments in their "black art." One of the latest efforts in this direction is that of M. Trouvé, who, through the intermediary of the prestidigitateur Roskoff, utilises the telephone in the production of that interesting attribute known as *double vue*, or second sight. The medium, whose task, as we know, is to describe for the benefit of the audience unseen objects selected by them, receives, by the Trouvé method, the necessary information by means of two very sensitive auricular telephones. These instruments—the size of a two-franc piece and from 8 to 10 millimetres thick—consist of a small metallic box, in which there is a tiny electromagnet, while the lid of the receptacle represents the diaphragm. The conductors form, in the first place, a flexible semicircle, which keeps the telephones in proximity to the ear, and they are then continued down the body, hidden in the clothing, and out by the soles of the shoes to the carpet, under which the connections are secretly disposed. The receivers and the wire semicircle are concealed by a wig which the medium should wear, together with a costume in keeping with this hirsute adornment. The public will never suspect the existence of electrical apparatus, but as an additional precaution connections should be placed at various points in the room, and the subject, blindfolded and with his back to the audience, installed successively at each of them, the telephones being connected with a battery and a microphone fixed "behind the scenes." The articles which he has to describe are then so placed on a table that a confederate at the hidden transmitter may easily see them by peering through a small orifice, and thus communicate to the medium in a low voice the necessary particulars, which he repeats for the edification and to the no little astonishment of his auditors.

The Mersey Railway.—There is quite a plethora of important electrical news concerning Liverpool this week. First, there is the report, mentioned in another column, of Sir Frederick Bramwell relative to the acquisition by the Corporation of the plant and goodwill of the Electric Supply Company, for the sum of £400,000; and then there is the Bill of the Mersey Railway, the "underground" of Liverpool, seeking to have that brilliant but not very fortunate steam undertaking converted into an electrical line, which came before a committee of the House of Lords on Monday. Mr. Monroe, for the promoters of the Bill, said that from the experience of the working by electricity of the South London Railway, with a heavy gradient, there was good reason to believe that a great economy would be effected in the cost of working the railway were electric traction adopted, while the public would have a more frequent train service. Mr. A. Sarle, general manager of the London, Brighton, and South Coast Railway, and for the last four years official receiver of the Mersey Railway Company, stated that it was estimated that there would be a saving of about £14,000 a year in cost of ventilation and in working the railway by the new method. The cost of the change, supposing they required new rolling-stock, would be, he said, £80,000, but it was believed that the motors proposed to be used could be applied to the existing rolling-stock, and that would save about £25,000 of the first estimate. Sir Douglas Fox spoke strongly in favour of the use of electrical traction in a case of this kind, and was quite certain from experience on the Liverpool Overhead Railway, and from experiments first made on the Baltimore and Ohio Railway, that the plan was perfectly feasible and economical. Mr. A. Siemens estimated that the cost of working would be one-third less, and he said that there was nothing to prevent the construction of electro-locomotives sufficiently powerful for goods trains. With an insulated return, he remarked, there would be no interference with railway signals or electrical wires. The committee, in the event, said they would find the preamble proved subject to words being inserted which would make it quite clear that the spirit of the agreement of May 14, 1894, as to through traffic, was agreed to.

Electricity Direct from Coal.—The endeavours of scientists and inventors to convert directly the potential energy of coal into electrical energy have received a fresh incentive from the interesting experiments of Dr. Borchers. So alluring are the rewards that follow the solution of this problem that men known for their conservative attitude in similar questions have hailed with extravagant expressions of delight the seeming results of the German electrometallurgist. It is true the latter deserves high credit for testing his ingenious idea, yet from his own account of the facts brought out in his experiments it is not sure that his theories are established. Such failure, it is only just to note, could not have been foreseen from the standpoint of our present knowledge of electro-chemistry. In the extensive discussion of Dr. Borchers's work, which appeared in various technical and scientific journals, one point has been altogether ignored, and this point is of such essential importance in the problem of the conversion of the potential energy of coal into electric energy that it deserves to be fully elucidated. This point is the relation of chemical to electrical energy. Dr. Borchers erroneously supposed that it would be possible to obtain an amount of electrical energy from the reaction $2CO + O_2 = 2CO_2$ that would be equal to the heat of formation of as much of the quantity of the reacting substances as take part in the transformation. Since Helmholtz has shown that such a view does conflict with facts, it is not legitimate to assume its correctness, still less to base upon it efficient calculations, as has been done by Drs. Borchers and Ostwald. Mr. A. H. Bucheru, in a paper read on this subject in America, concludes that the maximum E.M.F. we can expect to gain from the combination of carbon monoxide with oxygen is 1·406 volts. Dr. Borchers claims to have succeeded in obtaining 0·5 volt, but not in a commercial form of apparatus. For reasons which were well stated by the latter, it is more expedient and apparently easier to utilise the combination of carbon monoxide with oxygen for the generation of electric energy, instead of that of carbon with oxygen. The work done by Dr. Borchers, though not crowned with success as yet, is, nevertheless, of high value on account of its instructiveness. It indicates in its general features the path that has to be followed for accomplishing a most important industrial task, the fulfilment of which we hope this century will yet witness.

Communication with Lightships.—The third report of the Royal Commission on the question of electrical communication to lighthouses and light-vessels has just been issued. The Commissioners since they issued their second report have considered some further inventions for establishing electrical communication with light-vessels, but still consider that the "Sunk" is the best system of continuous connection which has yet been brought to their notice. In this system, which has been maintained on four vessels since 1886, the ship is moored by two or more chain cables attached to mushroom anchors and shackled to the lower part of a patent swivel, to the upper end of which are shackled the vessel's two bridle chains. The electric cable on its way

Digitized by Google

from the shore passes through the centre of the swivel, and entering the bow of the ship between the knightheads, is coiled on a drum fitted to a revolving frame placed between decks, by means of which turns made in the cable when the lightship swings round with the change of tide can be taken out. This system permits of the free use of the telephone, which in the opinion of the commissioners is an important advantage. After giving an account of the faults which have occurred in the various cables used for these purposes, the report gives the following list of occasions on which the connections have been of valuable services to the shipping community: Kentish Knock light-vessel (connected March 14, 1894), on six occasions; Goodwin (North Sand Head) light-vessel (connected March 24. 1894), on nine occasions; Hasborough light-vessel (connected October 2, 1894), on two occasions; Shipwash light-vessel (connected November 17, 1894), on one occasion; Gunfleet pile lighthouse (connected October 2, 1893), on 19 occasions. No use for life-saving purposes have been made of the cables to the Lundy lighthouse (connected July 18, 1893) and the Tuskar lighthouse (connected September 10, 1894). As regards shore lighthouses, use had been made of the electrical communication for such purposes with the Start Point lighthouse on four occasions, Needles lighthouse on three occasions, South Stack lighthouse on two occasions, Nash lighthouses on two occasions, Bull Point lighthouse on one occasion, Point of Ayre lighthouse on one occasion, Douglas Head lighthouse on one occasion, Hook Point lighthouse on one occasion. The report concludes with a list of further communication needed, and also gives all the details as to the various urgent calls for assistance which have been forwarded to the mainland or to points whence help could be rendered. We trust that the recommendations as to extensions will be speedily carried into effect.

"A Little Knowledge is a Dangerous Thing" (Pope).—Our contemporary *London* has, in its issue of May 9, aired its opinions as to consulting electrical engineers. Unfortunately, these opinions must be largely discounted, in that they are evidently written with a bias. The immediate object of the article is a description of the central station at Islington, and it goes out of its way to run down the consultant. This is what it says: "Islington never employed a consulting engineer. The consulting engineer is very much like a physician: he thoroughly understands theory; but all sensible people call in the surgeon—the practical man—when practical work has to be done. There is hardly a consulting engineer in existence who has had experience of the practical day-to-day running of an electric lighting station for six months together. Consulting engineers have profited largely from the general ignorance prevailing as to electric lighting. A municipality, anxious to keep pace with modern developments, decides to establish the electric light. The consulting engineer is at once called in; he is usually supported fully and fee'd in like manner. What happens? When the undertaking is complete a superintending engineer must then be placed in charge, and in nine cases out of ten before he, as a practical man, can take up the new duties he is bound to rearrange the whole system, often at considerable cost, otherwise failure becomes inevitable. The fact is the superintending engineer ought to be appointed the day the works are put in hand, instead of on the day of their completion, so that he can exercise a personal supervision over the construction of the undertaking he will eventually have to control. Islington has proved that the consulting engineer is not necessary. They first of all made their own enquiries, and then before beginning to build appointed a superintending engineer of first-class experience." Now, a paragraph of more absurd and ignorant twaddle never emanated from the pen of a responsible journalist. We contend that the consulting engineer is a necessity. It is impossible to point a moral by reference to electrical work, because someone endowed with the folly of ignorance would be sure to attribute personality. We would, however, ask our contemporary if it would argue that the man who drives and manages the locomotive must of necessity be the best man to design one. As a matter of fact, the driver of an engine may be totally ignorant of the first principles of design. Nor does it hold good that the best designer of a locomotive is the best driver. Every man to his place, and in his place. The bricklayer is not an architect, and the architect is not a bricklayer. The best managers of central stations are not necessarily the best designers; indeed, we should expect them to turn out to be about the worst. There is no disparagement intended; but reading between the lines of this paragraph from *London*, it is easily seen that the desire is to encourage narrowmindedness and mediocrity.

Resonance in Alternating-Current Lines.—Messrs. Edwin J. Houston and A. E. Kennelly have read a paper on this subject before the American Institute of Electrical Engineers, of which the following is an abstract. In a paper, by one of the authors, on the subject of "Impedance," read before the institute on April 18, 1893, the drop of pressure in conductors carrying alternating currents, and assumed to possess no capacity, was considered. In the present paper, the authors consider the conditions of current and pressure in an alternating-current circuit, possessing electrostatic capacity as well as inductance, resistance, and leakage. The authors present formulæ expressing the variation of electric current and pressure in an alternating-current circuit under the most general conditions, and in its simplest form. They give calculations for the pressure and current in any alternating-current circuit by a graphical method, presenting a chart which gives by inspection the polar co-ordinates of a vector point, representing the hyperbolic cosine or sine of a given vector whose rectangular co-ordinates are known. They also investigate the effects of static capacity and of capacity and inductance on the delivery of energy at the distant end of an alternating-current circuit. The conclusions arrived at by the authors are as follows: (1) The combined effect of capacity and inductance is to produce a tendency to resonance. (2) The tendency to resonance is favoured by high frequency, high insulation, high inductance, high capacity, and high conductance. (3) When the line is free at the distant end, the resonant effects are more pronounced at that end than at the generator. (4) The determining factor for the production of resonance is the angle of the vector geometric mean conductor impedance dielectric admittance, and rapidly increases with the same. (5) The complete wave-length in a resonant line is 2π times the length, in which the reactances of the inductance and the capacity are equal, the maximum difference of pressure or current strength being exhibited in one-quarter of this wave-length. (6) When resonance occurs, the current and pressure in the circuit are not in phase except at their maximum and minimum values—*i.e.*, at the crests and troughs of the waves. (7) In resonant circuits, the lag of the pressure and current is 90deg. between any successive pair of maximum and minimum values. (8) In ordinary lines, worked sinusoidally at ordinary frequencies, resonant effects are practically negligible. (9) Prominent upper harmonics in the E.M.F. of the generator may sometimes give rise to appreciable resonant effects, although the resonance to the fundamental frequency may be inappreci-

Digitized by Google

able. (10) A certain amount of capacity tends to increase the plant efficiency of the generator, and is, therefore, economical, but marked resonance in a line not only ceases to be economical, but is actually wasteful. (11) Although, on a large scale, less energy can be delivered at the distant end of a powerfully resonant line than on a non-resonant line, yet a greater current strength can in some cases be delivered over a powerfully resonant line.

Telephones.—The Select Committee of the House of Commons on the Telephone Service heard further evidence on Tuesday, Mr. Arnold Morley (the Postmaster-General) presiding. Major-General Webber, C.B., formerly divisional engineer for postal telegraphs, who had charge of the telegraph service in the Egyptian War, and since his retirement from active service had been managing director of the Bell-Edison United Telephone Company, stated, in answer to Sir C. Cameron, that he was not altogether in favour of Government monopoly. His view of the possible extension of telephony made him think it might get beyond the management of even such a great department as the Post Office. In his opinion the Post Office were right in securing the arteries of the system, and in thinking they could manage better than anyone else that part of the system which was essentially used for commercial purposes; but as regarded what he called the great system of capillaries, which might come into existence in this country in the future, it might be wise to leave that in the hands of private enterprise. There were two forces which had prevented the development of the telephone in this country. One was the natural caution of the Post Office in preventing by every means in their power the extension of the telephone from fear that it would compete with their telegraphs. Another was the inception of the monopoly which, having the possession of the patents, could prevent anybody else using it, and the fact that every sub-company was really the creature of the head company, and therefore the policy of the head company prevented the operations of all the minor sub-companies. In London the engineering arrangements for telephone extension had grown up haphazard to the most lamentable extent. To establish one great centre of exchange was impossible in the City, because there was not space to lay down, radiating from one centre, a sufficient number of tubes to cover the surface which would probably be required. In order to meet that difficulty, he proposed to the late Duke of Marlborough to establish eight telephonic exchanges at different points in the City, with the wires conducted in tubes underground. There was no engineering difficulty in establishing such a system now without the abomination of overhead wires. The plan he contemplated would accommodate 28,000 subscribers in the City alone. Each of these eight exchanges might have 3,000 subscribers, and would be capable of serving subscribers outside for a distance of three-quarters of a mile on the north and half a mile on the south of the river, so that there was the nucleus of a system in London which ought to serve 50,000 subscribers, taking an area outside the City of three-quarters of a mile in every direction. As regarded rural districts, he thought the telephone ought to take precedence of light railways, and he described a scheme by which a call office might be established in every village and hamlet of a county, the call office being connected with the market town, and conversations allowed at 2d. each. In answer to the chairman, the witness stated that the subscribers on each of the eight City exchanges would pay a minimum charge of £8 a year, with an extra toll for a connection with another exchange, or an increased subscription to be connected with all the eight exchanges. He had not formed an estimate of what this inclusive charge would be, but probably it would be about £16 for any place within the City area.

Light and Electrification.—Prof. O. J. Lodge has written an article in the current number of *Science Progress* bearing this title. Anything that Prof. Lodge writes is worthy of the closest attention, and in this article he not only gives certain corroborative evidence of his own experience, but an epitomised history of the experimental evidence in regard to the text of this article. This text is summed up in the first three paragraphs as follows: "If an ordinary gold-leaf electroscope with a freshly-scraped zinc cap or knob is charged with negative electricity, and is then exposed to the unfiltered rays of a source of ultra-violet light, its charges will leak away rapidly. If, further, the electroscope so treated be extremely sensitive, it will be found, not only to lose its negative charge, but to acquire a slight trace of positive charge under the action of light. These are the simple and fundamental facts of what is virtually a new subject or branch of physics, the subject of photo-electric action, the influence of illumination on electrified surfaces." It will be well, perhaps, to indicate the points of the article, but at present we can do no more, but must leave readers themselves to carefully consider what the author says upon the subject. After a summary of historical work, the author enters into the question of experimental details, and points out that a demonstration of the fundamental fact can be made with very simple appliances (though unless they are properly arranged it is easy to fail), coming to the conclusion that the arc light is the most powerfully active source, especially if it is made extra long, still more if a little zinc is placed in the positive crater for volatilisation. Then, the kind of metal exerts considerable influence, and it appears that the order of metals in photo-electric power, when tested by their discharging action for negative electricity, is the same as their order in the voltaic series, and the facts discussed under this heading clearly suggest some chemical or semi-chemical explanation. The author then considers the discharging action of metals for positive electricity, which is very different to the discharge of negative, his own experiments going to show that as metals get dirty the rates of leakage of negative and positive become more comparable, and in the case of cobalt, the positive discharge he has found to be even faster than the negative. One might interpolate here a question as to the fundamental property of electricity, and to ask how equilibrium is continued between the positive and the negative states, in that there cannot be anywhere a greater positive charge than there is a corresponding negative charge somewhere. The question of fatigue, the action of non-metallic substances, and plants are next considered, and there is a promise given that in a future article the author will discuss the final aspect of some facts stated from the point of view of theory; but he again maintains that it is plain in the experiments on metals, at any rate, that a quasi-chemical origin is indicated for the discharging power. As regards the effect of magnetism, the singular observations made by Elster and Geitel are given. They found that if the lines of magnetic force agreed in direction with the lines of electrostatic force they had no appreciable influence on the discharging power of light, but that as soon as the magnetic and the electrostatic lines crossed, the discharging power of light was definitely diminished and interfered with. As we have said, the present article is a summary of the more prominent and interesting facts connected with the subject, and a future article will attempt to collate these facts and consider their bearing with regard to a possible explanation.

CHELTENHAM ELECTRICITY WORKS.

If we mistake not, a previous attempt has been made to supply Cheltenham with the electric light, but not under the auspices of the Corporation. Now, however, that the authorities themselves have taken the work in hand we find every indication of success, as, indeed, will be gleaned from the following brief description of the central station now opened. Of Cheltenham itself we shall say little, for, as an old writer says, it "has been rapidly rising into note as a fashionable place of resort, and is at present eminent for the elegance of its buildings, the extent and variety of its accommodation, and the rank and number of its visitors." Indeed, any praise of ours as regards this fashionable town would be out of place, and we therefore content ourselves with simply saying that both its governing body and its officials are fully alive to the requirements of a modern health resort, and strain every nerve to comply with such requirements.

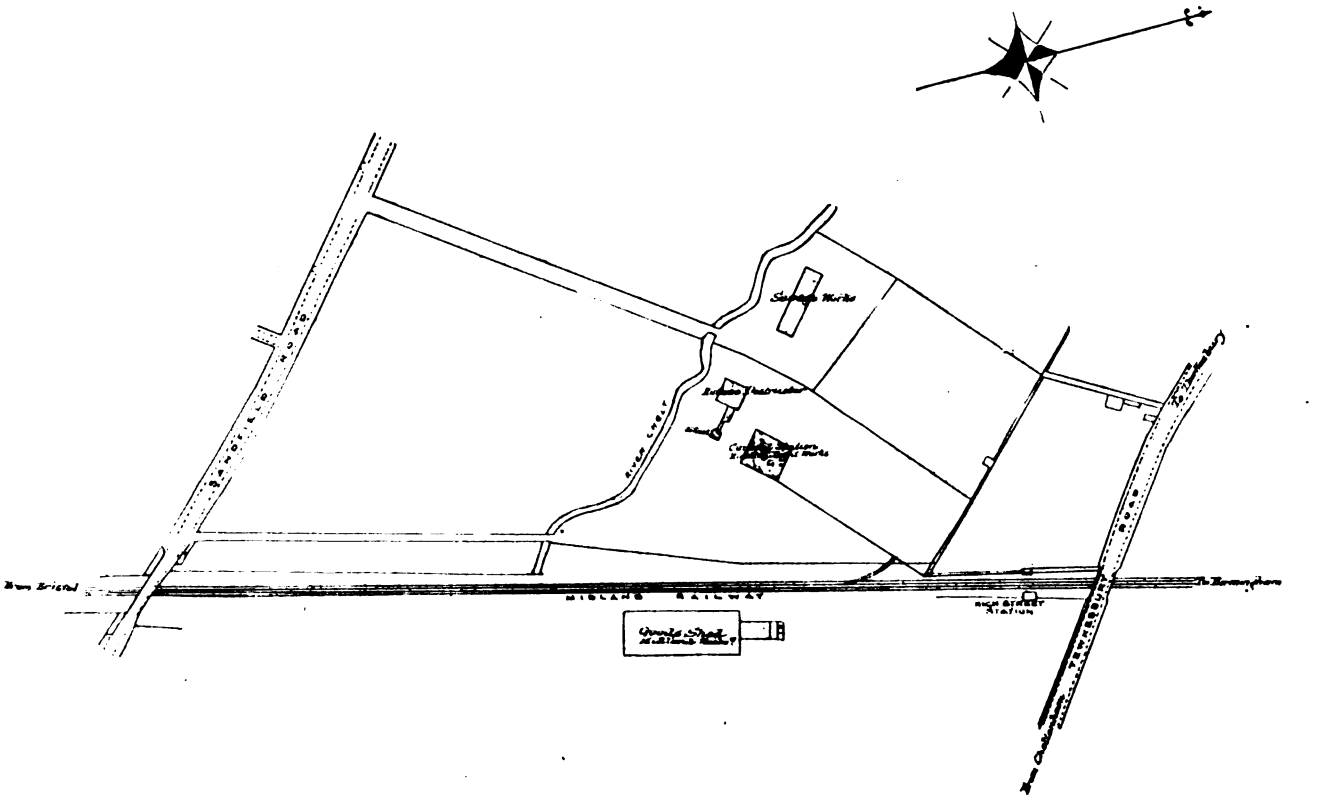

FIG. 1.—Plan of Site of the Electric Lighting Works, Refuse Destructor, and Sewage Works at Cheltenham.

Before describing the generating station and the system of distribution adopted, it may be of interest to briefly recall the history of the movement which has led to the present results. The circumstances under which the order was obtained date back as far as 1889.

Prior to that year the question of electricity supply had not been wholly unthought of in the Council-chamber, but it required the pressure of a threatened invasion of private speculation to stimulate the governing body to a definite policy. The presence of no less than six trading companies in competition before the Board of Trade for the privilege of lighting Cheltenham by the electric light involved three possible alternatives. One of these—that of mere passivity—was clearly out of the question, and there remained the choice of accepting the overtures of a company and consenting to its admission under an arrangement for subsequent purchase, or of excluding private enterprise by taking advantage of the preference given by Government to municipal supply. The Corporation unanimously chose the bolder course. The principle that public services should be in public hands is too late in the day to challenge. The Corporation has throughout adhered to the policy it originally laid down. The provisional order, obtained in the spring session of 1890, specified two years as the limit within which the governing body of the town was free to formulate its scheme, in accordance with the obligation entered into precedent to the acquisition of powers as against a company. Had the Corporation, after temporarily making sure of its position, been disposed to adopt a merely obstructive and dog-in-the-manger attitude, it would not have been suffered to do so beyond the period stated. In March, 1891, when the larger half of the time limit had still to run, the Department in London wrote reminding the Town Council of the responsibilities it had assumed. The Electric Lighting Committee had already paid visits of inspection to various electrical works in London and elsewhere, and on the recommendation of that body the Corporation responded to the pressure of the Board of Trade, and the engineer determined to adopt the ash destructor site (Fig. 1) as the place for the central station, which favoured the high-tension system of distribution. At the same time the borough surveyor was authorised to obtain expert assistance, with the view to a system being agreed upon.

Of the incidents of the long period of enquiry which followed it is unnecessary to say more than that the unanimity which had decided for municipal control gave place to considerable criticism of details and methods, with the result, however, that the scheme put forward by the surveyor, with the sanction of Prof. Ayrton, and subsequently endorsed by Mr. Preece, as *amicus curiæ*, carried conviction to the minds of objectors, and was adopted by a majority of the Council favourable to the policy of Corporation enterprise as originally affirmed. The final determination of the matter was arrived at in August, 1893, when the limit of time specified in the order was on the point of lapsing.

The scheme (based on the system of alternating high-tension current with transformers) involved an initial outlay of £16,000, leave to borrow which was, after the usual official enquiry, obtained from the Local Government Board

Digitized by Google

acting in conjunction with the Board of Trade as the authority having the oversight of such undertakings in their technical and engineering aspect. The machinery of central administration moves slowly, and though the application for borrowing powers had been made in August, 1893, it was not until March last year that the requisite sanction was forthcoming. The official appointment of Mr. M. H. Kilgour as borough electrical engineer, who had been for some time previously assisting the surveyor, followed closely upon the selection of tenders for the various departments of the work—a selection in which special circumstances called for some delay—and, finally, after the first stone of the station had been laid by the mayoress at the beginning of October, a long spell of bad weather seriously retarded operations, both in the laying of the mains and in the completion of the machinery. From one cause and another, the commencement of the work had, in fact, been driven off to too late a period of the year. However, if the realisation of the scheme has proved a more tedious process than was expected, it is satisfactory to know that it has been marked at every stage and in every detail by the thoroughness which is immeasurably to be preferred to haste. For much of our historical information we are indebted to the *Cheltenham Examiner*.

The Electric Lighting Committee is composed of the following gentlemen: Alderman Norman (chairman), the Mayor, Alderman Thoyts, Councillors Dimmer, Lawrence, Parsonage, Wheeler, and H. Waghorne. The chairman (Alderman Norman) has taken an active part throughout in the electric lighting question, and the committee has been admirably advised by the borough engineer and surveyor, Mr. Joseph Hall, who has had full control of the whole of the works. The specifications were drawn up by him, and also some considerable part of the work, notably the laying of the mains, has been done under his supervision by workmen employed by the Corporation. In the electrical problems Mr. Hall has received valuable advice from Mr. M. H. Kilgour, the borough electrical engineer, who has given great attention to the details of the plant.

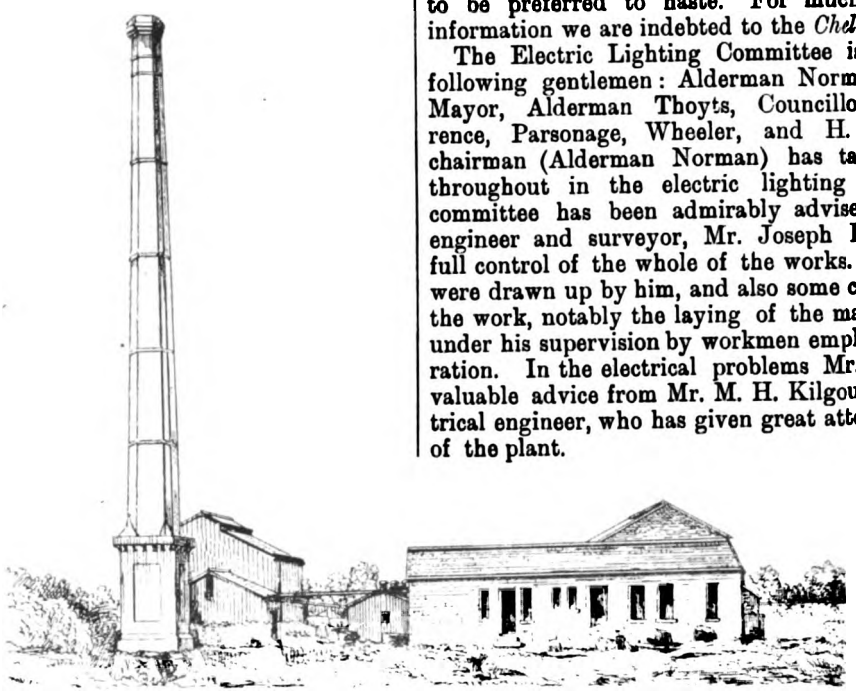

FIG. 2.—View of the Cheltenham Electric Lighting Station, Refuse Destructor, and Sewage Works.

The advantage to a town of having its public wants supplied under the direction of its own engineer is again evident in the case of Cheltenham. By placing the electric lighting station (Fig. 1) near the refuse destructor the following economic advantages accrue: (*a*) the steam generated by the necessary destruction of the house rubbish can be utilised to generate electricity, which can be sold; (*b*) this steam will be enough to run the engines during the lightly-loaded periods of the day, and hence ease the work on the boilers and save the boiler-attendants' wages; (*c*)

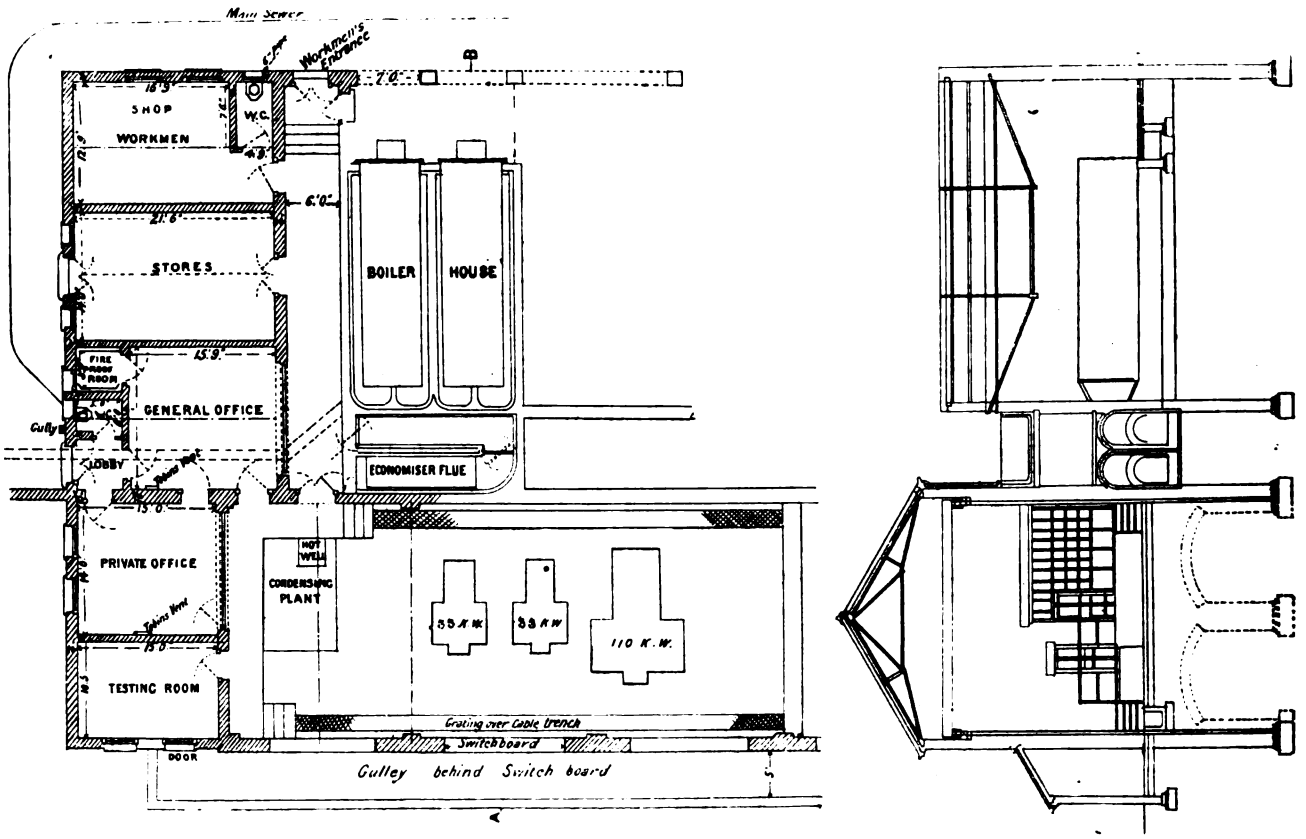

FIG. 3.—Plan and Elevation of the Cheltenham Electric Lighting Works.

one common shaft can be used for the boilers and destructors; (*d*) the two, or in this case three, operations under the engineer's charge can be placed close together, hence saving time in supervision.

Digitized by Google

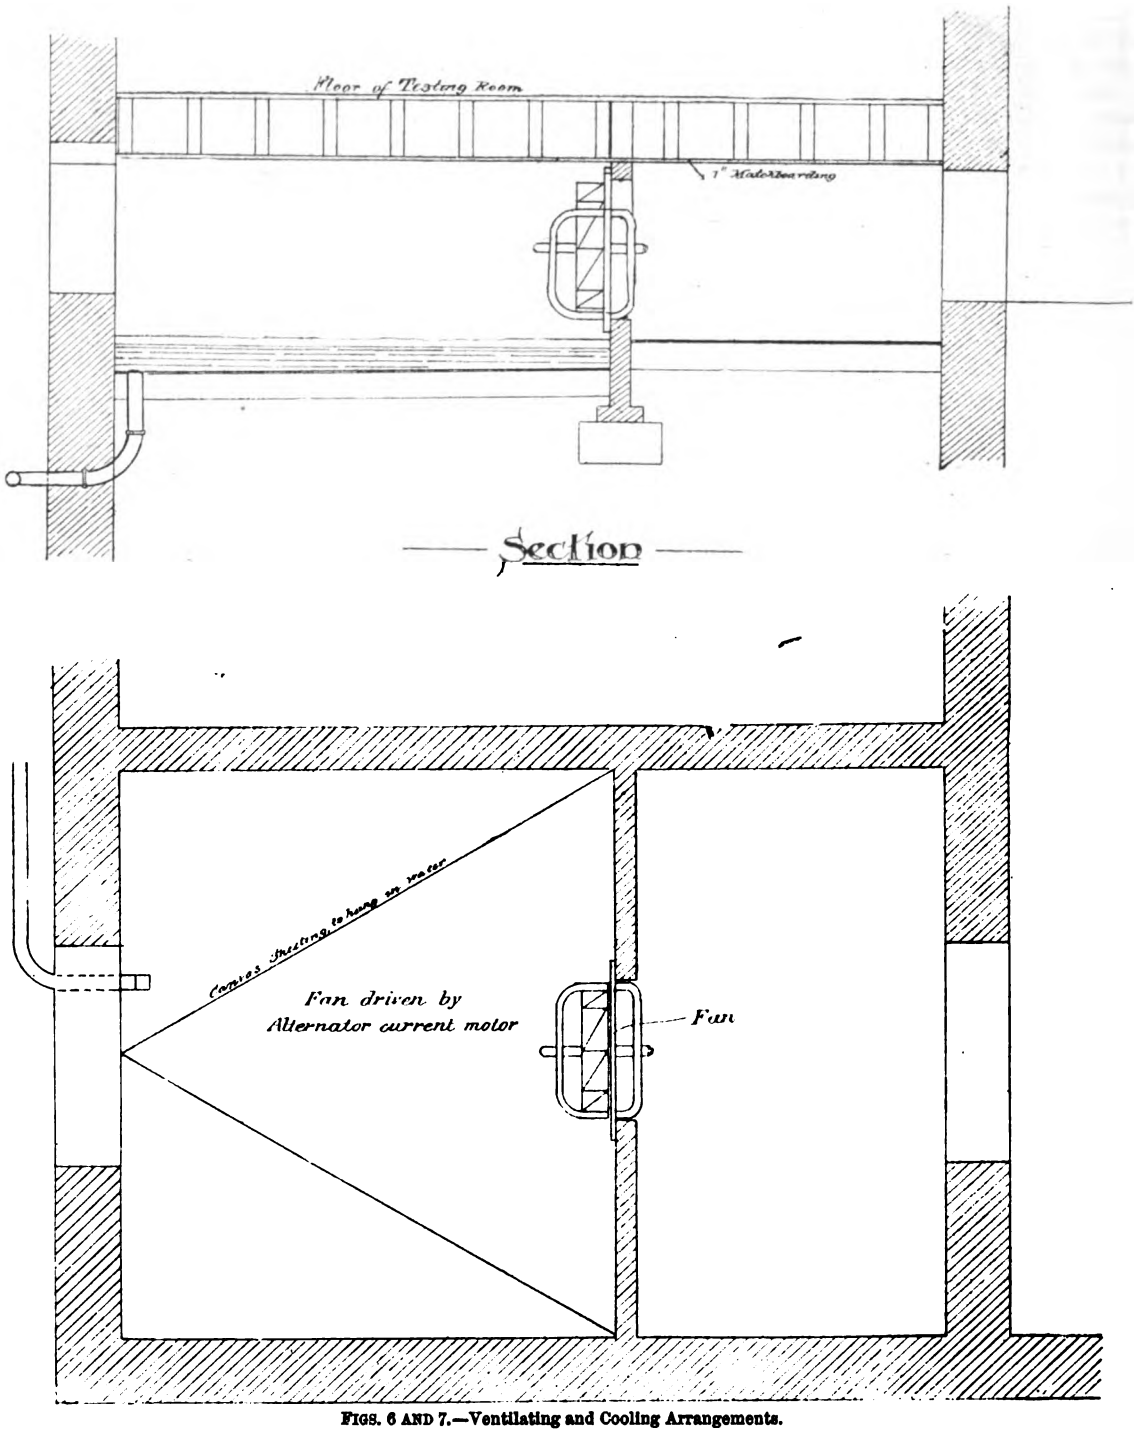
The other operation referred to is the manufacture of manure in the building just showing between the destructor, on the left-hand side of Fig. 2, and the electric lighting station on the right. The fine ashes falling through the fire-bars of the destructor are mixed with the deodorised sludge from the sewage outfalls. In this way a manure is made which commands a ready sale.

The system of charges has been carefully gone into, as will be seen by the following extract from the "condition of supply" fixed on a liberal and fair basis by Mr. Hall.

The price of electrical energy will be 6d. per Board of Trade unit. (At 6d. per Board of Trade unit an 8-c.p. lamp costs about one-fifth of a penny per hour, and a 16-c.p. lamp about one-third of a penny per hour.) Customers' accounts will be made up quarterly, and payments must be made at the Municipal Offices; 5 per cent. discount for cash will be allowed on accounts paid within 21 days, and in case of non-payment within 28 days the Corporation may refuse to continue the supply. At the end of every municipal financial year, which is on March 25, the total bill of every customer will be credited with rebates on a scale of which the following are examples, intermediate values being in proportion.

Greatest rate of consumption of energy in watts.	Rebate in proportion to the number of Board of Trade units taken during the year.							
	2½	7½	12½	17½	22½	27½	32½	37½
100	45	60	75	90	105	120	135	150
500	225	300	375	450	525	600	675	750
1,000	450	600	750	900	1,050	1,200	1,350	1 500
2,000	900	1,200	1,500	1,800	2.100	2,400	2,700	3,000
5,000	2,250	3,000	3,750	4,500	5,250	6,000	6,750	7,500
10,000	4,500	6,000	7,500	9,000	10,500	12,000	13,500	15,000

Take for an example the consumer whose maximum load is 1,000 watts. If he has his full load on for some 1,050 hours he gets a total allowance of 22½ per cent. plus 5 per cent. for cash, which will reduce the charge from 6d. to 4·35d. per unit. Again, should he use his lights for 1,500 hours he will get 42·5 per cent. rebate, only paying 3½d. per unit. (That some consumers use as much as this would not be very extraordinary.) If he used his full load from sunset up to 10 p.m., that would account for 1,456 hours, and even with 1,500 hours' lighting the load-factor would only be 17 per cent., whereas we know of at least two places in London where



FIGS. 6 AND 7.—Ventilating and Cooling Arrangements.

Digitized by Google

the load-factor is over 20 per cent. In this scale of rebates the Corporation give the light on the best terms to its most paying consumers, but the rate may tend to keep down the total number of lamps installed. We do not doubt, however, that it will stimulate the increase of the total units supplied. As a concession to small consumers, Mr. Hall has induced his committee to give up the customary meter rents. This charge for meters would hardly be felt by large consumers, but in small office installations it often exceeds the charge for current.

We believe, from local evidence, that the light is being well taken up in Cheltenham. The supply was commenced early in April, and in the experimental period, lasting till May, no charge was made for light. The liberal inducements held out to consumers should ensure a speedy increase in the power required. We shall not be surprised to hear next November that new machinery in larger units is required to supply the winter load. We understand that the total cost of the whole of the plant will come just within the £16,000 borrowed.

The electric lighting works were handed over to the Electric Lighting Committee by the contractors on Thursday, May 16. In commemoration of the completion of the station, the chairman and members of the committee entertained a large representative company to dinner at the Plough Hotel, Cheltenham, in the evening.

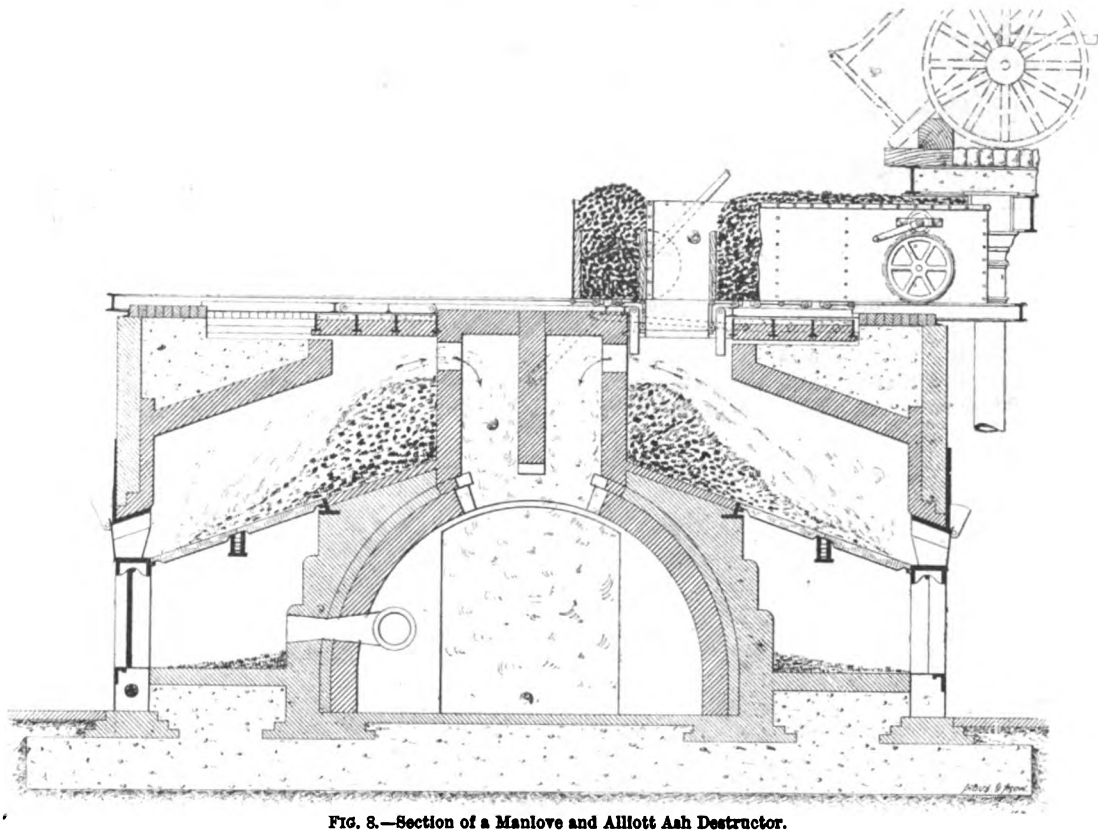


FIG. 8.—Section of a Manlove and Alliott Ash Destructor.

Buildings.

The whole of the designs for the buildings were prepared by Mr. Hall. There is no attempt made to attain external artistic beauty, but the general appearance is neat. The internal arrangements have been constructed with reference to practical requirements only, and no expense has been spared in the serviceable details, but the final ornamentation of the walls by panelling, etc., will not be carried out at present. The building contract was given to Messrs. Malvern and Son, of Cheltenham. The foundations, as will be seen by Fig. 3, had to be carried down some 16ft. to get on to firm soil.

General Description of the Works.

As previously stated, the central station stands on surplus land of the site (Fig. 1) acquired by the Corporation for the erection of the refuse destructor. It adjoins the Midland Railway Company's line near High-street, with which it will be ultimately connected by a siding. On approaching the works (Fig. 3) from Arle-road, the first points that strike the observer are that architectural effect was not one of the aims of the designer, and that there is no chimney-stack in immediate connection with the building. This latter point is explained by the fact that the boiler flues are led into the destructor chimney, the existence of which was one of the economic reasons which decided the adoption of the site. The chimney is about 70ft. distant from the south side of the building, and the furnaces are connected with it by means of an underground flue some 4ft. 6in. by 4ft. in section. The boiler-house is open on two sides, on the one side ample room being left for all probable extension. Two Galloway boilers are at present fixed, the working pressure of the steam being 120lb. to the square inch. In addition to these two, there is the boiler in the destructor, which it is estimated will yield 50 h.p. or 60 h.p. from the heat of the refuse furnaces—a source of energy otherwise wasted. The steam from this boiler, as well as from the two in the boiler-house, is led into a main ring of 6in. diameter, from which the steam is again distributed to the engines. A door by the boiler-house leads into the main passage 40ft. long, from which the workshop, store-room, and general office open on the right, and at the opposite end the engine-room; the flue, on its way from the boilers to the chimney, passes under the floor of this passage.

The engine-room is a lofty room, 25ft. wide, with a present length of about 60ft. As in the boiler-house, so here provision has been made for unlimited extension towards the west side of the building—a temporary match-board partition closing the end. The floor of the engine-room is of wood paving on concrete. There is a platform 3ft. wide and 3ft. high along two sides of the room from which the operations may be overlooked. On entering, one faces the condensing plant (by Belliss and Co.). This plant is sufficient for condensing the steam from the three engines at present in position. Well water, of which a good supply is found on the site, is used for condensing purposes, but there is also connection with the river-water main, from which the boilers are supplied. All the engines exhaust into one large main. Should the condensation not be sufficient from any cause to deal with this exhaust, an automatic valve, designed by Mr. Kilgour, is opened by the excess pressure, and allows the steam to exhaust into the open.

The engines are of the well-known Willans high-speed

Digitized by Google

type, the large set being of the I I type, and the two smaller sets of the G G type. They are direct coupled on common bedplates to Siemens alternators by means of buffer spring couplings, Fig. 11. The foundations for the whole building and for the machines have had to be carried down some 16ft. through sand and gravel into the clay bed. The exciters are placed on the same shaft as the alternators, the armatures being of the over-hung type, requiring no outside bearing. These exciters are series wound, and are said to afford means of regulating easily the station voltage from the normal 2,000 volts up to as much as 2,500 volts.

in the recess formed by the driving platform, which runs the full length of the engine-room.

The switch panels, of which there are six at present, are supported in the arches on the north side of the building. A lean-to gallery, 5ft. wide, is constructed on that side of the building, which affords easy and convenient access to the connections (Fig. 5). In their endeavour to procure absolute safety, the designers of this station have, we consider, erred on the careful side. They have boxed the back connections in with wood panels, which, although easily taken down, prevent the ready inspection of these parts

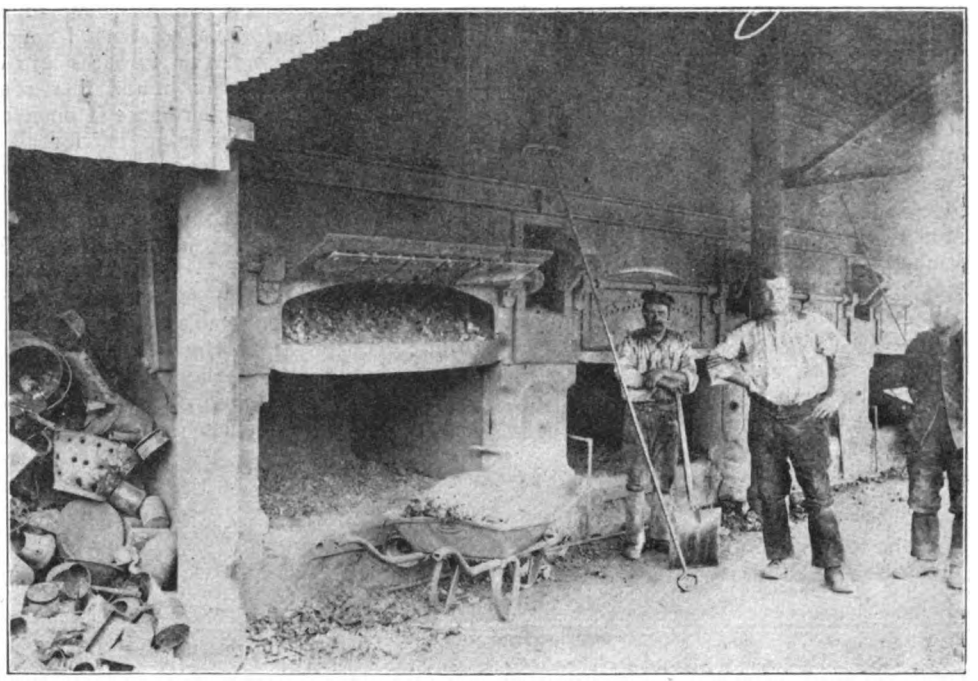

FIG. 8A.—View of Refuse Destructor at Cheltenham.

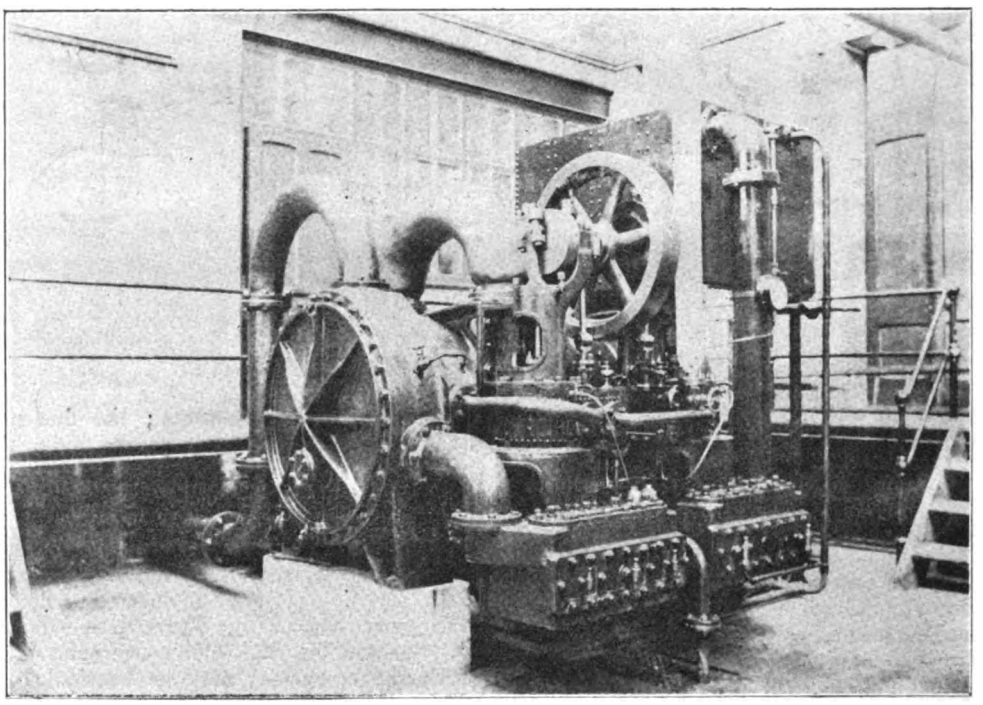

FIG. 9.—Bellias Condensing Plant and Feed Pumps.

The general arrangement of the machinery in the engine and boiler rooms will be seen from the plan and elevation, Fig. 3, and from Fig. 4, which was taken from the west corner of the engine-room. The steam and exhaust pipes are not shown in these views, but the steam-pipes are supported overhead in such a way as to allow for expansion. The exhaust pipe is placed on the floor, and is laid also, in case of a fault occurring, the wood would be ignited by the arc, and then to remove the panels will be a dangerous operation. We do not approve of making the back of a switchboard too inaccessible or safe, as such precautions breed carelessness in the attendants.

For cooling and ventilating the engine-room, Mr. Hall has devised a method illustrated in Figs. 6 and 7. The air

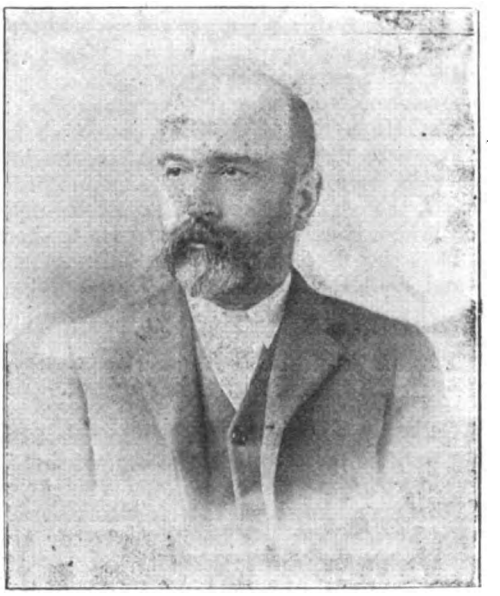
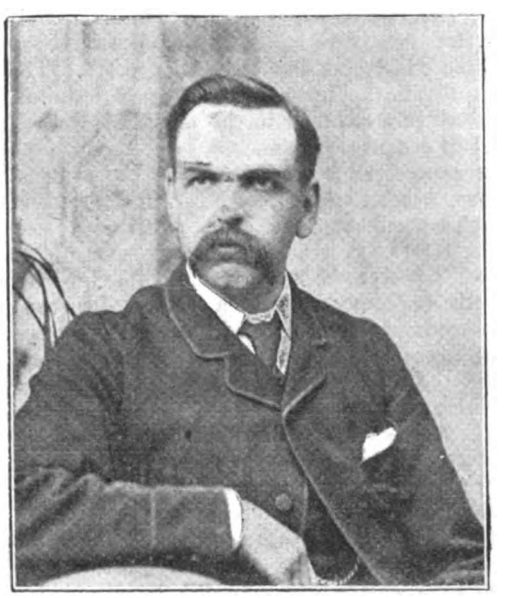
ALDERMAN WETHERED, F.G.S., F.C.S.,
Mayor of Cheltenham.



ALDERMAN NORMAN,
Chairman of the Cheltenham Electric Lighting Committee.

CHELTENHAM PROMENADE

MR. M. H. KILGOUR, A.I.E.E.,
Borough [Electrical Engineer.]



MR. JOSEPH HALL, A.M.I.C.E.,
Borough Surveyor and Engineer, Designer of the Cheltenham Electric Lighting Station

Google

is forced by means of a fan driven by an alternate-current motor through a canvas screen, kept moist by dipping in water. The apparatus is not yet at work, but the engine-room has a north aspect, and does not get unduly hot under the present working conditions.

The seven-ton overhead travelling crane was constructed by Messrs. Humpidge, Holborow, and Co., Limited, of Dudbridge, Stroud. It is of 25ft. span, the height from floor to rails being 19ft. 2in. The main girders are of steel joists, the end carriages of steel channels bolted to cast-iron bridge pieces. All motions are worked by hand chains from the floor below. The hoisting motion is of single and double purchase, fitted with brake and pawl gear for lowering purposes, and is capable of being operated by one man.

Steam Generating Plant.

Two Galloway boilers are provided, each 24ft. long by 7ft. diameter. They are capable of evaporating 5,000lb. of water per hour, with average coal and draught, which will drive 250 indicated horse, with an engine consuming 20lb. of water per horse-power per hour; and they are suitable for 120lb working pressure, the shell plates being $\frac{5}{8}$in. thick. The shells are 24ft. long by 7ft. diameter, and the longitudinal seams are butt-jointed with inside and outside cover strips secured by four rows of rivets. The interior consists of two furnaces joining into one Galloway flue. The furnaces are 2ft. 9$\frac{1}{2}$in. in diameter, solid welded longitudinally and flanged transversely by machine. They are united behind the fire bridges into one flue. The flues are supported by 28 Galloway cone tubes, all interchangeable, and with the flanges square to the centre line of tube, thus putting less strain upon the material during manufacture. Four patent pockets are fixed in the flue to divert the flame amongst the cone tubes, also two patent expansion pockets at the back end to prevent the undue escape of the heated gases, and to give the necessary space in the end plate for expansion and contraction. The furnaces and flue are provided with solid-welded angle rings for attachment to the ends. The boiler ends are solid, rolled in one piece $\frac{5}{8}$in. thick. The feed-valve is 2$\frac{1}{2}$in., the valve loose from the spindle so as to act as a check or non return valve, and to be set down by means of a hand-wheel and screw, also a connecting T-piece outside and perforated pipe inside the boiler for effectual distribution of the water. The safety-valves are one 4in. knife-edge lever safety-valve, with graduated lever and weight, and one lock-up spring safety-valve. The steam junction valve is 6in. (branch pattern), fitted with gunmetal valve and seating.

Fryer's Ash Destructor.

The other source of steam power is the ash destructor, which is explained above, and is placed in a building near the electric lighting station. These destructors were made by Manlove, Alliott, and Co., of Nottingham, and have been in use for some years. The steam up to the present has been used chiefly for disinfecting purposes. The whole of the linen from the fever and small-pox hospital has been disinfected in a chamber in the chemical works (shown in Fig. 2) by means of steam.

The general construction of the Fryer cells made by Manlove, Alliott, and Co. is shown in Fig. 8, but the Fryer cells at Cheltenham have been constructed side by side. Each cell forms a separate furnace, comprising a cavity enclosed by a reverberatory arch lined with firebricks. The cell is provided with a hearth for the reception of the refuse to be burned, from which it passes into the furnace proper. The passage of the material to the front is facilitated by arranging the fire-bars in an inclined position, which also renders easy the removal of the clinkers. The top of the destructor constitutes a platform, an opening over each cell being provided for the reception of the mixture of sludge and ashbin refuse, which is shot through the opening direct from the dust-carts. It will, of course, be understood that the opening for the admission of refuse is divided from that for the exit of gases, the division being formed by a wall, whilst a bridge is provided to prevent the refuse heaped on at each charge from getting into the flue immediately below. Special openings are provided for the direct introduction upon the burning mass of infectious mattresses, diseased meat, dead cats and dogs, etc. The furnaces when once lighted are kept at work by the refuse itself. In order to prevent inconvenience to the stokers through the fine dust being blown about, a concave pit is constructed under the furnace bars. This pit is partly filled with water, and the fine dust falling therein is removed when the fires are drawn. The clinkering is done at intervals of about two hours, and the quantities of clinker and fine ash vary in proportion to the kind of material burned. The clinker is used in the manufacture of concrete, for tar paving, for building, and path making purposes, hard core for roads, artificial stone when ground up as sand, and for the construction of walls. There are eight of these cells at Cheltenham, and a cremator.

Condensing and Feeding Plant.

These parts of the machinery were supplied by Messrs. G. E. Belliss and Co., of Birmingham. The condensing gear is shown in Fig. 9. This plant includes, besides double-acting circulating and air pumps, a double-acting feed-pump, worked by an eccentric on the crankshaft. The water passes twice through the condenser tubes, the steam being outside them. The condensed steam is discharged by the air-pump into the hot-well placed above the level of the condenser. In the hot-well is arranged an apparatus for removing the grease from the feed water. The following are a few of the leading dimensions of this plant:

Diameter of high-pressure cylinder	6in.
,, low ,, ,,	10$\frac{1}{2}$in.
Length of stroke	6in.
Diameter of double-acting air-pump	12in.
,, ,, ,, circulating-pump	12in.
Cooling surface	700 sq. ft.
Diameter of feed-pump	2$\frac{1}{4}$in
Length of stroke	7in.

In the boiler-room an additional feed-pump is provided as a stand-by. It is of the Worthington type, but was supplied by Belliss and Co. No economiser has been fixed as yet, but the necessary flue accommodation has been provided, so that one can easily be installed. The feed-pipes are in most cases duplicated, and so supplied with valves that no single fracture would necessitate shutting down for want of steam.

Steam and Exhaust Pipes.

The whole of these have been erected by the Corporation engineer, the execution of the work being under the supervision of Mr. Kilgour. The main steam-pipe is constructed on the ring principle, but a new departure has been made in placing that part of the ring usually placed in the engine-room in the space over the economiser flues. The reason for this arrangement is a wish on the part of Mr. Hall to have as few steam joints in the engine-room as possible. This is an advantage in many ways, but any defective joint will hardly be as quickly noticed in the unused space between the boiler and engine rooms (Fig. 3) as if the steam-pipes were in the engine-room itself. With frequent inspection, however, any defects should be noticed before they become serious. Hopkinson's straight-through parallel slide-valves are used throughout, and placed in such positions that the possibility of a failure of light through a defective steam-pipe is minimised. All the joints are made with asbestos sectional packing. The whole ring main is suspended from brackets fixed in the walls by means of attachments allowing lateral movement in either direction. In this way the need of expansion joints is largely overcome. The steam-ring is drained by steam-traps, and one of Geipel's steam-traps is also connected to each engine steam-separator. The exhaust-pipe is laid on the floor, as explained in the general arrangement of plant. In the main pipe there is placed an automatic valve, designed by the electrical engineer, for opening the exhaust system to the air should the pressure in it rise above that of the atmosphere: a section of this is shown in Fig. 10.

Digitized by Google

A is a gunmetal bush screwed inside and made square outside, and capable of sliding in the outer bush, which is held in position by the two studs at the top. G is the gunmetal valve spindle. O is the outlet, the inlet being at

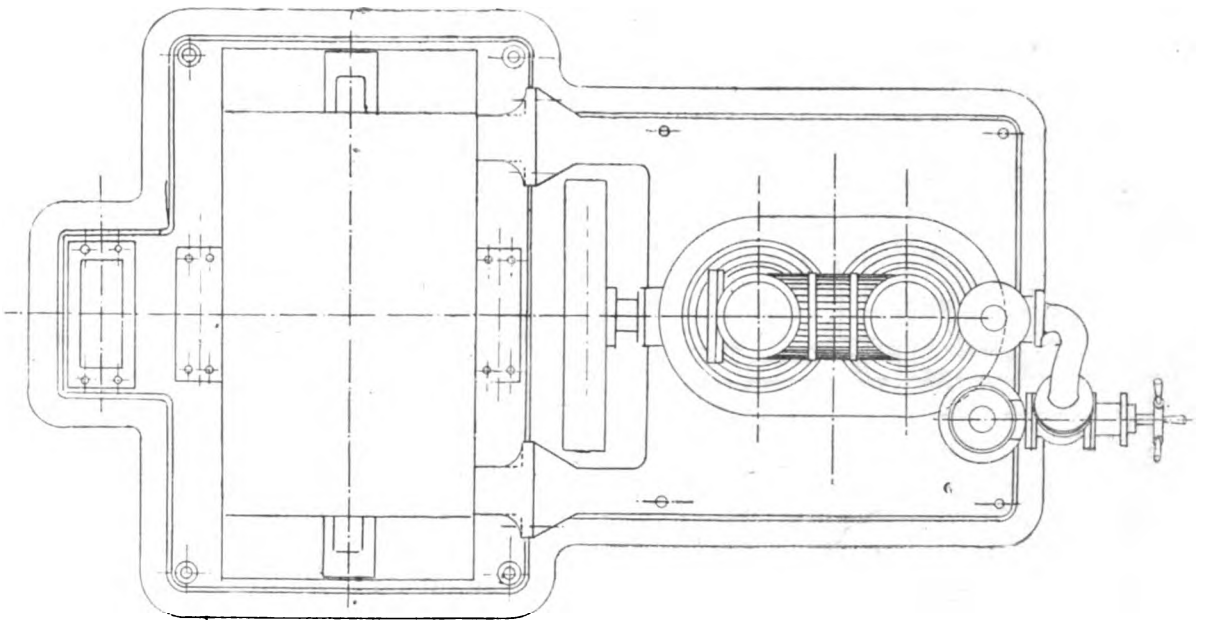


FIG. 12.—Plan of 33-K.W. Steam Alternator.

the underside of the valve. The principle of the valve is apparent from the illustration. Should the pressure in the exhaust-pipe exceed that of the atmosphere the valve rises, the square bush sliding inside the outer brass bush; the valve can also be opened by hand by means of the milled wheel, W.

The Engines.

These are of the well-known Willans central-valve gear type. There are three of these engines at Cheltenham—one of the I I size, capable of giving 200 i.h.p. at 350 revolutions per minute; and two of the G G size, capable of giving 80 i.h.p. each at 460 revolutions. The steam pressure under which the first works is 105lb., while the remaining two are supplied at 65lb. per square inch. All three engines are coupled direct to Siemens alternators. The cylinders of the I I engine are 20in. and 14in. in diameter, and its stroke is 9in., while those of the G G engines are 14in. and 10in in diameter, and the stroke is 6in.

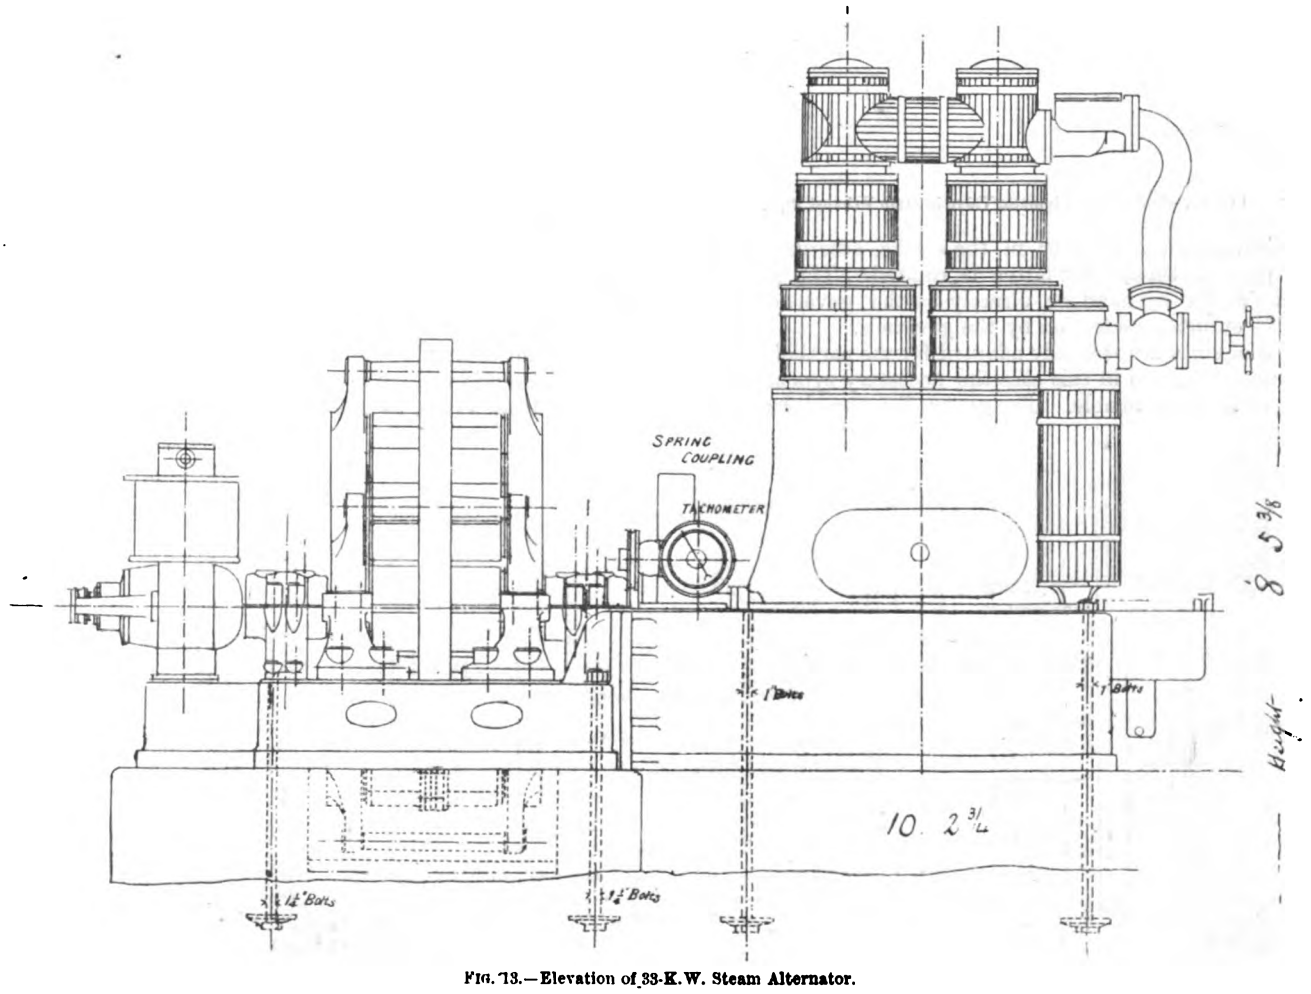

FIG. 13.—Elevation of 33-K.W. Steam Alternator.

The variable expansion gear is arranged as follows: The steam gland in the high-pressure cylinder is made movable and takes the form of a sleeve with oblique ports cut in it. There are corresponding ports in the hollow piston-rod,

Digitized by Google

Cut-off is effected in the manner usually adopted in these engines—by the passage of the ports in the hollow piston-rod into the gland out of the steam-chest. The point of cut-off is varied by rotating the gland sleeve upon its axis, the ports in the piston-rod meeting the edges of those in

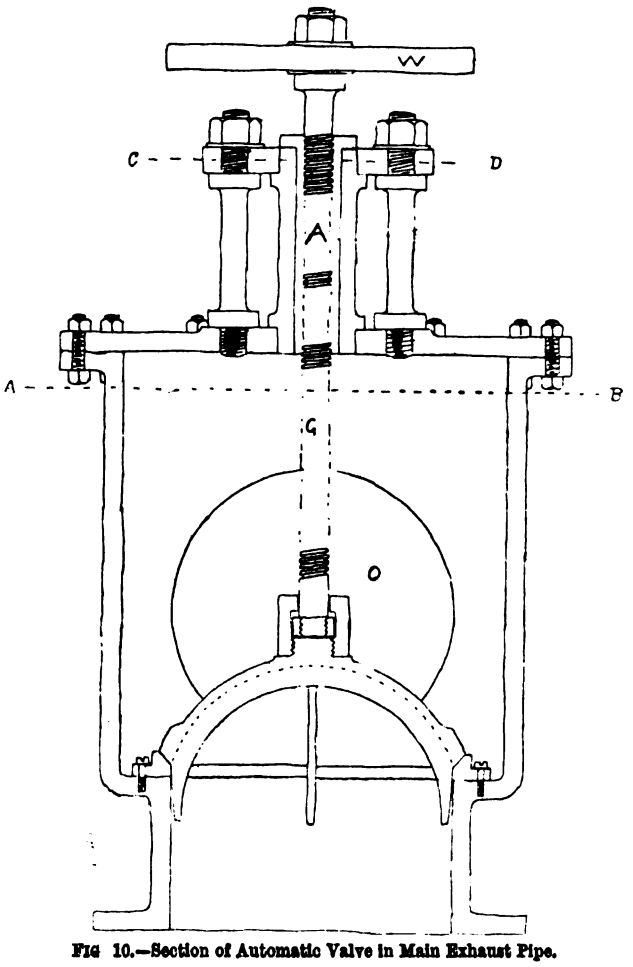

FIG 10.—Section of Automatic Valve in Main Exhaust Pipe.

the sleeve earlier or later in the stroke, according to the direction in which the latter is rotated. The sleeve is moved either by hand or directly by the governor, or by a relay cylinder controlled by the governor.

The engines are specially adapted for the parallel running of alternators, and in this case the necessary synchronising current is inappreciable. The reason for the difference in the specified steam pressure in the two sets is as follows: The smaller engines have to be sufficiently large to develop the power required for driving the small alternators when the steam pressure is not less than 65lb. above atmosphere and the back pressure not more than 6lb. absolute. The large engine need only be large enough to develop its rated power with a pressure of not less than 105lb. above atmosphere and a back pressure of not more than 6lb. absolute. All engines are made strong enough for a working steam pressure of 130lb. to 140lb. above atmosphere in their steam-chests. The reason of this curious diversity between the engines is very simple:

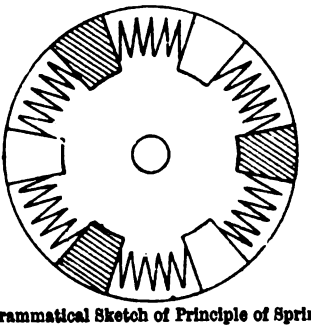

FIG. 11.—Diagrammatical Sketch of Principle of Spring Couplin .

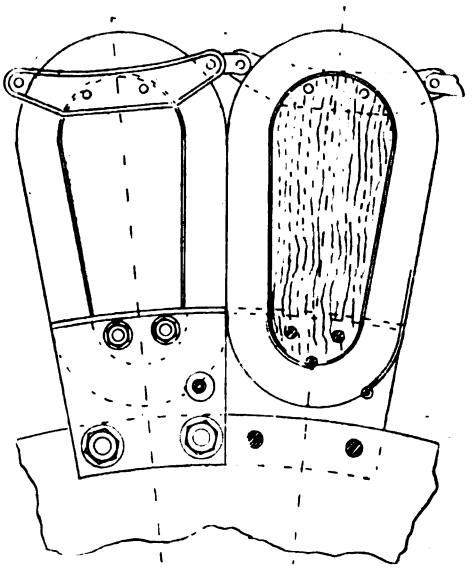

FIG. 15.—Coils of a Siemens Alternator.

the small engines are about as much as the ash destructors are able to supply steam to, and the cylinders, therefore, have to be large enough to develop the power required with the pressure available from the ash-destructor boiler, which is 80lb. at most, or, allowing a margin, 65lb. at the engines. The large engine will always be worked from Galloway boilers, at from 115lb. to 120lb. pressure, because when it is worth while to run this engine the load will be too much for the ash-destructor boiler. All the engines will be worked from the Galloway boilers when the load is above 100 kilowatts. Mr. Kilgour estimates from some rough tests already made that the destructor boiler will evaporate about 1,000lb. of water per hour, and thus is capable of driving one of the 33-kilowatt sets.

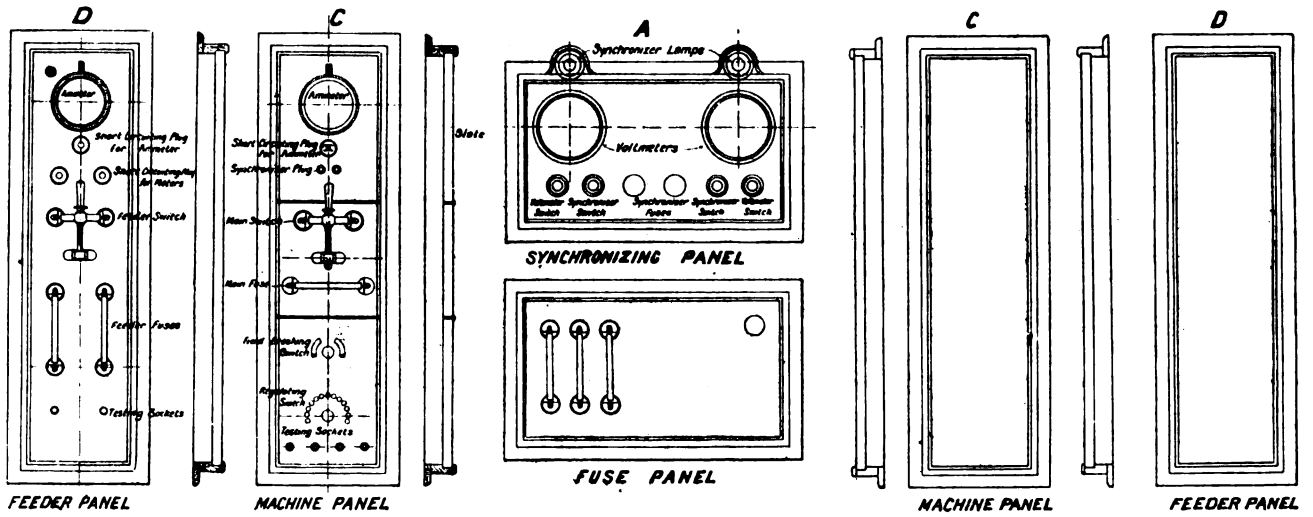

FIG. 16.—View of the Cheltenham Switchboards.

Digitized by Google

Alternators.

These are of the now well-known type manufactured by Messrs. Siemens and Co., of Woolwich. The larger alternator is designated by the mysterious symbol "W 32," which is compiled from the fact that W stands for alternator in German, and 32 is the number of poles. This machine gives 50 amperes at 2,200 volts when running at a speed of 350 revolutions, the frequency thus being 94 ⁓ per second. The smaller alternators are "W 24"'s, having 24 poles, and giving 33 kilowatts at a speed of 466 revolutions per minute. They are direct driven by the engines by means of a specially designed spring coupling. The details of this coupling, which have been of great assistance in other stations where there has been trouble with parallel running, are not available, but we understand that the general principle of the coupling is as follows: Two similar claw castings are provided, one attached to the engine shaft and one to the dynamo shaft, Fig. 11. Spiral springs are placed between the alternators' claws, and in this way a sensibly flexible drive is obtained.

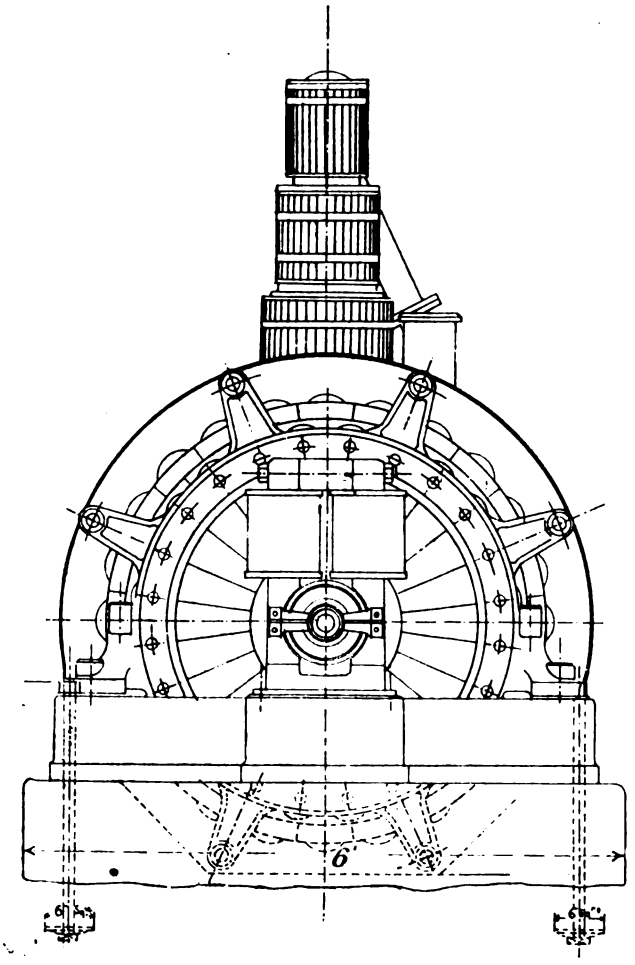

FIG. 14.—Side Elevation of 33-K.W. Steam Alternator.

The effect of this coupling, together with the steady running of the Willans engine, allows of parallel running without any sensible fluctuation of current.

The construction of the small alternators can be seen from Figs. 12, 13, and 14, the 110-kilowatt machine being of the same general type. The armature coils are wound on wooden formers, as shown in Fig. 15, and are composed of fine-stranded copper wire pressed into a rectangular form, after the usual method adopted by Messrs. Siemens and Co.

The mounting of the coil on to the wrought-iron disc which acts as the armature hub is effected in the manner shown in our diagrammatic sketch. The magnets are of wrought iron, and are mounted in cast-iron yokes, as shown in the general arrangements (Fig. 4), and the magnetising coils are connected to give alternately north and south poles. The usual Siemens collecting gear is used. The bearings are of special construction, with efficient lubrication. The larger steam dynamo is guaranteed to deliver, working at not less than three-quarters full load, not less than 560 watts per indicated horse-power, and each of the two smaller steam dynamos under the same conditions not less than 500 watts per indicated horse-power. Also, under the foregoing conditions of load, and with a steam pressure of about 130lb. per square inch (absolute) in the steam-pipe, and a back pressure not exceeding 6lb. per square inch (absolute) in the exhaust-pipe, the consumption of steam per indicated horse-power per hour is not to exceed 20lb. for the larger and 23lb. for each of the two smaller steam dynamos. The exciters are all of equal output, and are Siemens's "H D 10 6½" series dynamos. These are constructed on the overhanging principle, to avoid the necessity of a third bearing. The armature is attached to the extension of the alternator shaft. With constant-speed machines the series excitation allows of more ready regulation, although the resistance provided for regulating purposes has to be of a much larger section than when the exciters are regulated on the shunt system.

Switch Gear.

The switchboards have been made by Messrs. Siemens Bros. (Fig. 16). Six panels have been supplied up to the present, consisting of two machine panels, two feeder panels, a fuse panel, and a synchronising panel. The connections are those usually adopted for parallel running. The high-tension switches and fuses are all of the Siemens approved type, and the men are liberally protected against accidental contact with the live metal.

Distribution.

The distribution is on the high-tension sub-station system, but in some cases transformers have been placed temporarily on the consumers' premises. All the mains in use at Cheltenham, both for the high-pressure feeders and the low-pressure distribution network, have been manufactured and laid by the Callender's Bitumen Telegraph and Waterproof Company, Limited, whose resident engineer on the work was Mr. G. Barnard.

FIG. 17.—Laying Mains at Cheltenham.

The main high-tension cable is capable of transmitting 350 h.p., or of lighting, say, 8,500 8-c.p. lamps. It is drawn into paper tubes, of the Hawtayne system, embedded in a layer of bitumen, which, in its turn, is laid in Portland cement concrete—this can be seen in Fig. 17. The high-tension mains runs along High-street and St. George's-place to the chief distributing station, at the corner of Manchester-street, opposite the free library. Hence the current is distributed to the various underground sub-stations throughout the town, where the high pressure of 2,000 volts is reduced to 100 volts. A system of low-tension mains is laid from these sub-stations wherever the demand warrant the necessary expense. In other places, as in a division of the High-street, between New-street and Clarence-street, with St. George's-place, the consumers are supplied by a high-pressure main, with transformers on their own premises. Of the five or six sub-stations contemplated three are now practically complete, these being situated in High-street opposite North-street at Cambray, and at Ormond-place.

DUBLIN TRAMWAYS.

We have before us a copy of the report which Mr. Robert Hammond has submitted to the directors of the Dublin United Tramways Company with reference to the proposed introduction of electric traction upon its lines. After a short comparison of the three available mechanical systems of traction — steam, cable, and electricity—Mr. Hammond concludes that, so far as Dublin is concerned, the only advisable method of operation is by electricity, and that of electrical systems the only commendable one is that which employs elevated conductors and trolleys. Mr. Hammond conclusively demonstrates that no danger can result from the use of elevated conductors and a potential of five hundred volts, supporting this conclusion by quotations from high American authority and by the statements of local authorities of the district served by the South Staffordshire tramways. An interesting statement is that made by Mr. Clifford, manager of the Law Accident and Contingency Society, to the effect that when the South Staffordshire tramway was first insured against "third party risks," the same rates were charged as are usual for the insurance of steam tramway companies, but that owing to immunity from accidents the premium had been diminished, till it is now less than half the steam tramway rate. This testimony is most convincing. The report then proceeds to enumerate various objections which have been raised to the overhead conductor and trolley system, mainly with reference to the unsightliness of span wires in the public streets. This line of objection is disposed of by Mr. Hammond by reference to the system now employed by the South Staffordshire tramways, which were constructed by the Electric Construction Corporation, Limited, and which system of line construction is also in course of installation at Bristol by the British Thomson-Houston, Limited. This method of construction, in which the trolley wires are supported at a considerable distance from the track from brackets attached to poles along one side only of the roadway, is accepted by Mr. Hammond as the best, principally for the reason that it interferes less with the progress of fire-escapes along the street than might be the case where span wires crossing the street at intervals are employed.

On this point we take issue with Mr. Hammond, and it would seem to us that he proposes the adoption of the less efficient method of line installation as the easiest way out of a difficulty with local authorities. There certainly is no reason why an existing type of fire-ladder should be perpetuated indefinitely and always remain of a given height, when it would be the simplest of mechanical expedients to decrease the height of the permanently standing portion of the ladder to such an extent as would enable it to pass easily under wires twenty-one feet above the roadway. We might go further and say that these extremely cumbersome fire-escapes are wholly out of date, and that instead of sacrificing the cross-suspension method in order to facilitate their passage, it would be far more advantageous to both fire department and tramway company

Digitized by Google

to introduce the horizontal ladders nearly universally used both in America and on the Continent. If American and European practice in electric traction has demonstrated anything, it has conclusively proved that economical and efficient operation can best be secured by a trolley wire over the centre of the car roof, and that every departure therefrom is necessarily accompanied by increase in cost of maintenance and decrease in the efficiency of the service. Many thousands of miles of track and some thirty-five thousand motor cars are now successfully operated under these conditions, while operation by a side wire and a side-acting trolley has the support of but one single instance, and that a line constructed under the necessity of complying with special local conditions. We would, moreover, call attention to the eminent danger of experimenting on the tramways of a great city with data obtained from a small country installation, when these results are distinctly at variance with those obtained on all the great electrical tramway installations which are now in use. In the South Staffordshire tramway equipment a specific difficulty was ingeniously overcome, but it would seem unwise to suggest that such an expedient, however ingenious, should be followed where the necessity for its introduction is not apparent. It is our opinion that wherever a line of track does not run close along the kerb line, the span wire supporting the trolley wire centrally over the car is vastly preferable to such construction both in appearance and in certainty and economy of service. Where, as in many continental installations, the span wires can be supported by rosettes attached to the walls of buildings along the route, all reasonable objection to them entirely disappears. Of all methods of supporting the trolley wires for a double-track tramway in broad streets, the centre pole between tracks is by far the most satisfactory from every point of view.

There is another point on which we do not quite agree with Mr. Hammond. He states that "the problem of generating electricity for lighting and for traction are almost identical." In this we certainly do not concur, and we think that all those having experience in electric traction will agree with us when we say that to design an electric tramway power-house on the same lines as would be followed were an electric lighting station in question, would prove financially disastrous. The choice of units, type of dynamos, engines, boilers, and arrangement is very different in a traction plant to what it would be in a lighting station. This experience has been bought and dearly paid for in America as well as on the Continent, and it is to be hoped that English tramways desiring to substitute electric traction for other motive power will profit by the experience that is at hand, and not insist upon paying a heavy price for original and individual experimentation. We wholly agree with the closing paragraph of Mr. Hammond's report, in which he says that from the point of view of the citizens, the corporation, and the tramways the introduction of electric traction into Dublin is most desirable. We will go further and say that the introduction of this mode of traction is desirable in every English town, and we look forward to a day not far distant when tramways equipped with the most modern mechanical power will relieve the crowded thoroughfares of the Metropolis itself.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

CITY AND GUILDS EXAMINATION.

SIR,—Notwithstanding your note to the contrary, I still think this question (No. 6) has not been answered correctly. Mr. Shepherd says the mean current along the line is 100 amperes. May I ask why? The question says plainly that one ampere is required for every 10ft. of frontage, and as there are 2,000ft. frontage, 200 amperes are required. I think, also, you were in error in saying that Mr. Shepherd's answer would have taken full marks. It certainly would not, as the working by which he gets the current is not shown, nor the reasoning by which he arrives at ·02 as the resistance of the circuit. This would certainly be marked "deficient." I append a solution I posted last week in Edinburgh, but which I presume has not reached you or has been mislaid:

(*a*) Current required $= \frac{2,000}{10} = 200$ amperes.

Total resistance between first and last lamp $= \frac{\text{fall in volts}}{\text{current}} = \frac{2}{200} = \cdot 01$ ohm.

But the resistance of a bar of copper 2,000ft. long 1 square inch section = ·008 × 2 = ·016 ohm.

·01 ohm : ·016 ohm :: 1 square inch : x square inch,

$\therefore x = 1{\cdot}6$ square inches. —*Answer.*

(*b*) The supply is now midway and the distance between the first and last lamp is 1,000ft.

$\therefore$ Current required is $\frac{1,000}{10} = 100$ amperes.

As before, resistance $= \frac{\text{potential difference}}{\text{current}} = \frac{2}{100} = \cdot 02$ ohm,

and the resistance of 1,000ft. of copper bar 1 square inch = ·008 ohm,

$\therefore$ ·02 : ·008 :: 1 square inch : x square inch,

$\therefore x = \frac{\cdot 008}{\cdot 02} = \cdot 4$ square inch.

There is no mention of a return wire in the question, and we have no right to assume one. The return may be "earth."—Yours, etc., JAMES MCLURE.

29, Stirling-street, Airdrie, N.B., May 12, 1895.

SIR,—The reason I took the total instead of the mean current was that in the question no reference is made as to the distribution of the current along the mains. It says, "Current is required along a street 2,000ft. long at the *rate* of one ampere per 10ft. of frontage." Should the bulk of the lamps be alight at the far end of the mains while only one or two are alight at the station end, then my calculation would practically apply.—Yours, etc.,

HALDANE G. COTSWORTH.

14, Station-road, Swindon, May 15, 1895.

FIRE RULES.

SIR,—As certain statements have been made with regard to electrical installations placed up in consumers' premises that may give rise to erroneous impressions and cause needless alarm, I beg you will be courteous enough to spare me a portion of the valuable space in your columns to enable me to say a few words upon the subject.

So far from electrical installations being now placed up in buildings in a worse manner than formerly, my experience is that every year shows an improvement in the way the work is done; and that, taking electrical installations as a

Digitized by Google

whole, the work is better put up now than it has ever been. So far as I can learn, there is no country in the world where the installations inside buildings are to be compared to those installed in England.

With regard to fire danger, I have to say that the Phœnix Fire Office has not yet had to pay a shilling of loss with regard to any electrical installation of any kind when the work has been placed up in accordance with its rules, notwithstanding the enormous number of buildings containing electrical installations that have come before that office, comprising not only private houses, but all kinds of public buildings, mills, factories, workshops, warehouses, shops, etc.; and this immunity from loss has not merely been for a year or two, but extends back to the commencement of electric lighting in the beginning of 1882—over 13 years ago. A more satisfactory condition of things from a fire point of view it would be impossible to conceive.

It is with great surprise I learn that the Institute of Electrical Engineers is about to issue new rules for electrical installations inside buildings. I have to state that the Phœnix Fire Office will not for one moment recognise any such rules if they be issued, and it is well that all electrical contractors, not only in London, but throughout the country should be fully aware of this.

The Phœnix Fire Office will not depart from the course that long experience has proved to be so safe, and will require, as before, that in any building insured with it the electrical work shall comply with its rules. It has the responsibility of paying for fire losses, and therefore it is absurd to think that it would agree to anything that might practically place the disposal of its funds at the mercy of the views of an outside body.—Yours, etc.,

London, May 16, 1895. MUSGRAVE HEAPHY.

ACCIDENT.

SIR,—An accident occurred to one of our men in connection with the electric lighting of this town, and as we notice that an erroneous description of the causes which led to the accident have found their way into the papers, we beg to give you what we believe to be the true facts of the case so far as we have been able to ascertain them.

Our man went up a ladder placed against a pole in order to fix some new insulators for a new circuit. He hooked a linesman's vice on to the steel suspending wire of the street-lighting circuit, which was then switched off. This steel wire was probably charged by induction from the neighbouring private lighting circuit, so that when our man placed his hand upon it, and touched the lightning conductor or transformer case which was connected to the earth, he received what is called a static shock, harmless in itself, but which probably caused him to lose his balance. He fell 20ft. and has received serious injuries, which are, we believe, entirely due to his fall, and not in any way connected with the static shock, but we hope he will make satisfactory recovery.—Yours, etc.,

(For Chelmsford Electric Lighting Company)

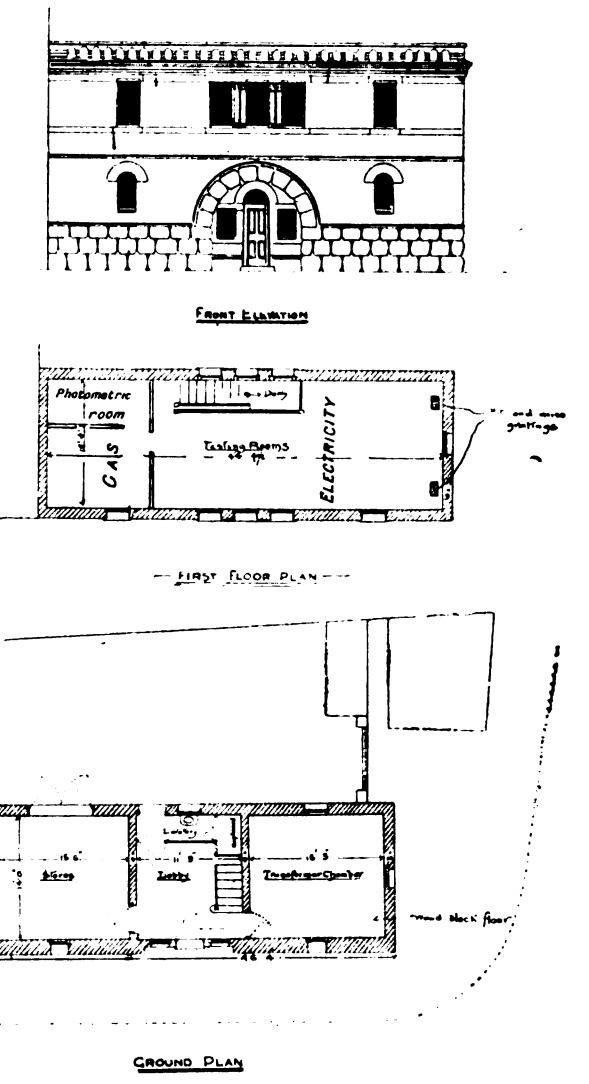
CHELTENHAM ELECTRICITY WORKS.

(Concluded from page 563.)

Cables.

All the cables used at Cheltenham are concentric. Both conductors are insulated, the dielectric consisting of bituminised fibre. A solid tube of lead is forced directly on to the outer dielectric under hydraulic pressure, and the cable is protected by a steel armouring where it is required for laying direct in the ground. It is only braided over the lead when required to be drawn into the conduits. The only difference in the cables used for high and low pressure current is in the variation in the insulation resistance provided, which is varied by the radial thickness of the dielectric.

The high-pressure trunk main connects the generating station with the distribution network ends at Manchester-street, where a sub-station has been constructed above ground.



FIGS. 18, 19, AND 20.—Views of Sub-Stations in Manchester-street.

The length of this main is 2,100 yards, and the section of the conductor used is 0·123 square inch. High-pressure mains run from the Manchester-street sub-station to smaller transformer stations throughout the town. The sections of these cables are either 0·062 or 0·020 square inch, according to the district they serve. As far as possible, all the high-pressure cables have been drawn into the lower ducts of the conduit, but in part of High-street it was found most convenient to use an armoured cable, which has been laid direct under the street.

All the low-tension distributing mains have conductors which are of 0·155 square inch section, and wherever possible the conduits have been utilised for their reception, armoured cables being employed only where the exigencies of the street work rendered this type of main more convenient. Special boxes were used in jointing the cables, which were also supplied by the Callender Company, who took great care in making the attachment to the mains.

Digitized by Google

Consumers have been connected with the distribution network at pits constructed in the run of the conduit, in which cast-iron boxes are set, and from which double-wire service lines are led into the consumers' premises. Fig. 17 shows the operation of laying the cables down the promenade.

The whole of the street work has been executed by the staff of the Corporation, under the direction of the borough electrician and his assistants. Consequently, not so many people have been employed at a time as would have been the case had the work been let, and for this reason the operations have been carried out with less rapidity than might otherwise have been the case.

Sub-Stations.

The largest sub-station is in Manchester-street (Figs. 18, 19, and 20) and is used for various other purposes as well. It is a two-storeyed, red-brick building, 46ft. 4in. long, with an ornamental coping. On the ground floor are the transformer-chamber, a storeroom, a handsome lobby, lavatory, etc., with wood-block floors. On the first floor are a large electrical testing-room, a small gas-testing chamber, and a darkroom for testing the candle-power and efficiency of electric and gas lamps. In the transformer-chamber, besides the transformers, there are the necessary high-tension connecting and fuse boxes, the switch gear, and various low-tension connecting gear. In this building the Corporation will keep a check both on their own officials and on all the illuminants supplied in Cheltenham. It is proposed to add an additional floor to this station, in order to provide accommodation for an attendant.

Transformers.

The transformers used in the sub-stations at Cheltenham were manufactured by the Brush Company. Two sizes are used—12 and 6 kilowatts. Mr. Kilgour tested these transformers at Loughborough, and the following is an abstract of his report: The insulation resistance was tested (*a*) between primary winding and case; (*b*) between secondary winding and case; (*c*) between primary and secondary. In every case the insulation resistance was above that specified, and the mean value was about 250 megohms. The transformers stood a pressure of 3,000 volts between primary and case.

The 12-kilowatt transformers had an average iron loss of 96 watts, which is only 0·81 per cent.—the magnetising current being 0·072 ampere, which is 1·2 per cent. of the full current. The power factor is thus 68 per cent. In the six-kilowatt transformer the iron loss equals 69·5 watts, the magnetising current 0·049 ampere. The regulation of both of these transformers was good, the voltage drop between full load and no load for the 12-kilowatt being only two volts and the six-kilowatt 2·5 volts. We congratulate the Brush Company upon the efficiency of these instruments.

The running of the machinery will be attended to by the contractors for one month before it is handed to the Corporation, and during this time the responsibility for a regular supply rests with Messrs. Siemens and Co., the machinery remaining at present in charge of Mr. Stanley Franklin, their representative, who has had charge of the whole of the work done by that firm, and has carried it out most successfully.

PROJECTOR MIRRORS.

Much discussion has recently taken place, especially amongst naval and military experts, concerning the relative merits of the Mangin and of the parabolic reflector. The degree of success achieved by Messrs. Schuckert and Co. has caused many to form an idea that the parabolic mirror must necessarily be the best for purposes of projection. When considering glass mirrors silvered on the back it would seem that this idea is erroneous, and the good results obtained by the Nuremberg firm appear to be attributable rather to the employment of comparatively short focal lengths, and to the use of automatic horizontal arc lamps, than to the particular type of mirror made by this firm. Until recently it was thought to be impossible to construct a mirror on the Mangin principle, and having a focal length of less than two-thirds of its diameter. Messrs. Sautter, Harlé, et Cie., of Paris, have, however, now succeeded in so far reducing the focal lengths of their Mangin mirrors as to admit of the use of horizontal projector lamps. They claim that the new type of Mangin mirror is superior to the parabolic mirror produced by their German rivals, and have clearly cited their argument in a pamphlet recently issued.

This question is an important one from a manufacturing point of view, as it is well known that our Government have from time to time been obliged to place valuable orders for projector mirrors with the firms above mentioned. We therefore give the following translation of the pamphlet referred to, and shall be curious to learn if the cata-dioptric principle of mirror construction first suggested, we believe, by Sir John Herschel, is as successful in practice as it is stated to be by the celebrated French manufacturers of the Avenue de Saffren.

SOME NOTES ON THE RELATIVE MERITS OF MANGIN AND PARABOLIC MIRRORS.

1. *Parallelism of the Rays.*—Taking the best-known type of Mangin mirror—viz., that of 60cm. diameter—the focal distances

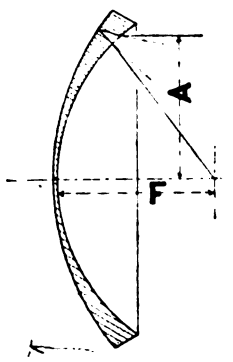


FIG. 1.

FIG. 2.

calculated and verified by experiment for various zones (*vide* Fig. 1) are as follows:

A.	F.
50mm.	318·2mm.
100mm.	318·3mm.
150mm.	318·3mm.
200mm.	317·8mm.
250mm.	317·8mm.
300mm.	318·0mm.

The differences between these are very small, and if the centre of the luminous crater be placed at a distance of 318·05mm. from the centre of the mirror, the focus of any portion of the reflecting surface will not fall on the axis further than ¼mm. from this point. This amount of aberration is less than that produced by the smallest accidental deformity of shape of the carbons. With a parabolic mirror, on the other hand, the aberration is greater, in consequence of the double refraction of the rays (*vide* Fig. 2) which in the case of the Mangin mirror is utilised to produce parallelism and to prevent aberration. Calculation shows that from this cause alone the aberration of a parabolic mirror amounts to 1½mm., or three times that of the Mangin mirror referred to above; and we may conclude that the aberration of a Mangin mirror is less than that of a parabolic mirror of the same diameter, and that in consequence the parallelism of the rays is more exactly obtained with the former than with the latter.

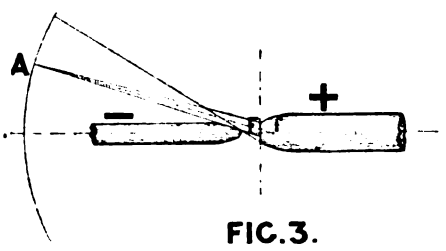

FIG. 3.

2. *Employment of Horizontal Lamps.*—With a horizontal lamp the source of light is in reality a luminous disc partly eclipsed by the negative carbon. The central zone of the mirror only receives rays from a portion of the crater, which portion viewed from a point in such zone presents the form of a crescent. In Fig. 3 it will be seen that the point A of the mirror, for purposes of parallel projection, must have its focus situated, not at F, but rather at a point, such as *f*, further off. This condition cannot be fulfilled with a parabolic mirror. The Mangin mirror can, on the other hand, be calculated so that its central portion may have a focal length longer than those of the marginal zones, and the conclusion is that the Mangin mirror utilises the rays emitted by a horizontal lamp more completely than does a parabolic mirror.

3. *Quantity of Light Utilised.*—On account of its great concavity, the Mangin mirror collects a great number of the rays emitted by the source. Thus, Fig. 4 shows that the angles of

Digitized by Google

collection for a 60cm. by 31cm. Mangin mirror is 113deg., whereas that for a parabolic mirror of the same diameter and same focal length is only 101° 40′. The divergence of a beam depends solely upon the focal length, so that these two mirrors having the same focal length will produce, with similar diameters of crater, the same size of illuminated field. The Mangin mirror will, however, in such cases give a greater intensity of illumination of field owing to the greater quantity of light collected by it as compared with the parabolic mirror. In order that the parabolic mirror may collect the same quantity of light as the Mangin, it would be necessary to reduce its focal length to 27·9 c.m. (*vide* Fig. 5). But then the area of the illuminated field would be approximately increased in the proportion of the square of 279 to the square of 318—that is, by nearly 30 per cent.—and the intensity of illumination would be reduced proportionately. We may conclude, therefore, that given surfaces at given distances are illuminated more intensely by the use of the Mangin mirror than by the use of the parabolic mirror of similar dimensions.

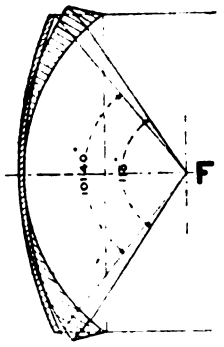

FIG. 4.

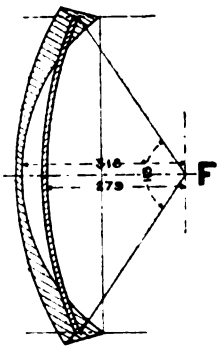

FIG. 5.

4. *Size of the Illuminated Field.*—Partisans of the parabolic mirror hold that their system is the only one which will give an extensive field, because such system lends itself to the employment of short focal lengths. This assertion is not exact, for the reduction of the focal length of the Mangin mirror is only limited by the necessity of preserving a distance between the focus and the glass sufficient to prevent the over-heating of the latter. Experience shows that for the above reason the focal length should not be shorter than one-half the diameter of the mirror. The 60c.m. Mangin mirror already nearly fulfils this condition as its focal length is 31·8c.m., and this result has been obtained, as has been shown, without any sacrifice of aplanatic qualities. There would be no difficulty in constructing a Mangin mirror of 90c.m. diameter with a focal length of 45c.m. More even could be done in this direction, but when the troubles due to over-heating are considered, it is found that nothing is gained by carrying the reduction of focal length beyond the limit above indicated. We may therefore conclude that the Mangin mirror allows of the production of an illuminated field which is quite as large as that produced by a parabolic mirror.

5. *Homogeneousness of Beam.*—Homogeneousness of beam, and consequent uniformity of illumination, are of the greatest importance for purposes of vision. An object is most easily distinguished when it is situated on the edge of the beam, the contrast between obscurity and the part brightly illuminated producing greater visibility. It is important, therefore, that the edges of the beam should be as luminous as the centre. To arrive at such a result it is necessary for all the zones of the mirror to give the same divergence. On referring to Fig. 4, it will be seen that the marginal zones of the parabolic mirror are further from the focus than are the central zones. The angles subtended by the source of luminosity at points on the margin of the mirror are thus smaller than those at points in the central portions, and the divergence of rays reflected from the marginal zones becomes less than that of rays reflected from the central zones. The rays, therefore, sent out from the marginal zones remain in the central portion of the beam, whilst the rays composing the edges of the beam are furnished entirely from the central zones of the mirror. In the Mangin mirror, however, in consequence of its greater concavity, the focal distances of the various zones do not vary to the same extent, so that it follows that the beam issuing from a Mangin mirror must be more homogeneous than that issuing from a parabolic mirror.

6. *Concentration of the Beam.*—One peculiar property of the Mangin mirror is that it allows of the concentration of the beam upon the illuminated object, and in consequence it affords the power of intensifying the illumination of such object. Again, by reducing the distance between the mirror and the luminous source, the beam can be dispersed without losing its homogeneousness. With a parabolic mirror, on the other hand, the source of luminosity must be rigorously kept in focus, otherwise the distribution of light in the field will be seriously affected, and the intensity of illumination in part reduced accordingly to a dangerous extent.

7. *Coloration of the Beam.*—It has been urged as an argument against the use of the Mangin mirror that the edge of its beam is coloured, and that the visibility of objects illuminated is therefore reduced. This statement is not borne out by experience. Whatever coloration exists at short range disappears totally when the object illuminated exceeds 300 or 400 metres in distance. This is easily explained when one considers that the rays emitted from various points of the mirror cross one another and get mixed up, so to speak, to such an extent that the light which has been decomposed in leaving the projector is subsequently recomposed, or combined, and it is an established fact that the chromatic aberration of the Mangin mirror is practically nil.

8. *Effect of Thickness.*—The loss of light due to the thickness of the edge of the Mangin mirror has often been urged in argument against its use by those who uphold the use of the parabolic mirror. Theoretically there is truth in the argument, but practically the loss of light caused by the thickness of the glass is absolutely negligible. Carefully conducted experiments have shown that the loss of light is only ·3 per cent. per centimetre of thickness. A 60cm. mirror has a thickness at its edge of 50mm., and consequently the loss of light passing twice through the extreme marginal zone only amounts to 3 per cent., and this percentage of loss is of course gradually decreasing towards the centre, where the glass is only 5mm. in thickness. It may be taken, then, that the loss of light by absorption due to the marginal thickness of the Mangin mirror is so small, that it may for purposes of comparison be neglected.

9. *Weight and Strength.*—The parabolic mirror is undoubtedly light as compared with the Mangin mirror. The advantage of lightness has, however, been much exaggerated. A Mangin mirror of 60cm. weighs 20 kilos, a parabolic mirror of the same diameter weighs 6 kilos. The difference of 14 kilos is the maximum that should exist between two projectors built respectively on the two systems. The parabolic mirror from its very lightness, and consequent flexibility, requires a massive mounting, and, if necessary, the extra weight of the Mangin mirror, which in itself possesses considerable rigidity, could be compensated for by a reduction in the weight of its mounting. If Mangin projectors are generally heavier than parabolic projectors, it is therefore really because the makers of the former type consider that this class of apparatus, generally speaking, requires to be of especially massive construction, in order that it may not suffer when placed in unskilled hands; and it may be stated generally, that the extra weight of Mangin mirrors, when compared with parabolic mirrors, is compensated for by superior strength.

10. *Uniformity of Manufacture.*—In the construction of Mangin mirrors, the principle on which they are ground allows of the possibility of designed dimensions being rigorously adhered to. This is not possible with parabolic mirrors. The grinding of the Mangin mirror is performed by working the glass on spherical metallic formers, to which are communicated movements of rotation and of translation. Whatever be the initial positions of these tools, the resultant curvature comes out correctly, and is independent of exactness of form of the tools, of the motion imparted, of the skill of the workmen, of accident to the machines, and of the wear of the working parts. The spherical working eliminates the inequalities of the tool, and also those of the glass, and the more prolonged the operation the more perfect is the curvature obtained. This property of the system is valuable. It supplies practical means of constructing reflectors of uniform curvature and having identical properties. Thus, in a lot of 20 Mangin mirrors, no single mirror would be found the optical constants of which would differ from their calculated values by more than from ·1 to ·2 per cent. Parabolic mirrors are, on the contrary, extremely difficult to construct accurately. In practice an approximation has to suffice. The mechanism employed to cut the glass to a parabolic curve is complicated and delicate, and must be set with great exactness. Skill on the part of the workman and continuous supervision of his work are necessary in order to prevent an undue departure from the theoretical section. The unavoidable play between different pieces of the machine, and the wearing of the rubbing portions of the mechanism, seriously interfere with the uniformity of a batch of reflectors turned out from the same machine.

As it is difficult to determine the definite defects of a finished glass reflector, and as it is impossible to test it during the process of cutting, the maker is often not in a position to remedy defects of form due to workmanship. Not knowing the defect, he is unable to arrive at the cause. When the machines are new their performance is fairly satisfactory, but as manufacture proceeds the results show greater and greater defects. The effect of imperfect curvature is to prevent the various zones of the mirror from having same focal lengths, and it is not uncommon to find a difference between the focal lengths of the marginal and central zones amounting to as much as 15mm. to 20mm. In such a case the luminous rays are unevenly dispersed in space over an angle considerably greater than that representing the theoretical divergence of the mirror. The illumination of the objective being inversely proportional to

Digitized by Google

the square of the angle of divergence, the useful effect of such a projecter will be reduced very seriously. Taking a particular instance, let us suppose a 60cm. parabolic mirror, which should have an angle of divergence of but 2° 20′ to have (as is frequently the case) an angle of divergence of 3° 0′. The illumination of the field will then only have a mean intensity of 49/81, or five-eighths of what it should be had the mirror been accurately constructed.

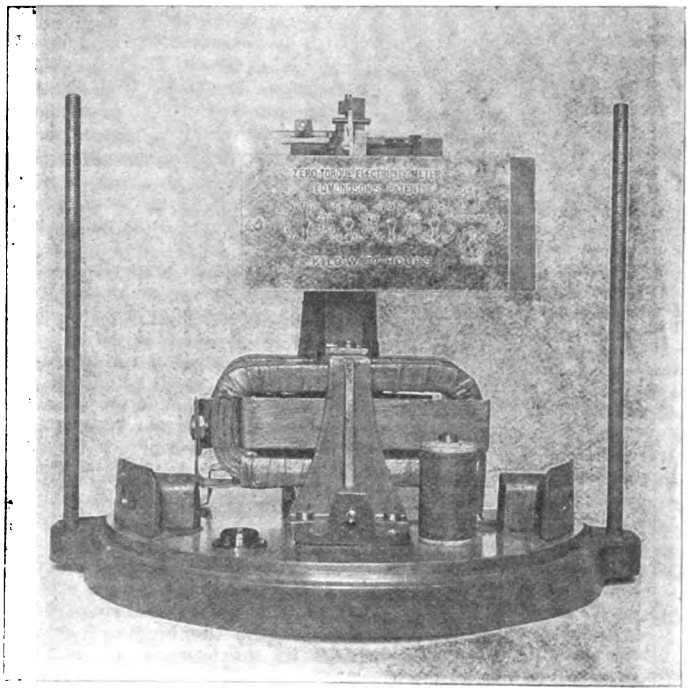
In proof of the above, recent experiments made by the Russian artillery staff may be quoted.* In these experiments the images of rectilinear grids or network reflected by Mangin and Schuckert mirrors were photographed, and this method of investigation showed in a most striking manner, not only the defects of the parabolic mirrors, but also their want of uniformity of manufacture.

It may be fairly concluded that Mangin mirrors can without difficulty be made of uniform quality, but that parabolic mirrors, on the other hand, vary much in their quality, which depends upon the condition of the machines and upon the skill of the workmen. Had the invention of the Mangin mirror been made subsequently to the introduction of the parabolic mirror, it is thought that such invention would have been hailed as an important step in the progress of the development of projectors.

THE ZERO-TORQUE ELECTRICITY METER.†

BY JOSEPH EDMONDSON.

The zero-torque electricity meter, as its name implies, consists of a zero-reading dynamometer, combined with mechanism



Zero-Torque Meter—View of Internal Mechanism.

for measuring and integrating, at short intervals, the torque exerted on the moving coil by the current going into consumption.

The Siemens dynamometer is familiar to electricians as an instrument of the utmost simplicity and accuracy, giving, when coupled as a wattmeter, absolutely proportional readings throughout any range. Its obvious advantages in these respects point to it—in a form somewhat modified, but retaining all its essential features—as a pre-eminently suitable basis for a supply meter, and numerous attempts have been made to adapt it to this purpose. Heretofore, however, the action of all such instruments has depended on complicated arrangements for making and breaking contact. In the zero-torque meter these are entirely avoided. The moving coil of the dynamometer is in a closed circuit which is never broken. It carries a small steel stop which controls the registering without in the slightest degree interfering with the free and frictionless action of the instrument.

The motion of the moving coil being limited to an arc of less than 1deg., permits the use of a durable steel wire suspension instead of the delicate suspension of the ordinary dynamometer. A torque of about 90deg. is given to the usual spiral spring every two minutes by a reciprocating quadrant, or "mangle wheel," driven by a vibrating motor consisting of a magnet and its armature. This motor is controlled by a small gravity-driven pendulum, starting automatically and having a sparkless contact (Oulton and Edmondson's patent).

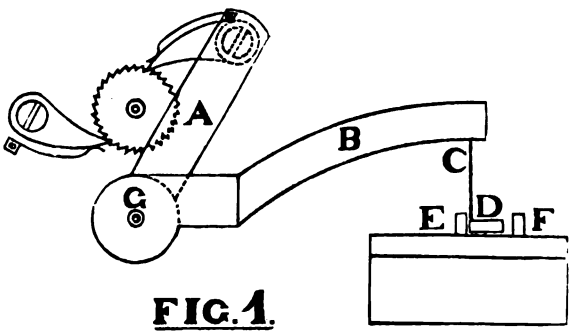


FIG. 1.

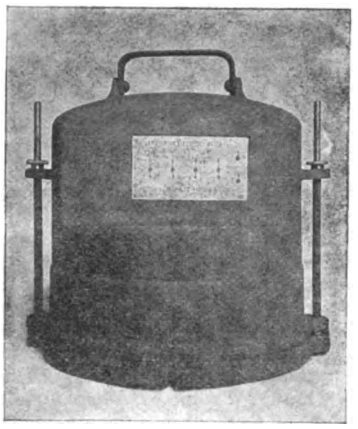
The action of the instrument is illustrated by Figs. 1 and 2, in which A is an arm pivoted at G, carrying a click working into a ratchet wheel, and driving the registering train. It receives a reciprocating motion from the vibrating motor. Fixed on its arbor is the arm B carrying the steel pin C. The flat steel stop D, on an arm projecting from the moving coil of the dynamometer, is free to move between the stops E and F. When the current is nil the stop D remains against the stop E, as in Fig. 1. In this position the pin C comes down upon it at each vibration, and the arm A is thus prevented from vibrating far enough to take a tooth of the ratchet wheel. The registering is therefore nil. But when the force of the current moves the stop D to the right, and it assumes the position shown in Fig. 2, the pin C can descend into the space between the stops D and E, the arm A can vibrate to its full extent, and the registering proceeds. This continues until the reciprocating quadrant or



Zero-Torque Meter—External Appearance.

"mangle wheel" in its motion to the left, acting through the spiral spring, exerts on the moving coil of the dynamometer a torque equal to that exerted by the current, brings the stop D back to the position shown in Fig. 1, and stops the registering. This action is repeated with each reciprocation of the "mangle wheel."

As the period during which the registering proceeds is exactly proportional to the torque exerted by the current on the moving coil of the dynamometer, the diagram of registration is a straight line. A 25-ampere meter will register from 1-10th ampere upwards. The total current required for the

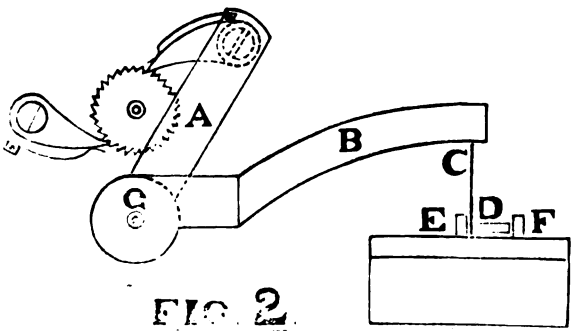


FIG. 2.

shunt circuit and the vibrating motor never exceeds, and is generally less than, 2-100ths of an ampere. The moving coil of the dynamometer, being in the centre of a cylindrical iron case, is shielded from external magnetic influence. The meter is calibrated to read direct in kilowatt-hours with a constant of 1.

ON THE RECENT DEVLOPMENT OF THE SINGLE-ACTING HIGH-SPEED ENGINE FOR CENTRAL-STATION WORK.*

BY MARK ROBINSON, MEMBER.

(Continued from page 533.)

ERRATA.

Page 530, col. 2, line 15 from bottom: after "in a double-acting engine" add "except the special packing rings, and those only by completely duplicating them upon each piston."

Page 532, col. 2, line 17 from top: after "to the other" add "except by absolutely duplicating the packing arrangements of each piston."

It is obvious that with modern pressures it would be better to compound the engine—to give it one smaller cylinder and one larger, and add to the diagram the piece shown in dotted lines in Fig. 7, while making the division of temperatures more equal, as is also shown in Fig. 7. But whether the engine be simple, compound, or triple expansion, if it is single-acting there will always be one cylinder—viz., the last of the series—to which the Cornish cycle may be applied. Mr. Willans applied it in his engine when circumstances were favourable, and he called it the "transfer plan." The steam, when it exhausts through the central valve from the upper to the lower part of the low-pressure cylinder, does not pass away at once to the condenser: it remains in the cylinder (offering no material opposition to the movement of the piston, because the two sides of the piston are in free communication), and passes to the condenser during the succeeding down stroke. It adds to the engine another stage of temperature division, though not of large range, and so lessens the range in each of the others.

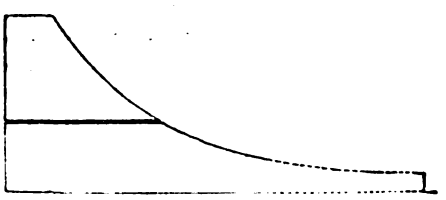

FIG. 7.

Simple as it sounds, the "transfer" adds several parts to the engine. The cylinders are lifted a good deal, as a "transfer-chamber" is required below the low-pressure cylinder; the trunks or hollow piston-rods are lengthened; and an extra valve and an extra gland are required in each line, and, of course, involve extra friction. Thus it is only under particular conditions of pressure, etc., that it is worth while to use the "transfer"; it is often better to add another complete stage of expansion rather than the transfer. It is, nevertheless, useful in cases where, for some extraneous reason, such as very great fluctuation of load, it is convenient to cut down the number of stages of expansion, as in an engine for electrical railway work. In such an engine the average load is usually but a small proportion of the extreme load, and the total cylinder volume should be so chosen as to give the best ratio of expansion, and therefore the most economical consumption, at the average load. It might then be impossible, without much complication, to obtain the extreme load at all, if the first cylinder were relatively so small as that of a triple-expansion engine must be, and if the cut-off in it, for normal load, were as late as in a triple-expansion engine it ought to be; it is better, therefore, to use a compound engine, gaining the needful expansion by cutting off early for average loads, and of course cutting off late (economically, too late) for extreme loads. Economy suffers from this, but it can be partly restored by adding another temperature-division stage in the shape of the "transfer." Where the steam pressure exceeds 160lb. it is also worth while to add the "transfer" to a triple-expansion engine; it takes it half-way towards quadruple expansion, the latter not being, in a Willans engine, worth the complication it introduces, until the pressure is well over 200lb.

It will be noticed that the last statement is qualified by the words "in a Willans engine," and by this is meant that the Willans engine, even if the "transfer" is not used, has always one definite source of superiority over other engines working with the same number of expansion stages—*i.e.*, compound or triple—namely, in respect of the smallness of its temperature range in each cylinder. The explanation is that, in all the expansion stages except the last one—*i.e.*, in the high-pressure and intermediate stages—the Willans engine works necessarily upon the Cornish cycle; the "transfer" is applied in those stages as a matter of course. In double-acting engines, the exhaust steam passes direct from one cylinder to the next, placing the two in communication through the receiver, and therefore exposing the first of the two to the same temperature as the second; in the Willans engine each cylinder exhausts successively in the Cornish manner, and the power developed in each is represented, as in the Cornish engine, by two diagrams—that from the cylinder proper and that from the "receiver." The effect is that the temperatures of the high-pressure and intermediate cylinder, for instance, do not overlap, as in other engines they do, and the range in each is consequently smaller. It is perhaps the most distinctive feature in the Willans engine; it is highly advantageous to it; and it is of interest as a meeting-point between the very oldest and the very newest, and as bringing together in significant association the names of James Watt and Peter Willans—an association which to the author has always appeared natural, and which he believes will at no distant time be so recognised by all.

Brake Efficiency.—Having fully dealt with the three special points of advantage peculiar to single-acting engines, enumerated in paragraph 11, it will be of interest to investigate the effect of the single-acting principle upon brake efficiency. Generally, a single-acting engine has higher brake efficiency when fully loaded than a double-acting engine. The perfect lubrication of all brasses and bearings in the splash-chamber of a single-acting engine naturally reduces that part of the friction to a very small figure, and the total absence of back-lash or "lost motion" is believed to tell as strongly in the same direction. On the other hand, single-acting engines, or at least the Willans engines, though they have no stuffing-boxes, have unusually numerous piston and other rings, mainly owing to the practice of putting a complete tandem engine over each crank—or three cylinders over each crank, if triple expansion. Nine complete cylinders,* as fitted in three-crank triple-expansion engines, with their valves and glands, imply a large number of rings, and even in a two-crank compound engine there are a good many. The special design of the rings, which has been fully described in paragraph 12, coupled with accuracy in manufacture, bring the total friction, however, to a reasonably small amount. After some months' running it is not uncommon to find the brake efficiency of compound engines as high as 92 per cent., but on trial at the works, when the rings are new and not yet brought up to a good face, it is rare to get more than 90 per cent., and 89 per cent. would not be thought unsatisfactory. In a triple-expansion engine 87 or 88 per cent. is a good result when new. Though experiments are sadly wanting, it is believed that these figures are much about the same as those for good double-acting engines, in which there is less ring friction but more bearing friction.

Mr. Willans's diagram of total water consumption, shown in the discussion upon Mr. Crompton's paper upon "The Cost of Electrical Energy,"† has familiarised everyone with the rather puzzling fact, that in almost all trials at Thames Ditton, with good dynamos, the lines representing total water per electrical horse-power and per indicated horse-power remain nearly parallel for all loads; in other words, the combined engine and dynamo losses, and *a fortiori* the engine losses alone, are as great at light as at heavy loads. Makers of some double-acting engines are believed to have obtained results differing from this, and showing a considerably reduced engine friction at light loads. Probably both are right. In both types the ring-friction is constant. In the single-acting engine the bearing friction is also practically constant, because its maximum is so small that variation in it is unimportant. In the double-acting engine the bearing friction‡ at full load is relatively great, and as it falls off at light load, it considerably reduces the total friction. If the single-acting engine beats the other handsomely at full load (as it often does), the effect may only be to bring them together at light load; but where the double-acting engine is exceptionally free from friction, and makes a more even fight with the single-acting engine at full load, it may have a distinctly higher efficiency at light load.

The value of improved efficiency at light loads is not large, for the unwisdom of running an engine at light load for any permanent use is too great to be redeemed by any probable saving in engine friction. If light loads have to be faced, there should be a smaller engine to undertake them, small enough to make a full load of them, or nearly so.

* Paper read before the Institution of Electrical Engineers, May 9.

* Twelve complete cylinders, has been unkindly said, reckoning the guide or cushion cylinders. But the reproach is not quite just, since the guide cylinders, with their ring-less pistons, merely represent the guides and cross-heads of other engines, and are quite as simple.

† *Proceedings* of the Institution of Civil Engineers, vol. cvi., 1890-1.

‡ In "bearing friction" is here included that which is assumed to be due to back-lash—*i.e.*, to the incipient "knock" necessarily present where there is alternation of stress. It is to be remarked that the heat generated by knock upon brasses is wholly lost; but heat generated by piston-ring friction is partly utilised in heating the cylinder walls and pistons, and so reducing condensation. In the single-acting engine, therefore, a greater proportion of the friction loss is returned in reduced consumption of steam, than in a double-acting engine having the same total friction.

Digitized by Google

The possible higher efficiency of double-acting engines at light loads is well illustrated in a paper read by Mr. Alexander Siemens before the North of England Institute of Mining and Mechanical Engineers in December last. It describes fully a series of trials in the central power station belonging to his works at Woolwich between a Willans engine (three-crank) of 300 i.h.p. and a Belliss double-acting engine (two-crank) of the same power, and running at the same speed, 350 revolutions per minute. The dynamos were apparently identical, and all the conditions appear to have been as favourable to a fair test as they can ever be in a commercial engine-room. There are anomalies in the very interesting figures given, but there is no reason to mistrust their general tendency. At 270 i.h.p., the highest power used, the combined efficiency of the Siemens-Willans plant was 86 per cent. against 85·1 per cent. in the Siemens-Belliss, but at light loads the advantage of the latter was considerable, as appear below :

	Electrical horse-power.	Indicated horse-power.	Horse-power lost in engine and dynamo combined.
Willans set	231·2	268·9	37 7
Belliss set	230·4	271 6	41 2
Willans set	114·6	149 2	34 6
Belliss set	120·3	144 7	24 4
Willans set	60·9	95·7	34 8
Belliss set	60 5	79·4	18 9

There is much in these figures which is with difficulty reconciled with any probable assumption as to the respective engine and dynamo losses ; but there is no doubt that in the double-acting (Belliss) engine the friction became very small at light loads. As it had but two cylinders and ran at high speed, there could be but little ring friction at any load, and it looks as though at light loads the bearing friction almost disappeared ; probably the crank-pins and shaft "floated" in their brasses, permanently separated from them by the oil which was forced in under pressure. It is, however, instructive to notice that with increasing load, and notwithstanding its great advantage in regard to ring friction (it probably had little more than one-third as much ring friction as the other engine), the total friction of the double-acting engine rapidly overtook that of its rival, and it is evident that had trial been made at the much higher mean pressures frequently used in non-condensing stations, the advantage of the single-acting engine would have been very marked indeed. It seems possible that, although the exceedingly elegant system of lubrication adopted in this double-acting engine is effective when the pressure per square inch on the brasses is light, yet the alternating pressures of the parts begin to produce their natural effect at heavier loads. In the single-acting engine security from wear and knock is obtained by ensuring that the revolving journal shall remain always in steady contact with the same brass : in the remarkable double-acting engine described, an even more perfect result is perhaps obtained at light loads (which, however, are not of the highest importance) by providing that the revolving journal shall touch neither brass ; but it remains to be seen whether in continuous running at heavy loads, the brasses will not relapse more or less into the condition of those of an ordinary double-acting engine. It is at least plain from the Woolwich figures that even at 270 i.h.p. the bearing friction (as distinguished from ring friction) of the double-acting engine is enormously greater than that of the single-acting engine, and the law of its increase might well repay investigation. Provisionally, it is difficult to resist the conclusion that bearing friction—*i.e.*, the actual rubbing of the journal upon the brass—is of small importance in engines in which the lubrication is very perfect, as in the Willans engine through its oil-bath, or in the Belliss engine through the forcing in of oil under pressure*; and that, in double-acting engine at heavy loads, the most important element of friction loss—or it may be safer to say of power loss—is to be traced to the knock of the journal as it changes over from one brass to the other—a source of loss which the single-acting (constant-thrust) engine avoids altogether. Whatever be the ultimate verdict, no one can withhold admiration for the ingenuity and indeed beauty of the device by which it is sought to overcome so great a difficulty, and it is most satisfactory that in such an interesting and important trial the double-acting principle has been, and continues to be, represented by so perfect an example.

Passing to the results of experience with single-acting engines in the last few years, it may be well to deal separately with (*a*) steam consumption, (*b*) durability, (*c*) lubrication, (*d*) vibration.

Steam Consumption (*a*).—The consumption of the best-known type of single-acting engine, under all loads, is known not only from the almost historic series of tests conducted by Mr. Willans, but from numerous other trials carried out at Thames Ditton. It is, however, a frequent objection that the small consumption of steam per kilowatt upon test bears little relation to the actual consumption of coal per kilowatt sold ; and doubt is often expressed whether the engine consumption does not increase with use and wear, or whether test figures are not vitiated later by variation in load. It is satisfactory to be able to answer this question. At the stations of the Westminster Company, Dr. Kennedy, F.R.S., has for a long time had accurate records kept of the quantity of water supplied (by meter), as well as of the load upon each engine separately. The "Thames Ditton" consumption for every engine at all loads is, of course, known, and has been compared with the actual consumption, and after allowance for steam known to be condensed in pipes and used in pumps, etc. (mostly ascertained by experiment), the result is an almost exact balance. Probably there really are unrecorded losses for which a margin would have to be provided, if it were not that the engines work at a little less than the calculated consumption, since the latter is, of course, based upon the trials of the same engines at the makers' works when new and stiff. Some of the engines at the stations had been at work for over five years, and few for less than two years, so all had had time to bring the rings and other wearing surfaces into the best condition for economy.

At the meeting of the Institution of Mechanical Engineers on April 24, 1895, the above facts were well shown in a diagram exhibited by Mr. G. M. Clark. Two cases were taken from the same station : one for a heavy winter load, covering 24 hours ; the other for a week's load in summer. The leading particulars were :

	Winter load (24 hours). 3,350		Summer load (one week). 9,000	
Output in kilowatt-hours				
Measured total water consumption per kilowatt-hour ... lbs	—	46	—	48
Measured steam consumption of engines at Ditton trials (full load, non-condensing), per kilowatt-hour ... lbs.	32·5		32·5	
Calculated addition to steam consumption (non-condensing) on account of low load-factor ... lbs	8 0		9 5	
Total calculated engine consumption per kilowatt hour ... lbs	40·5		42·0	
Measured consumption of steam in pumps per kilowatt-hour ... lbs.	1 5		1·5	
	42 0		43 5	
Balance attributable to condensation in pipes, leaks, etc., ascertained by previous trials to vary from 7 per cent. to 11 per cent. of total consumption ... lbs.	4 0		4·5	
		46		48

These figures may be commended to those gentlemen of the technical Press who tell us that theory never helps anyone ; that no engine builder knows within pounds what weight of steam his engine is likely to use in practice ; and who apparently reckon no man practical if he knows the reason for what he does or is able to foresee the result.

It is important to enquire whether the economy of the single-acting engine may be expected to make any notable advance beyond the results hitherto obtained. The answer is yes, but here (speaking of the Willans engine only) it is necessary to distinguish between actual engines as fitted in the majority of stations and the new type only recently made. Owing to various circumstances, the demand for the central-valve engine came at first chiefly from users who desired to work without condensation, and its fame was first established by Mr. Willans's paper upon non-condensing trials, in which he showed figures not before supposed to be possible for non-condensing engines (such as a consumption of 18·45lb. of steam per indicated horse-power with 170lb. pressure, triple-expansion ; and 19·45lb. with 150lb. compound). But Mr. Willans's paper, and his practice at that time, did more than this—they pricked the bubble of over-expansion. Here was a little non-condensing engine which, with five or six expansions, used scarcely more steam per indicated horse-power, and obviously less per brake horse-power, than many large (not to say overgrown) condensing engines which expanded their steam twenty-fold or even thirty-fold. But the ease of the triumph tended to mislead, and the same ratio of expansion, without the moderate increase which was really desirable, was provisionally attempted in condensing work. A few months before his lamented death, Mr. Willans carried out a complete series of condensing trials, which proved that, while nothing could justify the excessive expansion formerly allowed by some makers, the Willans engine, as then made, erred, though less seriously, in the other direction. A new series of engines has since been designed in which the

* If the mere rubbing of the journal and brass together at heavy loads were seriously important in a thoroughly lubricated engine, the Willans engine would show increasing friction at heavy loads. It does not do so, and even the moderate increase (in engine and dynamo together) shown in the figures extracted from Mr. Siemens's paper is exceptional. The increase in the Belliss engine, therefore, can hardly be due to this cause, and other reasons must be found for the increase which undoubtedly occurred.

Digitized by Google

necessary greater expansion is provided for, the ratio of the cylinders being altered at the same time; and in which a number of minor improvements, tending to the suppression of petty losses, considerable in the aggregate (but much less important in a non-condensing than in a condensing engine), have been introduced. From these engines, which have but just commenced to find their way into station work, great economy may be expected. The earliest was a triple-expansion mill engine indicating up to about 500 h.p., driving the flax mill of Messrs. Gunning and Campbell, Limited, at Belfast, at 300 revolutions per minute, and in some very complete trials carried out last year by their consulting engineer, Mr. A. Basil Wilson, M.I.M.E., after the engine had been at work for about six months, a consumption of 12·48lb. of steam per indicated horse-power was recorded. This places the single-acting engine, to say the least, in the very foremost rank of economical motors. Evidently electrical engineers need not fear that they must abandon economy if they do not "stick to the builders of mill engines and marine engines." In fact, it seems not impossible that, while advocates of the "mill engine" are pleading for central-station work, they may find themselves the victims of a flank movement, and learn too late that their special patrons, the mill engineers and owners, are becoming as open-minded as the electricians, even to using "electric light engines" for driving their mills.

It may be remembered that in Mr. Willans's paper on non-condensing trials figures were given for one condensing trial at 170lb. pressure, carried out with the same triple-expansion engine as had been used for the non-condensing trials; the consumption was 15·1lb. per indicated horse-power per hour. With the old engine that result has not been much improved upon, so it may be reckoned that the new series are about 15 per cent. better in steam economy than the old, when condensing. For non-condensing work, and for condensing work in special cases, the old series engines are still the most suitable, while from the smaller cylinder capacity they are less costly to make. The engine at Messrs. Siemens's works at Woolwich, the trial of which against a Belliss engine has been before referred to, was of the old pattern, compound, but fitted with the "transfer" arrangement; in other respects it was of the proportions now recognised as suitable for non-condensing only. The steam consumption at full load is given by Mr. Siemens, in his paper before quoted, as 19·5lb. per indicated horse-power, against 22·4lb. in the double-acting engine. It is understood that these figures of steam consumption are based upon the total water actually supplied to the boilers, with a deduction only for steam used in pumps; they presumably include pipe condensation and leakages of all kinds, and it is probably from such causes, rarely absent from a commercial engine-room, that the water used comes out some 2lb. per indicated horse-power per hour above that due to the proper steam consumption of the old type Willans engine at the load and pressure stated. (The vacuum is not given.) Of course the Belliss engine was similarly affected.

Reference has been made to the numerous cylinders of the Willans engine, due to the practice of erecting a complete engine over each crank. By adding to the number of pistons and valves the ring friction is, of course, increased, and it is equally certain that condensation is increased, and economy affected unfavourably, owing to the larger aggregate surfaces of the two or three small cylinders which take the place of what might otherwise be a single large one. On the whole, however, the advantages appear to outweigh the drawbacks. The first and most obvious is even turning moment. Whatever the change in load, in pressure, or in cut-off, it is at least certain that the cranks will be driven equally, and this is an advantage not to be lightly surrendered for only a small gain in economy. But the same tandem arrangement of cylinders is also the condition of the complete application of the Cornish cycle to all the cylinders except the low-pressure one: the perfect separation between the temperature ranges of the successive cylinders is impaired if their strokes do not succeed each other at intervals of exactly a revolution, as they now do in the tandem pattern; even economically, therefore, there is something to be said in favour of the many small cylinders. Turning to other considerations, it may be thought at first that the large number of small cylinders and multiplication of parts must lead to increased weight and cost, as well as to difficulty in dismantling and overhauling. As to weight, it is almost certain that it is not increased. Cylinders weigh roughly in proportion to volume, but the weight of a piston tends to increase faster than the area; three pistons, each of one square foot area, will weigh less than one of three square feet area. To cylinder covers the same consideration applies. Piston-rods, connecting-rods, and crank-shaft should be unaltered. There may be some saving in machine work, but small pieces are, after all, easier to machine than large ones, and pieces which are made in batches of, say, 36, are more economically manufactured than larger pieces made in batches of 12 only. Then the identity of the several lines of parts and their interchangeableness are often helps to the user (especially in case of repairs), while the lightness of the individual pieces and the regular and simple routine in removing them make dismantling easy. A Willans cotton-mill engine of 650 i.h.p. pulled up one day after the dinner hour, with brasses cut to pieces and crankshaft badly scored. (Of the cause, it need only be said that emery powder was found in the bearings and in the crank-chamber.) Next morning, after breakfast, it started again with new brasses and crankshaft in good order. By good luck another engine of the same size was being erected in the same town, and its brasses were at once appropriated for the disabled engine, and every necessary repair thoroughly carried out during the night. It is true that in this case the cylinders did not require to be lifted, but there have been as rapid repairs to cylinders, pistons, etc., where internal damage has been done by water. Some years ago three three-crank triple-expansion engines of 300 i.h.p., to save the reproach that they had nine cylinders each, were designed with only six cylinders—viz., one high-pressure, two intermediate, and three low-pressure. It is remarkable that not only have all later engines of the same type been fitted with the orthodox nine cylinders, but the original engines in question are now being altered to the standard pattern. With larger sizes may, possibly, come different views, but as regards the present standard patterns for 700 i.h.p. or 800 i.h.p., experience gives little support to objections against the number of cylinders.

(To be continued.)

ALTERNATING AND INTERRUPTED ELECTRIC CURRENTS.*

BY PROF. GEORGE FORBES, M.A., F.R.S., M.I.C.E.

LECTURE II.

(Continued from page 542.)

Now, these different phenomena of induction, pleasing as they are, and useful as they are to the electrical engineer, are matters that require considerable caution in their handling. There are some troubles which would arise if sufficient attention were not paid to them, and I am going to deal—it may seem at an unnecessary length—with some of the analogies to show you what happens when we suddenly break a circuit containing much self-induction. Before doing that, I wish to show you a model, which I am enabled to do by the kindness of Prof. J. J. Thomson, which was introduced by Clerk Maxwell to illustrate this phenomenon that I have been describing to you — the phenomenon of induced currents in a secondary wire or coil. It is an instructive experiment to look at, and it is an interesting one, because it shows how thoroughly Clerk Maxwell's ideas were connected with mechanical phenomena when he was working out his electrical theories.

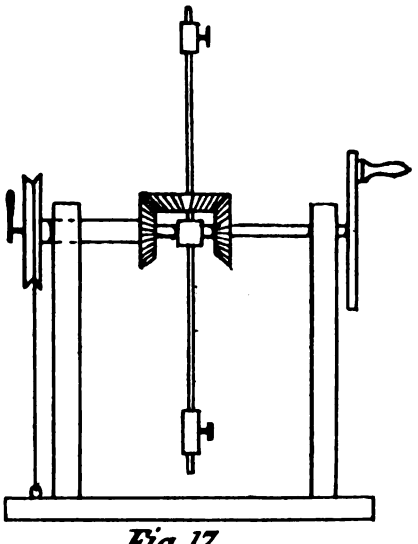

Fig. 17

Here you will notice that I have two wheels (Fig. 17)—one which I am turning, and a second one which is not turning at all. The one which I am turning at this moment represents the primary circuit, and the one which you see is not turning represents the secondary circuit. These wheels are connected, not by a rigid axis, but by means of three bevelled wheels in the centre—one keyed on each of the two horizontal shafts, and the third running loosely on a shaft, at right angles to the others, forming one of four cross-arms, having heavy weights at their extremities, and therefore possessing considerable momentum, and so resisting any tendency to set them in motion round the horizontal shaft of the hand-wheel, to a sleeve running on which they are attached. The consequence is that if I suddenly try to turn this handle round, the

* Lecture delivered before the Royal Institution.

Digitized by Google

momentum of the intermediate gearing will prevent it from turning round at first, and the secondary wheel will turn in the opposite direction to that in which I am turning the first—*i.e.*, if I do it suddenly enough.

But now the intermediate gearing is rotating, and if I suddenly stop the hand-wheel, then the secondary circuit goes on rotating in the same direction in which my hand has been going. This is a very beautiful analogy, but, of course, you must not look upon it as more than a rough sort of analogy. It is not an explanation. If it were an explanation we should have to say, I suppose, that this beautiful gearing and these masses at the end of the cross-arms are parts of the ether. In the true case a motion is given to the ether in the one direction, and the moment the ether has motion it transmits it to the other wire. That it could be an explanation is, of course, quite out of the question. But a mathematician finds a very great help from getting a mechanical thing to illustrate what he wants to arrive at in his theories. I remember that in the celebrated Baltimore lectures which Lord Kelvin gave in 1884, he was trying to work out a theory of an ether and vibrating molecule giving light, and he worked out then and subsequently a view of the ether in which every part of the ether consisted of an assembly of gyrostats. I remember perfectly well his saying: "I do not believe ether is made up of gyrostats, but I am never contented with any theory until I can get a mechanical analogy to satisfy me. After we have the mechanical analogy which satisfies the conditions, we can then work on to get something in the ether which will be analogous to it in the method, though different to it in the mechanical conception."

Now, I want to show you some of the analogies which help to show us the enormous dangers which may be incurred in practice by suddenly breaking our circuits which have very large self-induction. In an alternating-current system, like that which has just been put in at Niagara Falls, the self-induction of the transformers is something very large indeed. And if we were to permit insulated cables to be laid in the earth over considerable distances, the capacity would also be very considerable of these cables. The combined effects of the capacity and of the self-induction would lead to a great deal of trouble, and it has been my effort to reduce the capacity of the cables, and to lay them in such a way that there should be as little capacity as possible, so that that source of trouble should be as much obliterated as could be. Also I introduced the plan of lowering the frequency of the alternations as low as possible, which also assists largely to get over troubles due to capacity. I need not go into that question of the reduction of the frequency at the present moment; but I may say that the further we have gone in the matter the more thankful we are that we realised the necessity in time, and have lowered the frequency to a figure that has never been reached before. It is not only an enormous safeguard to us in countless other ways, but it enables us to use apparatus of a simplicity which would have been impossible with the higher frequencies.

Now, neglecting the question of the capacity, let us deal simply with the question of the self-induction. It is remarkable what great difficulty I have had in getting people to realise the danger that there is in suddenly breaking these circuits containing enormously powerful self-inductions; but I have insisted throughout that it is indispensable to the success of that great work at Niagara that no circuit carrying large currents which are used with these self-inductions shall ever be suddenly broken. I found manufacturers relying simply upon their past experience, and not looking into the new conditions caused by the enormous size of the machinery. I found able manufacturers unable to realise this point. They had noticed, when they broke the circuit of an alternating current with some self-induction, large sparks at the switch. Several had the notion that if they could get rid of these, that was all they had to do. Their desire was to make the break at the switch as sudden as they possibly could, so as to prevent sparks and a train of fire from appearing there. As a matter of fact, by doing so they were endangering the whole system by introducing an enormous E.M.F. of self-induction tending to break down the whole system in one part or the other. I will show you one or two mechanical analogies to illustrate this; and, first, I will adopt the analogy of flowing water which I spoke of last time, which is an extremely useful analogy.

I have here (Fig. 18) a pipe through which I am able to allow water to flow downwards. There is in the middle of the suspended part an opening, which is at present closed. A little brass tube projects from the main tube, and that brass tube is closed simply by means of a membrane of paper, which prevents the water from escaping there. That piece of paper in this analogy represents the insulation on the cable, and what we are going to test just now is the dielectric strength—that is to say, the breaking strain of the paper. If that paper gives out when we suddenly stop the water, then the analogy is, that when we stop the electric current we shall tend to break down the insulation of our cables and any other part of our apparatus. Now I turn on the electric current. By turning the stop-cock I am able to stop it suddenly, and immediately you notice the water escapes through that side tube. If I now open the stop-cock there will naturally be a small leak, through which a very little water trickles; but if I suddenly stop the main flow of water, then the pressure is obviously increased momentarily to a very large extent, producing a spurt of water followed by a steady stream. That is an instructive illustration of the high E.M.F. which is generated when we suddenly break the circuit.

I have been introducing to your notice another analogy—that of rotating bodies—as illustrating a line for the transmission of power or for any other purpose. I will show you now what the dielectric strength of this glass rod is. I have here (Fig. 19) a flywheel, to which I will give a somewhat rapid rotation and then suddenly stop it [*illustrating*], and you see that the dielectric strength of my conductor was not sufficient to stand the strain, and it has broken down. The strain is produced by the momentum of the flywheel—that is to say, by the self-induction of, say, the transformer. I will now put in another rod, and show you how we can prevent these disastrous effects from happening, and that is simply by never breaking the circuit suddenly. By putting in a gradually increasing resistance, the momentum of the flywheel is not able to exert its full impulse instantaneously, and we have a gradual slowing down, and the dielectric is able to stand the strain. To illustrate this, after I have the wheel in rotation, I simply have to grasp it with the fingers and gradually bring it to rest in about a second of time. I have brought it to rest without the slightest undue strain upon the insulation. That means that, with large and powerful plant, in order to prevent the too sudden breaking of the circuit, you ought to have a switch which will enable you to

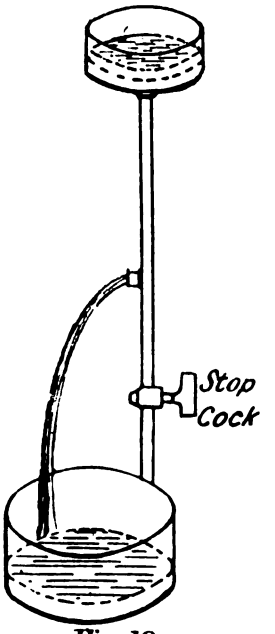

Fig. 18.

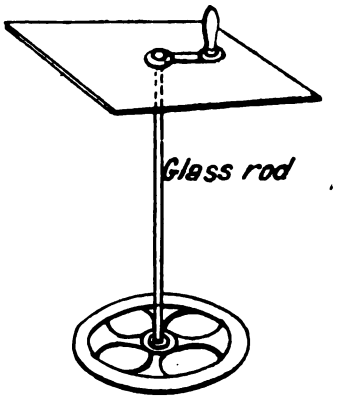

Fig. 19.

gradually insert a resistance before you break the circuit altogether. Then the whole danger to the insulation of the system would be done away with entirely.

Now, I have given you these two analogies because my own experience is that the more analogies we have the greater help it is to us. I know myself that I have gained the greatest assistance from always putting matters into a mechanical form; it assists one to foresee results that may happen, and enables one to apply one's mathematics to it. I do not wish it to be understood that by these analogies one can get rid of mathematics. One can illustrate the qualitative results extremely well, but when we come to the quantitative results mathematics is the true servant to one.

When we are sending an alternating current through a transformer there are two cases that may be considered: one where the power is all being used up, the secondary of the transformer having a full supply of lamps upon it, for instance; and the other where there are no lamps on it, where the secondary is not using up the current at all. In that case there is still a sensible current going through the primary of the transformer, and the question is, What becomes of it? Are we using up a large amount of power in the transformer when the lamps are not on? No, we are not using a large amount; we are using a certain amount. The counter E.M.F. created by the self-induction of the primary of the transformer mitigates this effect when the transformer is doing no work, as then the E.M.F. that is applied to the primary is in opposite phase to the opposing E.M.F. of self-induction. The current, which follows very nearly the impressed E.M.F. when the transformer is doing full work, now, no work being done, lags behind the E.M.F., which still further reduces the power consumed in the transformer on open circuit.

Digitized by Google

Now, what is meant by the lag of the current behind the E.M.F.? I have a model here (Fig. 20) which might have been better designed if I had had more time to do it, but it will illustrate what I want to show you. I have a wheel supported on an axis, and I have two weights, one of which in descending causes the wheel to turn in one direction, the other in the opposite direction. What I wish to show you is that when I stop allowing one of these forces to act, the momentum of the wheel will still carry the wheel round in the same direction in which it was going; although an opposing E.M.F. is acting, the wheel continues to rotate in the same direction. You will see the analogy which I wish to be conveyed to you. Now I apply the E.M.F., or weight, on the right, and it sets the wheel in motion. Now I stop it, and you notice that the other weight still goes up for a sensible time—that is to say, the current lags behind the E.M.F. I might put an alternating E.M.F. on first in one direction and then in the other, but the momentum of the flywheel would always be pulling up during a portion of the time against the weight.

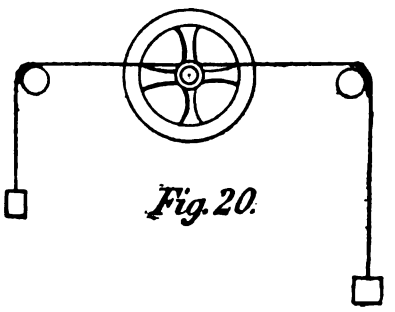

Fig. 20.

Now, I have a very interesting experiment to show you illustrating this lag of the current. It is one which was designed in Prof. Ayrton's laboratory a few years ago by Mr. Smith, and it is a very beautiful experiment. I have here (Fig. 21) two 55-volt lamps connected in series, which will be fed from an alternating source of 100 volts. I shall pass an alternating current through them, and you will see that they light up rather dimly. After that I shall put this high-resistance self-induction coil as a shunt upon one of the lamps, and I shall put on the other lamp a high-resistance non-inductive shunt. Now, the difference between the two conditions of the experiment is this: In the first place, I pass an alternating current through the two lamps in series, and I get a very low illuminating power. I then give a by-path across the one lamp containing self-induction, and a non-inductive by-path across the other, and you will see that the lamps increase in brightness. [*Experiment.*] The reason is that we have to deal with an additional source of E.M.F. besides the main town supply which I am using. This E.M.F. is also tending to set up electric currents, and lags behind the phase of the E.M.F. which is supplied from the mains; consequently we will have these two lamps lighted up by two currents in different phases, and one will attain its maximum when the other is near its minimum. Of course, we do not see this, because the maxima and minima come 150 times a second. So that really by affording by-paths to these two

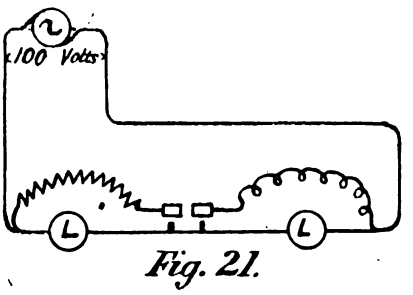

Fig. 21.

lamps we are able to produce a greater illumination than when the whole current is going directly through them. Of course, we are drawing much larger currents from the mains in this case than we were before, but by introducing these coils we are actually able to increase the brightness of the lamps.

Now, the lag of the current behind the E.M.F. is a cause of many curious phenomena, which have been worked out by Prof. Elihu Thomson, of America. Here I have an electromagnet, which I am going to magnetise with an alternating current—it consists of a bundle of iron wires surrounded by a coil, and I will show you that the electromagnet produces a repulsion upon conducting bodies brought into its neighbourhood. Of course, the variations of the electromagnetism due to the alternating current will clearly set up induced currents in a ring or any piece of metal brought near to it. But one would have naturally thought that these currents would be strongest just at the moment when there is no magnetism at all in the core, and that therefore they would act sometimes positively and sometimes negatively, that sometimes there would be repulsion and sometimes attraction, and of equal amounts, and that would be the case if there were no lag in the current. That the reverse is the case, however, is because the current lags behind the E.M.F. induced by the lines of force from the electromagnet. The attraction or repulsion, say, on a ring, at any moment being proportional to the product of the strength of the magnetic field into the strength of the induced current, these former would be of equal amount in an alternation, if there were no self-induction in the ring, and hence no lag, the induced currents being 90deg. later in phase than the magnetic field. But if there is self-induction in the ring, as of necessity there must be, then the induced currents occur more than 90deg. later in phase than the magnetic field, and then the products of the strengths of the two at every moment during an alternation show that there is a

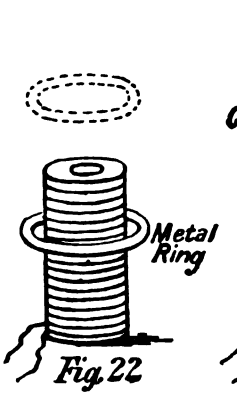

Fig. 22.

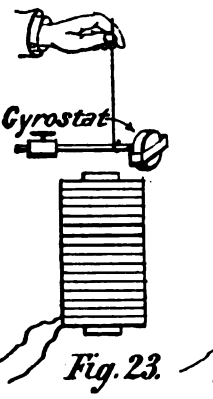

Fig. 23.

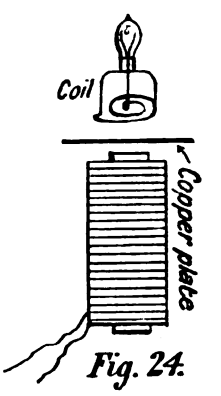

Fig. 24.

marked preponderance of repulsive over attractive impulses; the attraction has become comparatively insignificant. The most striking experiment is with an aluminium ring, because of its good conductivity and lightness, Fig. 22. You see, as soon as I put on the current it throws the ring into the air to a considerable height.

I will now show you the same experiment with a copper ring, which is much heavier, but it is an extremely good conductor. You will see that it will not rise quite so high as the aluminium ring did. [*Experiment.*]

I will now show you that with worse conducting materials the effect does not take place to the same extent. This is a zinc ring, and you will find that it will not rise to so great a height. [*Experiment.*]

I have here a brass ring, which is even a worse conductor still, and it may possibly be able to topple over the edge of the electromagnet, but that is about all. [*Experiment.*]

Here is a ring (Fig. 26) held by two threads to a piece of wood, which I can keep floating above the magnet. [*Experiment.*] The ring, of course, gets intensely hot in a very short space of time, owing to the enormous power that is being expended in it.

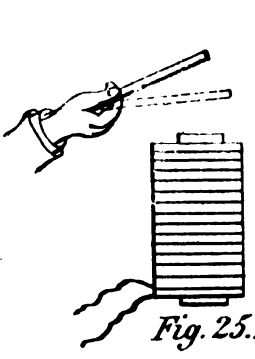

Fig. 25.

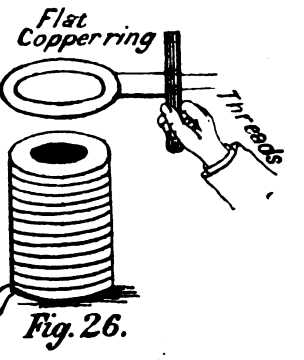

Fig. 26.

There are one or two other experiments I can show you. Here (Fig. 23) we have a gyrostat, which consists of an iron wheel, with a thick copper tyre, which becomes magnetised by the induced currents. The axis is supported on a copper framework that surrounds it, and that causes the lag of the current, which will enable a continuous rotation to be set up in the gyrostat. Here, then, we have an electro-gyrostat driven by this curious force of Prof. Thomson's. He devised a great number of different methods of showing this, from which different results might be obtained. I am able to illuminate this lamp, Fig. 24, but I can screen it off by means of this plate of copper. It is difficult to pass it through because the repulsive force is so great. [*Experiment.*] If that had been a bad conducting material it would not have done it so well, but being a good conductor it screens off the lines of magnetic force and prevents them going through the coil. The lines of magnetic force, instead of going straight up, are bent round.

Digitized by Google

Finally, I will show you the effect of trying to bring a plate of copper upon the pole, Fig. 25. I cannot strike the pole: it always rebounds from it owing to the repulsion caused by the induced currents. [*Experiment.*]

NEWCASTLE-UPON-TYNE CORPORATION.

ELECTRIC LIGHTING PURCHASE.

The following is an abstract of Prof. Kennedy's report to the Special Committee on Electric Lighting, presented by that committee to the members of the Council in anticipation of their own report which will be brought up to an early Council meeting.

The report commences by mentioning the two companies in question—viz., the Newcastle and District Electric Lighting Company (hereafter called the lighting company) and the Newcastle-upon-Tyne Electric Supply Company (hereafter called the supply company), and that the area of supply of each company covers the whole town, though, by a friendly arrangement, the lighting company takes the western, and the supply company the eastern sides of the town. Copies of their annual accounts have been supplied by both companies from 1891 to 1894 inclusive, and every assistance has been given to Prof. Kennedy by the officials of both companies in obtaining the facts and figures necessary for this report.

The supply company has an Act dated June 9, 1893, and its term extends for 31 years from July 3, 1891. The works are situated in Pandon Dene, and their present capacity is 800 e.h.p. They supply energy at 2,000 volts pressure over about 11 miles of roads. The authorised capital is £50 000, of which £34 250 is paid up, and £20,000 of 5 per cent. debentures have been issued, making total paid-up capital of £54,250. The total revenue in 1894 was £7,613: the total expenses (without reserve or depreciation) were £4,856, leaving a gross profit of £2,757. The average price per unit sold in 1894 (including meter rents), was 4·56d., and the average cost 2·91d. The company has paid 4 per cent. since 1891, besides writing off nearly half their preliminary expenses. Taking the capital expenditure per lamp fixed, this company stands lowest on the list of 12 given in Table 5—viz., at £2 21. This may be taken as a test of the wise and proper expenditure of capital. The plant and machinery has been kept, and is now, in thoroughly good order.

The lighting company works under an Act dated July 3 1891, and its powers extend for 31 years from that date. The works are situated in Forth Banks and on Virgin Mary leasehold of 65 years from 1866, terminating in 1931. Their present nominal capacity is 1,300 e.h.p., and they supply energy at a pressure of 1,000 volts over about 9½ miles of roads. The authorised capital is £5,000, of which £39,960 has been issued and paid up; £8.900 of 4½ per cent. debentures have been issued, making total paid-up capital £48,860. The total capital expended has, however, been £52,159, or practically the same as the supply company. The total revenue in 1894 (including meter rents) was £8,203, and the total cost (without reserve or depreciation) £4,413, leaving a gross profit of £3,790. The average price per unit was 4·82d., and the cost 2·59d. It is pointed out that the lighting company includes in its returns, not only units sold to the public, but also the units used in the station itself, while the supply company does not. To make the comparison fair, therefore, the quantities used by the lighting company in their station have been deducted in arriving at the figures given above. The reserve and depreciation fund stand at £2,978, while only £500 of the preliminary expenses still stand in the balance-sheet, the remainder having been paid off. Comparing, again, the capital expended per lamp fixed, the lighting company stands at £2·22, and holds the position next to the supply company on the list of 12 companies given in Table 5, so that in economy of capital expenditure the two Newcastle companies stand in the best position. The works and machinery are in thoroughly good order, and with respect to the mains, Prof. Kennedy remarks that they are in exceptionally good order. He has never found mains in more perfect order than those of this company, so far as he has examined them.

Comparing the two companies, their capital expenditure has been practically the same, and they are selling nearly the same number of units per annum, and have practically the same number of lamps on their mains. The lighting company sells slightly more units per lamp and receives slightly more per unit, but the difference is not large. The supply company has slightly the advantage in coal consumption. Both companies in economy of working, as well as in judicious capital expenditure, stand very high indeed among electric works either in private hands or belonging to corporations over the whole of England, and are doing extremely well in comparison with their contemporaries. Their earning capacities are much the same. The price per unit in Newcastle is very low, varying from 4¼d. to 4⅜d., against Bradford, 5·08d.; Leeds, 5·68d.; Birmingham, 6·45d.; Liverpool, 6·82d.; in London the largest companies only get down to 5¼d., and the average London price is much larger. The low Newcastle price, no doubt, hangs on the very low price of gas. While the companies deserve great credit for reducing cost of manufacture so as to enable them to make a profit even at 4¼d., the margin of profit is not enough to allow the stations to pay on a much larger capital expenditure, while it would be practically out of the question for the Corporation, if they took over the work, to charge more for the product.

The report now comes to the question of the financial justification for the Corporation buying, and here Prof. Kennedy's words are quoted verbatim: "This brings me to the point which is of most importance to the Corporation, the point, namely, how far it would be financially advisable for the city to take over the business of the two companies. There is no doubt, that in a number of cases—I may instance Glasgow and Aberdeen among those which have passed through my own hands, Bradford and Manchester among others—the carrying out of electric lighting by a municipality has been financially successful. I have not the least doubt, also, that if the two Newcastle companies could come into the hands of the Corporation with no greater capital expenditure than has actually been incurred by them, it would be a good thing for the Corporation. But this can hardly be the case, unless I have altogether misunderstood the present position of affairs. There is nothing whatever in the Acts of Parliament, nor in the usage of the Board of Trade, which will compel the companies to sell, unless they actually wish to do so. The purchase of the companies by the Corporation can only, therefore, take place as between a willing seller and a willing buyer. Special provisions for early purchase are made in a considerable number of the provisional orders granted by the Board of Trade. I have been enabled, by the courtesy of Sir Thomas Blomfield, to examine all the orders in which this has been done, and if the committee desire it, I could place in their hands copies of all the clauses affecting the matter. In every case the terms approved by the Board of Trade involve the payment of a considerable, although a varying, premium to the companies in addition to their *bonâ fide* capital outlay. It appears also that this is only fair and reasonable for the companies themselves, by hypothesis, must have faced the original risk of failure, and they have as yet only passed through those years of working in which their profits have presumably been smallest. Their shareholders may fairly anticipate that if left to themselves their dividends within the next few years will considerably increase.

"I understand that the Newcastle Corporation can borrow money for electric lighting purposes at such a rate and for such periods that a total of 5½ per cent. per annum would pay interest and sinking fund together. In a case where a corporation commences electric supply works and debits its costs every year, not only with interest on capital, but also with such instalment of a sinking fund as shall wipe the whole capital out in 40 years or less, I do not think it is necessary to debit working expenses with any large special allowance for depreciation, assuming, of course, that all renewals and maintenance of every kind are paid out of revenue as they occur. To find, therefore, the amount of earnings of each of the companies which would be available for payment of interest and sinking fund, I have subtracted from the gross profits in each year an amount of 1 per cent. on the capital, as representing such a depreciation allowance as the Corporation would probably have to make if the works were their own. If the committee think that this allowance is too small, under the conditions I have mentioned, any other figure can easily be inserted in the tables. Line 24 in the tables shows in each case the corresponding net profit—that is to say, the sum which would have been available in each year for the payment of 5½ per cent. on capital outlay if the work had been in the hands of the Corporation itself. Finally, in line 25 of the tables, I have entered the amount of capital on which this net profit would have been sufficient to pay the necessary percentage. It will be seen that in the case of the supply company in 1894 this amounts only to £40,800, although the *bonâ fide* capital expenditure of the company has been £51,752. In the case of the lighting company, interest and sinking fund could be paid on £59,400, as against an actual expenditure of £52,159.

"Taking the two companies together, then, the total capital actually expended has been £103,911, while the net profit (after allowing 1 per cent. depreciation), has been sufficient to pay 5½ per cent. on £100,200."

It would not be advisable for the Corporation to attempt to buy one company and not the other. This could only lead to competition, which must be keen and might be bitter, and it is doubtful whether the Board of Trade would sanction such a course.

"Practically, therefore, under existing conditions, if the Corporation could carry out the work itself with as great economy as the present companies do, it could just pay its way upon the actual capital outlay of the companies. Although I believe that the companies have not yet exactly formulated their desires in the matter of price, I yet understand that they would not sell, for reasons which I have already gone into, except at a very much higher figure than this. It therefore remains to be considered whether the Corporation, if it carried out the work itself, could effect any considerable economy in cost of working, and, further, what advantage to the city, especially in the matter of public lighting, might accrue from the fact of the electric light works being in the hands of the municipality."

There is one way by which the Corporation might economise—viz., by so connecting the two stations that one only need run continuously, the other supplying current during the time of heavy load only. This is electrically possible, though there are practical difficulties, and some considerable expense would be involved in carrying it out. It might result in a saving of working expenses of perhaps £1,200.

"Of course, in putting the matter in this way, I assume that the costs of management under the Corporation would remain as small as they are at present. I am not all sure, however, that this is a safe assumption, for certainly just now no money is wasted in this matter, and the only outlay which would obviously be saved is the directors' fees, amounting altogether to no more than £341 per annum in the two companies. But unless I am mistaken, this sum by no means represents the real value to the companies of the services of certain very able gentlemen who

Digitized by Google

have taken, and still take, a very active share in their development and management. In all probability the Corporation would have to pay a much larger sum for any equivalent services, and the total saving I have mentioned would be much reduced."

One important advantage the Corporation would gain would be in street lighting. Arc lamps might be more fully used At present there are about 20, which might be advantageously increased to 100 or more It would be fair to reckon the cost of such lamps at about £23 per annum, as against £42 now paid, which should include interest and redemption on capital specially raised for such lighting. The 80 additional lamps suggested would displace 360 gas lamps, and reckoning all savings, the additional cost would amount to about £520 per annum, or £6. 10s. per lamp. which is much less than the usual additional cost of street electric lighting; but in other places the lamps are seldom more than 60 yards apart instead of 90 yards, as in Newcastle.

Here, again, it is necessary to quote verbatim: "I think it is right that I should point out a further matter to you, in reference to the probable cost to the city of taking over the present works Although, undoubtedly, the works of the two companies are in such a state that they may be run by the companies themselves with very little additional expenditure beyond the annual outlay on additional plant and mains which I have already dealt with, yet I doubt very much whether the Corporation would be content to carry the work out in the same way. The buildings, for instance, of the lighting company, and the very crowded state of their station, would probably appear to a committee of the Corporation to demand radical change, although the company itself may quite well make them last a long time. The same remark may apply, in my opinion, to the mains (although not to the buildings) of the supply company, although there the additional capital expenditure would not be large. It is in the nature of things impossible for me to put before you any absolute figures which should represent the probable additional capital expenditure under such heads as these; but I think it is almost an universal experience in such cases that a transfer of property, whether to a corporation or otherwise, will almost certainly be followed by really large alterations and modifications under such circumstances as I have indicated.

"It appears from the considerations given above, that if the Corporation took over the work of the two companies it might, by running the stations jointly, economise in cost of running, and that it certainly could considerably increase the street-lighting at a cost to the municipality which would be very small. There still remains the crucial point, whether the actual economy and convenience would be sufficient to justify the Corporation as a matter of business in buying up the companies.

"I have pointed out that, taking the actual figures for the working in 1894, it might be possible for the Corporation to have done the same work for an amount of £1,200 less than it has actually cost the two companies together.

"I may say at once that I doubt very much indeed whether the Corporation actually could secure the whole of this saving, for many reasons, some of which I have indicated, but for the present purpose I will suppose that the saving can be obtained. This would raise the gross profit of the two stations together to £7,747,* the capitalised value of which at 6 5 per cent.—namely, 5·5 per cent. for interest and sinking fund, and 1·0 per cent. for depreciation—is, say, £119,000, or about 14·5 per cent more than the actual capital expenditure of the two companies. But against this has to be set the fact, which I have felt bound to bring before you, that apart altogether from any question of premium, and from all question of additional capital required for normal extensions, the Corporation would almost certainly find themselves involved in considerable additional capital outlay. This would swallow up a not inconsiderable portion of the 14·5 per cent., and would certainly not leave the possibility of paying any such premium as the companies may not improbably, and not improperly, desire.

"It does not, however, follow that what is true in 1894 fairly applies to the conditions which will exist in the course of a few years, when the business has largely increased. With the object of estimating the probable prospects in this direction, I have collected the figures given in Tables 1 to 4, and have very carefully studied them, both in the tables and in their graphic present ment in the accompanying diagram. I am sorry to say that I have found found myself driven to the conclusion that it could not pay the Corporation to purchase the works and goodwill of the two companies at any price covering a premium approximate to that which has been suggested by one of them. I have arrived at this conclusion in several different ways, the details of which it is unnecessary that I should state at length. The following figures, however, indicate generally one of the lines of reasoning which I have followed out: The actual capital outlay of the companies has increased fairly regularly year by year. and I do not see any sign that this rate of increase is going to diminish. It is true that the supply company expect to be able to increase their output somewhat by replacing the dynamos, and driving the present engines at a higher power This however, will not go very far, and both companies have their present buildings fully occupied by their present plant. and will soon be compelled to extend, while the supply company will soon have to purchase its land. The mains also, as well as the expenditure in transformers and meters, must increase continually as new consumers come on. The total revenue bears an approximately constant ratio to the capital expended, which ratio may be taken as about 15·25 per cent. It seems to be rather diminishing than increasing. The mean ratio of working expenses to total revenue was, in 1894, 58 8 per cent. If the Corporation had been carrying on the work of 1894, and had been able to effect the whole of the saving above assumed. this ratio would have fallen to 51 per cent. From the tables it will be seen there is no indication of this ratio falling very fast, although no doubt, it will fall. In an extreme case, which has not yet been reached by any corporation or company in Great Britain. I may assume that the total costs are presently reduced to 2d per unit sold, which would be, say, 44 per cent. of an average price of 4½d. per unit. so that the cost would be 44 per cent. of the revenue.

"Taking, then, the revenue as being 15 25 per cent. of the capital expended, and the total costs as reduced to 44 per cent. of the revenue, there would be left as gross profit an amount equal to 56 per cent of the revenue, or about 8 5 per cent. of the normal capital; 5·5 per cent. is required for interest and sinking fund and 1 per cent. for depreciation, or 6 5 per cent. in all. so that the calculated gross profit would be sufficient to pay this percentage on a capital increased in the ratio of 8·5 to 6 5. or 30 per cent. In other words, if the Corporation were to buy up the companies at their present capital expenditure. plus 30 per cent; if it incurred no further capital expenditure of its own beyond the normal rate of increase; if it realised a far greater economy in working costs than has been attained by either of the companies, or, indeed, by any other company or corporation throughout the country as yet. it might just succeed in making the scheme pay its way, with the allowance for interest, sinking fund and depreciation which I have mentioned. I feel, on the one hand, more than doubtful whether the assumed reduction in costs can be reached (considering how economically the companies are now working), and, on the other hand, I feel sure that there would be considerable additional special capital expenditure, so that as a matter of safe finance I cannot think that it would be possible for the Corporation to buy up the companies if anything more than a nominal premium were to be asked. Obviously, if the purchase were made, the premium would have to be different in the two cases. As to what is reasonable in this respect, from the point of view of the companies, I have already expressed my opinion.

"As my final conclusion in this matter may seem at first sight to be at variance with the very successful results obtained by various corporations in working their own electric lighting works at a profit, I may point out once more that the whole difficulty arises from the low price charged per unit. (I have here taken the 6d. as including meter rentals.) If the Corporation could increase the price to 6d. per unit (as they are entitled to do by Act of Parliament), the whole difference, amounting to about 30 per cent. of the gross income, would go to net profit, and would increase the present capitalised value of the companies, at 5·5 per cent., from £100,200, as given in paragraph 28, to about £190,000. I cannot suggest to the Corporation that they should raise the prices, for I presume this is practically out of the question, but I emphasise the matter again, because it is really the key of the whole position."

The refuse destructor is touched on as a source of power. but the saving in coal would not justify a third station and new mains, and the report concludes as follows: "I am very glad to acknowledge here the cordial and courteous help which I received throughout my investigations from all the officials of the companies, and the very full way in which they have given me the information for which I have found it necessary, in your interests, that I should ask. "ALEX. B. W. KENNEDY."

Table 5 is appended. The remainder of the tables and diagrams, while extremely valuable, are too bulky to print *in extenso*. The information is of more value as a record than of public interest, and the companies might reasonably object to the publication of so minute an analysis of their business.

TABLE 5.—Capital per Lamp Connected.

Company or corporation.	Capital.	No. of 8-candle lamps connected.	Capital per lamp connected.
Metropolitan (1893)	£585 932	166.000	£3·53
St. Pancras (1893)	96,085	30.326	3·17
Brighton	119 382	38 249	3·12
Manchester	127,985	42 635	3·00
Leeds	64,118	21 720	2 95
Bournemouth	40,536	14,552	2·79
Cambridge	31,503	11,644	2·71
Chelsea	119,705	47 286	2·53
Westminster	411,019	167,703	2·45
Glasgow	120,978	53,156	2·28
Newcastle (Lighting Co)	52.159	23.520	2·22
Newcastle (Supply Co.)	51,752	23,430	2·21

* "There is nothing to add to this for the arc lighting, for I have assumed that this is done at its actual additional net cost, in which, therefore, no profit would be covered."

LEGAL INTELLIGENCE.

ALLEGED BREACH OF LICENSE.

We hear that the Edison and Swan Company have commenced legal proceedings against a leading electrical firm, who are one of their licensees under the company's holders patents, for breach of the license in giving to customers a larger discount than the allowed maximum. For some time past there have been rumours that some of the licensees were selling holders at a lower price than that fixed by the company under the terms of the license, and that recently a committee of the licensees has been formed in order to

Digitized by Google

establish "an honourable understanding" among the licensees that this underselling should be discontinued. The terms of the license are very stringent—viz.:

"The licensee shall not make or allow any discount, commission, rebate, return, gift, or allowance to customers greater than the discount from time to time allowed by the company."

The Edison and Swan Company gave notice on December 31 last in a circular letter that should any future breach of this condition be proved that they would take legal proceedings for an injunction and for damages. It is for the good of all the licensees and for the trade generally that the terms of the Edison and Swan license should be maintained, and it may be hoped that the legal proceedings which are now being instituted will put an end to any unfair advantage being taken by some of the licensees against others.

COMPANIES' MEETINGS AND REPORTS.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.

The ordinary general meeting of this Company was held on Wednesday at Winchester House.

Sir John Pender, M P., presided, and, in moving the adoption of the report, stated that the receipts for the half-year ended December 31 last had been £104,926, or £10,247 in excess of those of the previous half-year. The total charges for the half-year had been £36 772, showing an increase of £16,503, which was owing to the fact that heavy expenditure for repairs of cable and renewing both shore ends at Pernambuco fell upon the half-year under review, while there were no similar expenses in the previous six months. Taking both receipts and expenses into account, there was, after providing for income tax, a net profit for the December half of £61 822, showing an increase over that of the June half of £2.029. As usual in the first half of the financial year, two quarterly interim dividends at the rate of 6 per cent. per annum had been paid leaving £24,324 to be dealt with. The directors had transferred £20,000 of this amount to the reserve fund, and they carried forward the balance. The reserve fund now amounted to £722,000, but a strong reserve was absolutely necessary for such a company as theirs. The directors were endeavouring to make satisfactory arrangements with the Brazilian Government, whether the latter acquired the coast cables or not, for the working of the traffic, in a way beneficial to both the Government and the people of Brazil and to telegraph companies also. The lines of the Pacific and European Company, in which this Company was largely interested, had now been opened for a year, and had worked with satisfactory results. The sum of £55,660 appeared in the balance sheet as paid for 5,566 shares of £10 each in the Azores Company, which might eventually connect the present system with the North American continent. After referring with great regret to the death of Mr. Fuller, the late managing director, he stated that when the question of the purchase by the Government of the cables of the Western and Brazilian Company was disposed of the Brazilian Submarine Company would have to deal with the Brazilian Government, with whom, for 21 years of their existence, they had worked in the most friendly relations. If any Government wanted to maintain a thoroughly efficient system of submarine telegraphy they must act in touch with the companies who conducted it, and the different companies ought to act always as one.

Mr. Brodrick, M.P., seconded the motion, which was unanimously adopted.

CHINA AND JAPAN TELEPHONE COMPANY.

The ordinary general meeting of this Company was held on Tuesday at the offices, Austin Friars, Mr. H. Grëwing presiding.

In moving the adoption of the report (which stated that, after charging debenture interest, the revenue account showed a credit of £387), the **Chairman** remarked that the amount received for subscriptions had been better than in the previous year, and in so far the Company was making steady, though slow, progress Owing, however, to various circumstances partly through the war, and partly on account of epidemics—the sales had fallen off to some extent, as had also the profits, which were also adversely affected by the decline in exchange. It was hoped, however, that these matters would rectify themselves in view of the recent rise in silver and the conclusion of the war. China had so far not taken any more kindly to telephones than it did in former years, but now that the war had changed the condition of things, the Chinese might alter their views on the subject, and might come under the Company's exchanges.

Mr. Thomas Lloyd seconded the motion, which was carried.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.

The report of this Company for the second half of 1894 states that the amount to credit of revenue was £33,243, against £34,265 for the corresponding half-year of 1893, and that the expenses have been £23,613 against £22,602, leaving a balance of £9 629, which, with £2,850 brought forward, makes a total of £12,479. It is proposed to pay a dividend of 6s. per share on the first and second preference shares, and to carry £710 forward. The traffic receipts show a decrease of £1,948 compared with the corresponding period, and those for the current half-year show no improvement. The cost of repairs to cables during the half-year amounted to £10,501, being £952 more than that for the corresponding period, and the contract with the French colony of Guadeloupe expired on December 31, so that the colony's subsidy of £2,000 per annum is no longer payable. These and other losses of revenue have rendered the payment of any dividend on the ordinary shares impracticable.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Oldham.—The Corporation Electric Light Committee require tenders for supplying two 200-h.p. steam-engines and dynamos, steam-pipes, etc. Specifications and forms of tender may be obtained on application to Mr. Arthur Andrew, Gas and Water Offices, Oldham, to whom tenders are to be sent, endorsed "Tender for Engines and Dynamos," on or before the 28th inst.

Hanley.—The Corporation invite tenders for the supply, delivery, and erection complete of two Lancashire boilers and fittings, including steam receiver; water-tank and girders; arc lamps and posts; high and low pressure cables, street boxes, cast-iron pipes, etc., in certain streets in the borough; transformers, switches, etc. Forms of tender may be obtained, and specifications and plans inspected, at the office of Mr Joseph Lobley, borough engineer and surveyor, Town Hall, Hanley. Tenders must be sent in to the borough engineer before the 27th inst.

Brighton.—Tenders are invited by the Corporation for (*a*) the preparation, supply and delivery at Brighton of cast-iron lamp pillars and copper canopies for electric light arc lamps; (*b*) the preparation, supply, and delivery at Brighton of cast-iron and drawn-steel bracket posts for suspending electric light arc lamps. Drawings may be seen, and specifications and forms of tender obtained, at the office of the borough engineer and surveyor at the Town Hall, Brighton, on payment of £1. 1s. for each specification. Sealed tenders, addressed to Mr. Francis J. Tillstone, town clerk, Town Hall, Brighton, and endorsed "Tender for Cast-Iron Lamp Pillars" or "Tender for Iron and Steel Bracket Posts," must be sent to the town clerk's office at the Town Hall before 10 a.m. on May 27.

BUSINESS NOTES.

Walsall.—The Town Council has agreed to a recommendation of the Property Committee that the Town Hall be illuminated by the electric light.

Hampstead.—The electrical engineer to the Hanley Corporation, Mr. G. H. Cottam, has been appointed chief electrical engineer to the Vestry.

Train Electric Lighting—The London, Tilbury, and Southend Railway Company have adopted a capital improvement in lighting the carriages of their trains by electricity.

City and South London Railway.—The returns for the week ending May 12 were £832, compared with £905 for the corresponding period of 1894, being a decrease of £73.

Rhyl.—The Urban District Council has received an application from a Birmingham firm asking for permission to construct an electric railway between Rhyl and Prestatyn.

Wells.—A tender from Mr. Dixon Brown, for publicly lighting the city by electricity, at £350 per annum, has been accepted by the Corporation for three years from June, 1896.

Southport.—Circulars are being issued by Mr. Ellis, the borough electrical engineer, setting forth the probabilities of a considerable abatement shortly in the price of current supplied.

Penistone.—The Board of Guardians have resolved to accept the offer of Messrs. Pettitt and Hards to send in specification and scheme for the supply of electric light to the workhouse.

Concert—The City Electric Light Athletic Club held a very successful Bohemian concert on May 11, at the Three Lords' Hotel, Minories, E C. The chair was taken by H. F. Jackson, Esq.

Brechin.—A communication has been read to a meeting of the Police Commission from the Board of Trade intimating that they were not to proceed with the Brechin electric light provisional order.

Fairfield (Buxton).—The Urban Council has agreed to a proposal to form a lighting committee to take into consideration the question of lighting the district, and to make enquiries respecting the electric light.

King's College.—The annual dinner of old students of King's College, London, will be held at the Holborn Restaurant on Monday, June 24, with the Right Rev. the Lord Bishop of London, D.D., in the chair.

Buenos Ayres—The Government have contracted with Messrs. Bonison and Mautalen for the construction of a building for the electric light station for the illumination of the port works. The cost is put down at 49,450dol.

House Installation.—We are informed that the Duke of Montrose has placed the electric lighting of his new house in Pont-street, London, in the hands of Messrs. Drake and Gorham, of Westminster. The number of lights will be about 130.

Taunton.—The Electric Lighting Committee of the Town Council has reported that Prof. Fleming, D.Sc,, had visited the town, inspected the electric light works, and made many valuable suggestions, which he promised to embody in a report.

Digitized by Google

Consolidated Telephone Construction and Maintenance Company.—The directors recommend a dividend at the rate of £1. 10s. per cent. per annum, less income tax, for the year ended March 31 last. The transfer-books will be closed from the 18th to the 21st inst., both days inclusive.

Milver Portable Electric Battery Syndicate, Limited.—This Company has been registered with a capital of £20,000 to acquire certain patents and inventions relating to improvements in primary batteries, and to develop and turn to account the same; and as engineers and electricians generally.

Worcester.—The clerk to the Town Council reported that with regard to the lighting of Stanley-road, Vincent-road, and Cecil-road, the Electricity Committee were awaiting the result of an experiment with incandescent lamps in Friar-street before proceeding with the lighting of other streets.

Ipswich.—The Electric Lighting Committee of the Town Council, for economic reasons, recommends that on further steps be taken to obtain a provisional order for electrically lighting the borough; and that Prof. Kennedy, who visited Ipswich on several occasions, be paid 100 guineas for his report.

Windsor.—The clerk to the Urban District Council has reported that the provisional order has been granted by the Board of Trade with reference to the electric lighting of Windsor. He added that the only thing required now was the sanction of Parliament, and when that arrived it would be duly advertised.

Glasgow Electric Lighting Revenue.—Up to April 24 the amount collected in electric lighting rental was £15 528, as compared with £13 364 over the corresponding portion of the preceding financial year. In this branch of the lighting department there was an increased revenue, which amounted to £2,164

Bootle —The Town Council have passed a recommendation of the Electric Lighting (Special) Committee that the electric light installation in the Town Hall and adjacent buildings be placed under the control of the Parks and Baths Committee, and that the Electric Lighting (Special) Committee be dissolved.

Dover.—Preparations are being made to lay an electric light main to the turret of the Admiralty Pier, where the current not only will be used to illuminate the turret and engine-room, but, in addition, will work a powerful search-light. A dynamo will also be placed inside the turret machine-room in reserve.

Metropolitan Asylums Board.—At a recent meeting the Brook Hospital Committee were authorised to employ Prof. A. B. W. Kennedy, LL.D., F.R.S., to design the installation of the electric lighting of the Brook Hospital, and to draw the necessary reports, plans, and specifications, and supervise the execution of the works, at a commission of 5 per cent. on the cost thereof.

Derry.—The Lighting Committee of the Corporation has accepted Messrs. Siemens Bros.' tender for carbons, samples of which were received from various firms. They cost the Corporation about £300 a year. It was agreed that the experiment made by Mr. Christie in lighting the City Hall clock by electricity with the ultimate view of lighting it permanently in that way was a success.

Northampton.—The Highway and Lighting Committee of the Town Council has recommended that the Market-square be lighted with four electric lamps of 1,000 c.p. each (two to be switched off at midnight), at an annual cost of £70, in accordance with the estimate of the electric light company, but after a long discussion an amendment, referring the matter back, was carried by 13 votes to 7.

County of London Tramways Syndicate, Limited.—This Company has been registered by Ashurst and Co., 17, Throgmorton-avenue, E.C., with a capital of £5,000 in £10 shares. Its object is to establish, construct, and maintain rail and tram roads, electric lighting, and other works, and to carry on the business of general contractors for public or private works in any part of the world.

Cardiff.—Several sums in the expenditure of borough account have been marked down as arrears which should have come into previous estimates by a special revising committee appointed by the Cardiff County Council. A sum of £800 was set down for lighting the Town Hall by electricity, and it was decided to apply for borrowing powers with respect of £300 as well as for £400 for lighting the market by electricity.

Worcester.—The Electricity Committee of the City Council have reported having arranged with the Streets Committee for the use of the London-road weighing-machine house as a transformer-chamber, and that arrangements have been made for the police institute to be used as an office for the electrical engineer, and the Council were recommended to authorise the office being connected with the electricity mains for testing purposes.

Aberystwyth.—The Public Lights Committee of the Town Council has recommended that the Council should avail themselves of the services of Mr. A. H. Preece, C.E., in the matter of testing the electric light and other matters connected with the proposed installation. The recommendation was passed. A recommendation of the Public Works Committee regarding the erection of electric lamp-posts at a cost of £900 was also accepted.

Mechanical Ventilation in Steamships.—The Russian Steam Navigation Company having been so satisfied with the efficiency of the "Baird-Thompson" improved system of mechanical ventilation introduced into their fleet some time ago, they have contracted with Messrs. Baird, Thompson, and Co., Limited, of London and Glasgow, for the introduction of their system into the large new steamers at present being built for them in this country.

Mill-Lighting.—A complete installation of 1,200 lights is being fitted in the Valley Mills of Messrs. James Nelson and Co., of Nelson, Lancashire. The installation is being carried out by Messrs. Coates Bros., of Nelson. The dynamos are being built by the Coventry Electrical Engineering Company, Limited. There will be two 600-light dynamos and one 250-light dynamo. The 600-light dynamos will be driven by ropes from the main shafting, the 250 light dynamo by a separate engine.

Cheltenham.—At the last meeting of the Town Council, Alderman Norman, in moving the adoption of the minutes of the Electric Lighting Committee, said he had very little doubt that within a short time the electric light would not be the slightest burden on the town. The largest item in the accounts was the £3,500 to be paid to Messrs. Siemens, the contractors. They still held one-fourth of the amount due to the contractors until the machinery had been running the specified time.

Church Electric Lighting.—The Dover Electricity Supply Company has received a letter from the vicar and churchwardens of Buckland Church, Dover, in which they say that after a month's trial of the electric light in Buckland Church the result exceeds their most sanguine expectations, and from whatever point it is compared with gas it is found well ahead. For the three months ending March 31 the cost of gas was £3. 18s. 3d., while with electricity, based upon the consumption during the last month, it would have been £3. 5s. 1d.

Appointment Vacant.—The Corporation of Tunbridge Wells require a resident engineer to take entire charge of their electric lighting works. Applicants must have had experience of similar work, must be capable of superintending additions and extensions of the works, and the person appointed will be required to devote the whole of his time to the performance of his duties. Salary £250 per annum. Applications, stating age and experience, and accompanied by copies of three recent testimonials, to be sent to Mr. W. C. Cripps, town clerk, Town Hall, Tunbridge Wells, by the 25th inst.

Blackpool.—The Town Council have decided, upon the recommendation of the Electric Lighting and Tramways Committee, that the rectifying apparatus be retained by the Corporation, subject to a guarantee by Messrs. S. Z. de Ferranti. Further decisions were to the effect that 4½d. per unit be the amount charged the Corporation until further notice for public arc lighting in the borough; and that the necessary cable to complete the Church-street district lighting be procured under the directions of the chairman (Councillor Pearson), Mr. Hammond (consulting electrical engineer) and the borough electrical engineer.

Bangor.—At the last meeting of the City Council, Dr. Grey Edwards proposed the appointment of an electric light committee. They hoped shortly, he said, to receive the report of the Edison-Swan Company, and it would be very advantageous to have a committee to go into the question thoroughly. They had already authorised the Water and Gas Committee to obtain the services of an electrical engineer to go into the question of plans and estimates. He thought it was necessary to proceed at once and to decide whether they would relieve the gasworks by the addition of electric light in the city. After some discussion a committee was formed.

Stroud.—The clerk to the Urban Council has received a letter from the district manager of the National Telephone Company in reference to the scheme to place Stroud in direct telephonic communication with Gloucester, Bristol, and other parts of the country. The letter pointed out that the scheme would involve a very large expenditure, by no means fully covered by the preliminary subscribers, and the company, therefore, relied upon the support of the Council in furtherance of the scheme. Plans accompanied the letter with the suggested position of the poles necessary to reach certain points to be connected. The Council accepted the company's plans and terms of agreement, subject to certain protective regulations.

Leyton (Essex).—The Hall Building Committee of the Urban Council has reported that the estimated cost of lighting the public hall by electricity is £1,250. The committee were of opinion that the buildings, including the present offices, should be lighted by electricity, and they recommended that tenders be invited from several firms. Mr. Trumble complained that in connection with the new hall they were always having extras sprung upon them It was now suggested that they should have electric light at a cost of £1,250, or £1,000 more than was allowed for lighting in the specification. He moved that the report be referred back to the committee, and that details be presented at the next meeting. Mr. Dick seconded this, and it was carried.

Bowness.—At the last meeting of the Urban District Council the clerk read the agreement between the Council and Messrs. R. H. Fell and Sons, in the matter of lighting the village by electricity. The agreement stated that the Council should pay 25s. per lamp per annum, the company to rebate £20 from the charge, this money to go to the payment of an inspector. The company would supply 35 new lamps of 25 c.p. for the main road, the rest of the lamps to be 16 c.p. The company were further required to keep the lighting system in working order to the satisfaction of the Council, so that there should be no interruption to the lighting, and to pay 1d. per hour for any that were not lighted. Only the incandescent lamps and globes were to be paid for by the Council. The agreement was sanctioned by the Council.

Killarney.—The Clerk to the Town Commissioners stated at a recent meeting that some time ago they passed a resolution directing him to write to the Board of Trade to know who the officers of the electric light company were, and the Board's reply was as follows: "In reply to your letter of the 27th ult., I am directed by the Board of Trade to inform you that Mr. George Pearson, of her Majesty's Treasury, Whitehall, London, S.W., is

Digitized by Google

the auditor appointed by them to audit the accounts of the undertaking authorised by the above-mentioned order, and that Mr. James Downes is the secretary of the Killarney Electric Light Company, Limited. I am further to inform you that the accounts of the undertaking for the year 1892 and 1893 have been audited by Mr. Pearson." The Chairman remarked that some outside people seemed to think that there was no electric light company at all.

Liverpool.—The report of Sir Frederick Bramwell, the expert who had been engaged to examine the plant and other property of the Electric Supply Company, Limited, on behalf of the Corporation, has been presented to the Special Lighting Committee of the City Council. It described the condition of the whole of the machinery and appliances. The conclusion to which Sir Frederick arrived was that everything was satisfactory, and that the purchase would place the Corporation in possession of a valuable property. Mr. Harcourt E. Clare, the deputy town clerk submitted the draft of the agreement with the company, which was considered. Its adoption is subject to the approval of the Electric Supply Company. The total amount of the purchase is £400 000. The committee decided to retain the services of Mr. Holmes, the managing engineer of the company, at the salary he is now receiving.

Hove.—At a meeting of the Urban Council, Mr. Usher Robins directed attention to the charges of £793 for gas and £47 for the electric light, making an expenditure of nearly £1,000 for the quarter. He thought now that the electric light company had been in existence for about three years it was time the Council had some information from the committee as to which they considered the best mode of illuminating. Mr. C. T. Cheesman, in reply, said the committee, or rather the surveyor, was preparing a report relative to the cost of the gas and of the electric light. At a subsequent meeting of the Library Committee, Mr. Usher Robins said he thought the whole of the inhabitants would be benefited if the electric light were more generally used. He was glad to know that they would shortly have a report as to electric lighting. Captain Creagh said if they burned the electric light for four hours out of the 24 they would pay exactly double the amount charged to people living in Brighton. The Corporation of Brighton charged 4d. per unit, and they paid the company in Hove 8d.

Western and Brazilian Telegraph Company, Limited.—The report of this Company states that the total earnings during the second half of 1894 amounted to £82,815. against £80,338, showing an increase of £2,476 compared with 1893, and that the working expenses amounted to £36,403, against £35.592 Including the amount brought forward and dividends received, the balance was £56,660, from which has been deducted £11,601 for debenture interest, and £5 000 for the debenture redemption fund, leaving £40,059, of which £8,000 has been placed to the reserve fund The directors now recommend the payment of 6s. per share, tax free, for the half-year on the ordinary shares, making, with the dividend paid in November, £3 per cent. for the year, leaving £2 846 carried forward. In the case of divided shares, 4s 6d. will go to the "preferred" shareholders and 1s 6d. per share to the "deferred" shareholders. The Company's action against the Brazilian Submarine Company was heard on March 8, and decided on all points in the Company's favour. Six thousand pounds per annum is now being paid by the Brazilian Submarine Company.

Perth.—About a month ago, at a meeting of the Waterworks Commissioners, Mr. Davidson, the manager, produced a scheme and cost of lighting the works with the electric light, and the Commissioners agreed to allow him to proceed with the work. Contracts were taken and the offer of Messrs. Lowden Bros., of North Tay-street, Dundee, was accepted. The contractors have now completed their work At the inauguration of the light, Lord Provost Dewar said they had better light, more of it, and at less cost than gas It was also interesting in so far that, as that was the first installation of the electric light in the public departments in Perth, he believed it would be the beginning of a further extension of it. Mr. Davidson said that he would be able to give them enough power to light their new municipal buildings; while the electrical engineer said that the water at present running to waste at the foot of Mill-street could also produce enough power to light the municipal buildings. Mr. Davidson stated that at present there was enough power running to waste at the City Mills which would light a large portion of the streets and also the public library.

Ulverston.—Mr. John Poole, as clerk to the Ulverston Urban Council, has been granted an interview by the Rural District Council on the subject of electric lighting. He said they would be aware that under the agreement between the Windermere District Electric Supply Company and the local authorities interested power was given at the end of 10 years to purchase the distributing arrangements of the company upon the terms set forth in the agreement. The Board of Trade had, however, in the order sent down for their approval, inserted certain words to the effect that no sale under this purchase clause should be valid or binding unless the consent of the Board of Trade was given thereto. So far as the Ulverston Urban Council was concerned it had already passed a resolution objecting to the purchase being subject to the consent of the Board of Trade, and Mr. Tosh, the chairman, had arranged to see the Board of Trade on the subject in London. He (Mr. Poole) had written to this effect to Mr. Morse, the solicitor of the Electric Supply Company, who had replied that he did not think there would be any difficulty in getting the Board of Trade to omit the objectionable words. He had laid the matter before the Rural District Council, in order that they might consider whether they should not pass a similar resolution. Councillor Marshall moved a resolution objecting to any modification of the agreement made by the company in the sense of restricting the power of free sale between the company and the Council. The motion was agreed to.

Eccles.—The Town Council have confirmed the proceedings of the Electric Lighting Committee which included reports of the visits they had made to Wolverhampton and Altrincham. At the former they were met by the Mayor of the borough, who is chairman of the Lighting Committee, several members of the committee, the electrical engineer, and the town clerk, and were very courteously treated, it appearing to be the desire of everyone connected with the Wolverhampton works to impart all information in their power, in order, as they said, to enable other corporations treading in their footsteps to put down as complete and perfect a station as possible On April 30 the committee, accompanied by the engineer (Mr. Clirehugh), and the town clerk, proceeded to Broadheath, to inspect the station established by the Altrincham and Bowdon Electric Supply Company, Limited, who had recently undertaken the lighting of the district. Mr. Fawcus and Mr. Cowan, of the Manchester Edison Swan Company, and the engineer met the committee, and explained the system, and also exhibited a map of the area of supply, from which it was seen that the undertaking has all the difficulties to contend with of a sparsely-populated area, consumers being in some cases few and far between.

Weston-super-Mare.—The following report has been laid before the Urban Council: "It will be remembered that your Local Board, some time since, went to the expense of nearly £500 to obtain a provisional order, by which they monopolised the power to introduce electric lighting into Weston super-Mare within a given period. The powers secured under such order have never been utilised, the representatives of the ratepayers being content to watch the expensive experiments that have been made by other towns. I have repeatedly asserted that the 'light of the future' is not yet perfected, and the longer the adoption of any particular system is delayed the better will it be from a financial point of view. There are those, however, who appear anxious to rush the matter at any cost, holding up as a bugbear the possibility of a private company stepping in and usurping the powers hitherto enjoyed by your governing body. Public companies, however, as a rule are not so rash as to expend their capital without some prospect of a remunerative return. If an electric lighting company should determine on making Weston super-Mare the basis of their operations it is not probable that your Council would hand over the public lighting to their care and without this the revenue from private consumers would make a sorry return on the investment. Your Council have now as much as ever the entire matter in their own hands, and a renewal or extension of the provisional order, now expiring, will tide them over a difficulty which just now is being considerably magnified."

Islington.—In a report issued on Wednesday by the Finance Committee of the Islington Vestry they submit to the Vestry a correspondence which has passed between the vestry clerk and the comptroller of the London County Council with reference to a loan of £51,000, which the Vestry require for electric lighting purposes. It is stated that the Finance Committee of the Council, having obtained the consent of the Treasury, are prepared, as an alternative to their proposal, to sanction the loan for land, buildings, and bare copper mains (estimated to cost £18 000) for 50 years, and for all other machinery (estimated to cost £33,000) for 20 years, to recommend the Council to sanction a mean period of 42 years for the repayment of the whole amount "on condition that if any portion of the machinery requires to be renewed during this mean period, it shall not be made the subject of a new loan." The Vestry's committee point out that acceptance of this condition would render it necessary, besides providing for the annual repayment of capital and interest, to further burden the undertaking (or possibly the ratepayers) during its earlier years by the creation of a renewal fund to provide not only for the wearing out of machinery, but for the possibility, owing to the advance constantly taking place in electrical science, of portions of such machinery becoming obsolete during the currency of the loan. Further, it is considered doubtful whether the Council, in sanctioning a loan, has power to limit the period for repayment provided by Section 8 of the Electric Lighting Act of 1882, and Section 190 of the Metropolis Management Act, 1855. Hence, the Vestry's committee advise that counsel's opinion be taken on this point, and meanwhile the vestry clerk make a formal demand for the County Council's sanction to the loan.

Brighton.—At a recent meeting of the Town Council, Alderman Brigden proposed the confirmation of the committee's proceedings of April 26, withdrawing the resolution as to the acceptance of a tender for the extension of the electric generating station. The motion was negatived. This referred to the six tenders which were received for the extension of the Corporation electric generating station, and it was resolved to accept that of Messrs. J. Longley and Co., Crawley, for £12,169. At a meeting of the Lighting Committee it was resolved that the electric lamp-pillars for the lighting of the Marine-parade be of similar designs to those at present on the King's-road, and that tenders be invited by public advertisement for the supply of 45 such pillars. A design submitted by the borough surveyor for the lamp-pillars to be erected in the other streets which are to be lighted by electricity was approved, and it was decided to advertise for tenders to supply 80 such lamps. A design for the canopies of the electric lamps to be erected on the Marine-parade has been approved, and it was resolved to advertise for tenders. The question of increasing the lighting in Regency-square was deferred for the present, in view of the possible extension of electric street-lighting. These recommendations were adopted. On the 10th inst. the report of

Digitized by Google

the Works Committee, recommending, after further consideration of the tenders for the extension of the electricity generating station, that the Council should accept Messrs Field and Co.'s tender to perform the work for the sum of £12,086 was submitted. Alderman Brigden, in moving the adoption of the report, said the matter was before the Council at the last meeting, when another tender was recommended, but the report was then withdrawn in consequence of a communication from the Lighting Committee. It was found that after deducting certain work done by the Council, Messrs. Field's tender was the lowest by £39. The mistake occurred through a wish to expedite matters. The motion was carried.

PROVISIONAL PATENTS, 1895.

MAY 6.

8966. **Improvements in meters for measuring currents of electricity, part of the invention being applicable to electric motors for driving astronomical clocks and other like apparatus.** Henry Augustus Rowland, 55, Chancery-lane, London.

8972. **Improvements in electric railways.** William Lawrence, 29, Broadway, New York.

8994. **Improvements in and connected with arc lamps.** William Jandus, 18, Southampton-buildings, Chancery-lane, London.

MAY 7.

9010. **Improvements in electric railways.** George Edward Baird, 5, John Dalton-street, Manchester. (Complete specification.)

9050. **An improved process for the production of lead compounds or other metallic compounds by electrical means.** Ernest Bailey, Tom Cupper, Arthur Lancaster Stobbs, William Alfred Wilson, and James William Pollard, Billiter-buildings, London

9056. **Safety appliance for electrical circuits.** Siemens Bros. and Co., Limited, 28, Southampton buildings, Chancery-lane, London. (Messrs. Siemens and Halske, Germany.) (Complete specification.)

MAY 8.

9111. **Improvements in telephonic receivers.** Cornelis Dirk Janszen, 55, Chancery-lane, London. (Arsène Gerbert, France.)

9112. **Improvements in the method of and means or apparatus for effecting multiple telephonic communications.** Cornelis Dirk Janszen, 55, Chancery-lane, London. (Arsène Gerbert, France.)

9132. **Improvements in electrical ceiling and wall connectors.** Charles Mark Dorman and Reginald Arthur Smith, Ordsal Electrical Works, Salford, Manchester. (Complete specification.)

9144. **Electrical soldering apparatus.** Gustav Binswanger and Francis William Ball, 71, Queen Victoria-street, London.

9146. **Improvements in and connected with arc lamps.** Hermann Niewerth and Regina Niewerth, 1, Quality-court, Chancery-lane, London.

9158. **An electric light bath.** George Frederick Redfern, 4, South-street, Finsbury, London. (W. Gebhardt, Germany.)

9167. **Improvements relating to telegraphic working through cable lines.** Joseph Arthur Lovel Dearlove, 24, Southampton-buildings, Chancery-lane, London.

9176. **Improvements in armatures for dynamo-electric machines.** Williams Brooks Sayers, Henry Alexander Mavor, William Arthur Coulson, and Samuel Mavor, 46, Lincoln's-inn-fields, London.

MAY 9.

9180. **A hand hoist for raising and lowering arc lamps.** George Wilson Lunn, 21, Yorkshire-street, Oldham.

9184. **An improved electric motor called the "leader" electric motor.** Joseph Waddington, Edgar Waddington, and John Waddington, Fletcher-street, Bury.

9202. **Improvements in holders for incandescent electric lamps.** Jan Meines Huisman and Henry Charles Gover, 62, St. Vincent-street, Glasgow.

9206. **An improvement in glow lamps.** Henry William Handcock and Alfred Herbert Dykes, 5, Victoria-street, Westminster.

9217. **Improvements in electrical cut-outs or safety fuses, switches, and the like.** John Benjamin Verity, Plume Works, Aston, Birmingham. (Complete specification.)

9237. **Improvements in or connected with electric conductors for telephonic or other analogous purposes.** Henry Edmunds, 47, Lincoln's-inn-fields, London.

MAY 10.

9257. **Improvements in cells and diaphragms for use in electrolysis.** James Hargreaves, Farnworth-in-Widnes.

9262. **Improvements in incandescent electric lamps.** Arthur Bryce Mees and James Davis Pitt, Comberton Villa, Brettle Lane, Staffs.

9273. **Improvements in tubular electromagnets.** James Taylor, Heathercliff, Helsby, near Warrington.

9286. **Improvements in automatic electric switches and in their use for distribution of electricity, parts of which improvements are applicable to other automatic devices.** John Hopkinson, 5, Victoria-street, Westminster.

9312. **Improvements in electric conductors or cables.** Henry Edmunds, 47, Lincoln's inn-fields London.

9314. **Improvements in electric receivers or mechanism for actuating counting dials or the hands thereof.** Henry Lepaute, 323, High Holborn, London.

9323. **Heating, drying, and smoothing by electricity.** Leslie Bradley Miller, 2, Gray's-inn-road, London.

MAY 11.

9354. **Improvements in electric cooking and heating apparatus.** Guillaume Arnaud Nussbaum, 29, Ludgate-hill, London.

9372. **An electric oven.** Victor George Middleton and Douglas Neale, Broadway-chambers, Westminster.

9380. **Improvements in electrical-firing pistols for gun mountings.** Edward William Lloyd, of the firm of Sir W. G. Armstrong, Mitchell, and Co., Limited, and Ralph Thew Brankston, 24, Southampton-buildings, Chancery-lane, London.

9388. **Improvements in regulating appliances for arc lamps.** Rookes Evelyn Bell Crompton, 55, Chancery-lane, London.

SPECIFICATIONS PUBLISHED.

1894.

7950. **Electrolytical apparatus.** Guthrie.

8328. **Electric condensers.** Threlfall. (Threlfall.)

8731. **Electric batteries.** Froggatt.

10101. **Gripping tool for electric light, etc., fittings.** Binswanger and Gibson.

11225. **Arc lamps.** Bevis and Hirst.

12973. **Casting electric accumulator plates.** Hampel.

1895.

2916. **Electric distribution.** Devonshire. (Steinmetz.)

2917. **Electrical distribution.** Devonshire. (Steinmetz.)

5196. **Thermo-electric generators.** Cox.

5693. **Electric railways and tramways.** Berg and Tarbox.

NOTES.

Society of Arts.—The society's conversazione will be held at South Kensington Museum on Wednesday evening, June 19.

Lecture.—A paper on "Electric Lighting" has been read before the Beckenham District Council Electoral Association by Mr. F. A. Glover, of Queen Victoria-street.

Rouen Electric Tramways.—The work of laying the rails of the new electric tramways at Rouen is almost completed, progress having been made at the rate of 650ft. a day.

The Uses of Accumulators.—The adjourned discussion on Mr. J. C. Howell's paper on this subject will take place on Monday next at a meeting of the Northern Society of Electrical Engineers.

Electricity at the Berlin Exhibition.—A syndicate of firms belonging to the Society of German Electricians has been formed with the object of supplying electricity for light and power purposes to the Berlin Industrial Exhibition, which is to be opened next year.

Society of German Electricians.—The Verband Deutscher Elektrotechniker will hold its third annual meeting at Munich from July 4 to 7. The Ohm monument will be unveiled on Saturday, July 6. On Sunday an excursion will be made to the Starnberger See.

Degrees in Science in Engineering.—The University Commissioners have issued an ordinance ordaining that two degrees in science in engineering may be conferred by the University of St. Andrews—viz, Bachelor of Science in Engineering, and Doctor of Science in Engineering.

Constant Dielectric.—Prof. A. Volta has an article in *L'Elettricità* (May 12) "On the Constant Dielectric of Some Substances and Particularly of Glass," which is based upon experiments made by Prof. D. Mazzotio, particulars of which have appeared in the *Rendiconti* of the Accademia dei Lincei.

The Utilisation of Old Insulators.—Has it been reserved for the Bureau Central des Postes, Télégraphes, et Téléphones of Brussels to find out a profitable method of disposing of old insulators? In announcing a sale by auction of these articles, this official body remarks that they "will be sold *en masse* or in lots, and they can advantageously be utilised as borders for gardens"!

Electricity in Milan.—Some interesting particulars are given in a recent number of our Italian contemporary, *L'Elettricità*, concerning the development of the use of electricity in Milan. From there we gather that the number of incandescent lamps in that city rose from 3,300 in 1884 to 38,300 last year, and the number of arc lamps from 26 in 1884 to 629 in 1893, but only 624 in 1894.

Rather Premature.—A correspondent of *L'Etincelle Electrique* writes to the editor of that journal, somewhat prematurely, many may think, in view of the not infrequent revolutions of the political wheel, suggesting that the Tsar, while sitting at his palace in St. Petersburg, might open the Paris Exhibition of 1900 by pressing a button and deliver an inaugurative speech to his delighted French auditors by telephone.

Military Telegraphists.—The Telegraph Battalion of the Royal Engineers from Aldershot are to undergo their annual encampment in Woolverstone Park, Ipswich. An advance guard of 20 men arrived on Monday afternoon, and marched to the park to prepare the camp for the main body (numbering about 150), which will arrive on Saturday. The mounted men of the battalion, to the number of 70, will arrive by road on the same day.

Pride.—As our readers are aware, tenders are being advertised in this country for the electric lighting of Rangoon. This fact rouses the ire of *Indian Engineering*, which indignantly says: "Surely, with firms of such standing as Messrs. Octavius Steel, and others, who are specialists in this line, both in Calcutta and Bombay, advertising in India would have served as well, and saved the municipal coffers, which are reported as being very low." As the Scot observed, "May be aye and may be no."

A Bold Assertion.—The *Daily Chronicle* this week, with a calm disregard of fact, asserted that American engineers seem to be all agreed that steam railways are doomed within a quarter of a century, so far as America is concerned. This shows that it is unwise to generalise from a particular instance, the item apparently having been founded on the article by Mr. Joseph Wetzler (see *Electrical Engineer*, May 10, p. 539) in which he stated as his own opinion that all railways will be eventually operated electrically.

North-East Coast Institution.—We have received part 5 of vol. xi. of the *Transactions* of the North-East Coast Institution of Engineers and Shipbuilders, which contains Mr. Frank Caws's reply to the discussion on his paper on "An Account of Some Experimental Studies of Ship Acceleration;" discussion on Mr. W. C. Mountain's paper on the Design and Efficiency of Plant for the Transmission of Power by Electricity;" and a paper on "The Application of the Electric Arc to Machinery and Boiler Repairs" by Mr. Henry Foster.

Electricity in France.—The Compagnie Parisienne de l'Air Comprimé is establishing a large electric central station on the Quai Jemmapes; the Société Normande d'Electricité has ordered for the central station at Rouen (*L'Industrie Electrique* says) four Willans triple-expansion engines of 180 h.p. for driving four Alioth dynamos; and the Société de Traction Electrique (Heilmann) will also use Willans engines in the central station which it is proposed to build in the neighbourhood of Paris in connection with the projected electric railway.

Postal and Telegraph Routes.—Lord Rosebery is to receive a deputation from the Association of Chambers of Commerce on Friday next at Downing-street with reference to inter-Imperial postal and telegraph routes. The association at its Huddersfield meeting passed a resolution advocating inter-Imperial postal and telegraph routes between this country and the colonies, and between the colonies themselves respectively, without such routes passing through other countries. It is probable that the Chancellor of the Exchequer and the Postmaster-General will also be present at the interview.

Books Received.—Messrs. Longmans, Green, and Co. send us "The Telephone Systems of the Continent of Europe," by Mr. A. R. Bennett; and "Problems and Solutions in Elementary Electricity and Magnetism," by Messrs. W. Slingo and A. Brooker. The latter forms one of Longmans' elementary science manuals, and embraces the South Kensington papers for the years 1885-1894. We have also received the second edition of Mr. W. Perren Maycock's "A First Book of Electricity and Magnetism for the use of Elementary Science and Engineering Students and General Readers," published by Messrs. Whittaker and Co.

Electrical Communication with Light Stations. In reply to Admiral Field in the House of Commons on Monday, Mr. Bryce said that, in addition to the works recommended in the recent third report of the Royal Commission, there were still some works, recommended in

Digitized by Google

the first report, which had not yet been carried out. A sum of £11,000 had been placed at the disposal of the Board of Trade for the purpose of effecting electrical communication with light-vessels, etc., during the present financial year, and the Board were at present considering on which of the works recommended that amount—which was not sufficient for all—should be expended.

Closing Bulkhead Doors.—A telegram from Washington states that since the disaster to H.M.S. "Victoria," the officers of the United States navy have devoted much attention to the question of bulkheads. Chief Engineer Melville has now prepared several mechanical devices, which may be operated either by compressed air or by electricity, by means of which all the bulkhead doors of a vessel can be automatically closed at a moment's notice. The officer on deck or the man in the conning-tower, on seeing the danger, can, by simply pulling a lever, close every door instantaneously, after first having, by pre arranged whistle or bell, signalled warning to those below to hasten on deck or otherwise escape.

A New Malady.—A new malady has appeared in the telephone exchanges in America. The fatigue of listening continually at the receiver produces a humming in the ears, headache, and, finally, abscess of the tympanum. It is necessary to give an hour's rest every three or four hours to the employés. This trouble is most observable in California, and it is not known in the Eastern States, and may be due either to defective apparatus or to overwork. In examination before the Select Committee on Telephones, Mr. W. H. Preece called attention to the use of a small electric lamp which had been invented, and which, working in the call-wires, indicated "finished" or "through," and so obviated the voice calls which are sometimes so irritating.

Congress of Chambers of Commerce.—Invitations to a third congress of chambers of commerce of the Empire, which the London Chamber has decided to organise for June, 1896, have been sent by the London Chamber to chambers of commerce and other cognate bodies throughout the colonies. The first congress was held in 1886 at the time of the Colonial and Indian Exhibition, and the second in 1892, both being successfully carried through under the auspices of the London Chamber. The council of the London Chamber direct attention to the questions which might be usefully discussed by the congress, and which include light railways, and cable communication, construction, rates, codes.

Aluminium v. Picturesqueness.—The old struggle between utilitarianism, on the one hand, and beauty and historical associations, on the other, is ever being renewed. At the first meeting of the National Trust for Places of Historic Interest, etc., lately held, the Duke of Westminster presiding, reference was made to the Fall of Foyers. The British Aluminium Company proposes to dam, it appears, the three lakes in Stratherrick, above the fall, and submerge 300 acres of land, and it is contended that if this purpose be effected the cascade would become a thing of the past. The meeting expressed the hope that public feeling would be so aroused as to prevent this being done, and pronounced that the destruction of the fall would be a national loss.

Electricity Extraordinary.—The American newspaper Press is circulating a wonderful tale concerning a Chicago hotel which, it is gravely stated, is "heavily charged with electricity." The story runs that when one guest started to shave himself a huge spark leaped from the razor and startled him to such an extent that involuntary suicide nearly resulted. We are further informed that another guest stepped into a bath-tub and immediately howled lustily for assistance, being assailed with a sensation of having thousands of needles unceremoniously jabbed into his person. The employés of the hotel broke open the door and rescued the victim, who, however, is said to have experienced no bad effects from his marvellous bath. The tale concludes with the statement that the hotel is losing patronage, and will probably be pulled down!

Obligations of Electric Light Companies.—In answer to Mr. Weir in the House of Commons on Tuesday, Mr. Bryce said, "My honourable friend is not correctly informed as to the state of the law. Private electric lighting companies having statutory powers are under obligations similar to those imposed on local authorities, and are also prohibited from using overhead wires without the consent of the Board of Trade and the local authority. Private electric lighting companies not having statutory powers are subject to regulations for the protection of the public safety prescribed under the provisions of the Electric Lighting Acts, 1882 and 1888, although the use of overhead conductors is not prohibited by those Acts. Moreover, urban authorities under the Public Health Act of 1890 are empowered to make regulations for the prevention of danger or obstruction to the public from wires stretched over, along, or across any street."

Liverpool Engineering Society.—The following visits will be made to works during the forthcoming summer: Saturday, June 8, to the Liverpool Corporation reservoirs and filter-beds at Rivington—Mr. Jos. Parry, M.I.C.E., water engineer; Friday, June 21, and Saturday, June 22, to the main sewerage works, pumping station, and refuse destructor of the borough of Cambridge—Mr. J. T. Wood, M.I.C.E., chief engineer; Saturday, July 6, to the Snowdon Mountain Rack Railway in North Wales—SirDouglas Fox, M.I.C.E., chief engineer, and Messrs. Holme and King, contractors; Saturday, August 3, to the site of the Elan water supply of the Birmingham Corporation at Rhayader, Radnorshire—Mr. Jas. Mansergh, M.I.C.E., chief engineer; Friday, September 6, to the Sunlight Soap Works, Bebington—Messrs. Lever Bros., Limited, proprietors; and on Saturday, September 21, to the Wirral Railway Works—Sir Douglas Fox, M.I.C.E., chief engineer.

City Commission of Sewers and Telephony.—On Tuesday a meeting of the City Commission of Sewers was held at the Guildhall, Mr. H. T. Gordon presiding. Mr. H. Montague Bates, the clerk, reported that in order to ascertain the experience generally of telephone users in the City as to the efficiency and cost of the existing telephone service, he issued circulars to all the subscribers to the National Telephone Company as to whether the provision now made for the telephone service was adequate and whether it was expedient to supplement or improve the provisions, either by the granting of licenses to local authorities or otherwise. He had received 1,085 replies, from which it was quite clear that the existing telephone service was costly and inefficient. The Court referred the report to Mr. A. C. Morton, M.P., Mr. Bates, and the Remembrancer, to decide as to the best way of placing the facts contained in it before the Select Committee of the House of Commons now considering the matter.

Steam-Engines Bill.—The Select Committee to which the Steam-Engines (Persons in Charge) Bill, introduced by Mr. W. Allan, was referred, resolved, says the *Times*, after a somewhat heated discussion on Wednesday, not to proceed with the consideration of the measure, the fate of which is accordingly sealed for the present session. It appears that, in order to facilitate the passing of the Bill, Mr. Allan

Digitized by Google

agreed to adopt a suggestion from the Treasury bench excluding marine and other engines from its scope, and, pursuant to this arrangement, the committee were asked to take evidence only in relation to the clauses which would remain after the proposed alteration was made. A motion to this effect was carried by the casting vote of the chairman (Sir E. Hill), whereupon, Mr. Havelock Wilson and others having protested against the elimination from the Bill of provisions to which they attached especial value, it was decided, on the motion of Mr. Brunner, to take no evidence at all, but simply to send the measure back to the House.

Personal.—Mr. John Darney has been compelled to resign his position as honorary secretary to the Northern Society of Electrical Engineers owing to his removal from Manchester. His place has been taken by Mr. J. Vincent Swindells. Mr. Stanley Franklin, who has superintended the fixing of electrical machinery at Cheltenham for Messrs. Siemens Bros., was on Thursday last the recipient of a pleasing token of the appreciation felt by the chairman of the Electric Lighting Committee of the way he has carried out his work. Alderman Norman, at the conclusion of the dinner given in honour of the completion of the station, presented Mr. Franklin with a handsome walking-stick, and at the same time assured him that his efforts to give the Corporation satisfaction had not passed unnoticed. This present is a new departure, and we are pleased to see that at Cheltenham the chairman of the Electric Lighting Committee has recognised the value of the services of engineers placed over the work by the contractor. We understand that during the month in which Mr. Franklin had to run the plant no hitch occurred in the lighting.

The Electric Lighting of Railway Carriages.—A paper with this title was read at a recent meeting of the Hanover Elektrotechniker Verein by Dr. Büttner, of Hagen-i.-W., who, after touching upon the gradual development of the various systems in use, which may be divided into two groups—the lighting of the whole train from one or two carriages, and the independent lighting of each carriage by accumulators—described the electric lighting of the trains on the Danish State Railways in Seeland, of those on the Novara-Seregno line in Italy, the Jura-Simplon railway, and on the Dortmund-Gronau line, and of the Imperial German railway postal vans. He then drew comparisons between gas and electrical lighting unfavourable to the older illuminant. The disastrous effects of a railway collision had frequently, he remarked, been heightened by the gas setting fire to the carriages. The weight of the electric lighting apparatus, too, was much less than that of the gas apparatus of equal efficiency. The cost of electricity, moreover, compared favourably with that of gas. A gas plant for 170 carriages cost £2,500; an electric charging station of the same capacity £1,250. Dr. Büttner regretted, in conclusion, that 85 per cent. of German railway carriages are still lighted by gas.

Educating the Public.—Mr. S. V. Clirehugh, A.M.I.C.E., the consulting electrical engineer to the Corporation of Eccles, has delivered a lecture there in the Town Hall on "Electricity for Lighting, Heating, and Motive Power." Mr. Alderman Kendall, J.P., chairman of the Electric Lighting Committee, occupied the chair. The lecturer commenced by saying that he had to deal with the commercial side of the question, and that was what they had for the greater part come to listen to. If he were asked what electricity was he must candidly confess he did not know, but as to the generation and control of electricity these had come within the province of science. He enlarged upon the application of electricity as a motive power, and said that there was a great future in that direction. Coming to the question of cost, the established expense of the introduction was £1 a light, with all the necessary wires, and there was a company that would carry out the wiring on the hire-purchase system, so that a man who would say that he could not afford £10 or £20 to supply his shop, could do so by instalments. The lecturer proceeded to lay before the meeting his estimate of the cost of installation, etc., and deduced from the figures before them a saving to the consumer.

Telegraph Offices.—In the House of Commons, in answer to Mr. Henniker Heaton, Sir J. Hibbert said: "I cannot hold out any hope of an abolition of the guarantee system, but I would remind my hon. friend that much has been done of late years to encourage the extension of telegraphs in country districts. Rural sanitary authorities have been empowered to give guarantees for this purpose; the conditions of the guarantees have been very considerably lightened; and the Post Office is constantly making enquiries as to whether the business likely to be done at village post offices will justify the extension of the telegraph without any guarantee at all. The result has been that the number of country telegraph offices is increasing steadily and at a growing rate. In 1890-91 the increase was 275; in 1893-94 it was 673." Mr. A. Morley, also in reply to Mr. Heaton, said that there were about 500 telegraph offices in the metropolitan district, or, in other words, about one office to 10,000 people. Elsewhere there were about 9,150 offices, or one office to 3,600 people. The offices in the Metropolis had been established to meet the requirements of the public, and were only maintained if they paid their way To close any of them would not facilitate the establishment of telegraph offices in rural districts.

Electric Lighting in London.—On Monday Mr. Hazell, in the House of Commons, asked whether the Board of Trade had declined to grant orders in the Metropolis unless the power of purchase by the local authority was reserved at the end of 42 years from August 22, 1889, under the terms of sub-section 2 of the Act of 1888, and whether, as the period of 42 years was now reduced by nearly seven years and was daily diminishing, the President would consider the desirability of giving companies more favourable terms. Mr. Bryce said that was so; but Section 2 of the Electric Lighting Act, 1888, provided that the local authority might purchase the undertaking after the expiration of a period of 42 years or such shorter period as was specified in the provisional order. The Board of Trade had held that it was in the interest of London that the power of purchase by the local authority or authorities should as far as possible operate at the same date over the whole of the Metropolis. To this policy the Board of Trade adhered. The time did not seem to have arrived when it became necessary to consider whether any relaxations in the terms on which such undertakings may be purchased might require to be made in order to render it worth the while of companies to enter upon new enterprises.

English Companies in Spain.—Our Spanish contemporary *El Telegrafista Español y Revista General de Electricidad*—to give it its full title—has an article in a recent issue severely denouncing English telegraph and other companies whose sphere of operations lies wholly or partially in Spain or her dependencies. In one portion of the diatribe we are told that "English industrial companies continue to treat Spain as a conquered country." In another that "undoubtedly English companies consider us, from a telegraphic point of view, to be on the level of the African peoples, and

Digitized by Google

they consequently treat our country as a colony which they must exploit for their exclusive profit." And again, "the English, so careful in their own country to observe the law, seem to do their utmost to evade it when they establish themselves amongst us." These rambling observations are, it appears, induced mainly by alleged grievances against the Cuba Submarine Company and the Spanish Company upon questions of privilege, but there is a special grumble against one company that although, according to the terms of its contract, it was to substitute its English staff by Spanish employés in proportion as the latter became sufficiently competent, not a single Spaniard, the article affirms, has yet been found with the necessary aptitude. "Who," queries our contemporary somewhat bitterly, but we hope not altogether seriously, "who can drag an Englishman from a position where a penny is to be gained?"

Antiquity of the Incandescent Lamp.—One of the most interesting sights of New York is a performance at one of the Jewish theatres on the Bowery, there being several near Canal-street patronised exclusively by Russian Hebrews, in which the plays are produced in the Jewish-German-Russian jargon with a mediæval crudity. Each theatre has its own playwright, who, however, owing to the fondness of the audience for realistic scenes, has to divide the honours of the reproduction with the important personage who creates the realistic accessories. How important the functions of the latter are, says the *Electrical World*, will be evident from the following description of a scene from a play entitled "Jonah," produced at the Old Bowery Theatre. "After Jonah has been thrown overboard, for a moment," says the reporter, "it appears that nothing can save him. But just as he is sinking for the last time a great fish comes along, shaped something like a flounder, and deporting itself like a ball of rubber; it opens a very wide mouth and Jonah climbs in. Instantly the ship, which has been hammering the stage boards in its wild tossing, becomes still. The ballet sailors on the deck set up a jubilant chorus, and a gauze-dressed angel drops down from the flies, while the fish—which has disappeared behind the scenes—turns about and re-enters with a new side presented to the audience. This new side is as open as the day. Through an oval window in the whale's larboard quarter Jonah is disclosed sitting in great splendour of red and green, with glow lamps, and not a suggestion of discomfort." The anachronism of the incandescent lamp probably did not appeal to the enthusiastic audience.

London Chamber of Commerce.—The thirteenth annual general meeting of the London Chamber of Commerce was held on Tuesday afternoon in the council-room, Botolph House, Eastcheap—Sir Albert K. Rollit, president, in the chair. The report showed that the work of 1894 had produced more important results than that of any previous year. The financial record was satisfactory, a balance of £534 having been carried forward, while there had been an increase of 360 members during the year, and the number of meetings had risen from 280 in 1893 to 334 during the past 12 months. The report and accounts having been duly adopted, on the motion of the chairman, seconded by Mr. W. H. Willans, the following gentlemen were added to the council: Colonel G. R. Birt, Mr. T. F. Blackwell, Sir E. H. Carbutt, Mr. J. Colman, jun., Mr. E. J. Gillespie, Mr. G. N. Hooper, Mr. J. J. Jackson, Mr. G. S. Mackenzie, Sir Samuel Montague, M.P., Mr B. S. Odling, Mr. R. H. Pringle, and Mr. A. Serena, being proposed by Sir G. Baden-Powell, M.P., and seconded by Mr. McAllister. Sir Albert Rollit was unanimously re-elected president, and Mr. J. Chambers and Mr. S. B. Boulton vice-presidents for the ensuing year. Lord Brassey, Sir G. Baden-Powell, M.P., Sir Douglas Fox, Major-General Sir F. R. Pollock, and Sir F. Dixon-Hartland, M.P., were elected members of the council of reference. Sir A. Rollit delivered an exhaustive address on the progress of British trade, and argued that his conclusion was that after a long period of depression, which had been wonderfully well borne by the great majority of the working classes, there were indications of an improvement, if we would learn lessons, partly from our foreign competitors.

Curious Procedure.—The *Times* says: "We have received from a correspondent, who states that he is not a shareholder or in any way interested in the National Telephone Company, but is simply a customer of it, a copy of a printed circular addressed to him by Mr. de la Hooke, the clerk of the London County Council. It cannot be considered a dignified course for a public body like the Council, who are trying to buy the telephones of London, to send round to all telephone users, with a view of depreciating the property, such a circular (stamped for reply) touting for complaints. The circular states that a select committee on telephone service has been appointed "to consider and report whether the provision now made for the telephone service in' London and other 'areas is adequate, and whether it is expedient to supplement or improve this provision either by the granting of licenses to local authorities or otherwise.' The Highways Committee of the London County Council, to whom the duty of procuring evidence on this matter is referred, being of opinion that telephone service in the Metropolis should be rendered cheaper and more efficient, have submitted their views to this effect to the Select Committee, and similar evidence has been tendered by the Commissioners of Sewers of the City of London. The committee of the Council are anxious to know accurately what is the opinion of the users of telephones in London as regards efficiency, and answers are requested to the following questions—'(*a*) Is the existing telephone service of the National Telephone Company efficient and satisfactory to you? (*b*) If it is not satisfactory, in what respects is it unsatisfactory? (*c*) What suggestions (if any) would you make for the improvement of the service?'" It will be noticed that the Commissioners of Sewers have adopted a similar course.

Products of Combustion of the Electric Arc.—This is the title of an article by M. N. Gréhant in *Comptes Rendus*, p. 815. The author remarks that among the gases liberated from carbons kept incandescent by the electric arc is carbonic oxide. His method of operating was as follows: Around a lamp, the carbons of which gave a powerful and constant light, was arranged a small wooden box, 43cm. long, 29cm. wide, 60cm. in height, and of a capacity of 75 litres. Two metal tubes were fixed on two opposite sides, one at 2cm., the other at 32cm. from the bottom of the box, which was almost completely closed by a lid traversed by the cylindrical body of the electric lamp. Three experiments were made. They consisted in causing a dog to breathe for half an hour the gases resulting from the combustion of the carbons combined with the exterior air drawn in by the respiratory movements through hydraulic valves. The inspiration took place in the box, the expiration outside. The arterial blood of the dog, taken in the carotid artery, was analysed before and after each experiment. In the first, the dog was placed in the box after the lamp had been running half an hour. The analysis gave $\frac{1}{1400}$ as the proportion of carbonic oxide contained in the air breathed by the animal. In the second, the dog was put in the box at the moment of lighting the arc. The proportion of carbonic oxide was then $\frac{1}{3000}$, the reduced

Digitized by Google

quantity being due to the gas not having been able to accumulate in the box. The treatment of carbonic anhydride by barytes water contained in a tube placed between the electric arc and the exhaust-valve gave $\frac{1}{87}$ for the proportion of this gas, or 53 times greater than that of the oxide of carbon. The third experiment, made under the same conditions with another dog, gave $\frac{1}{2500}$ as the proportion of carbonic oxide, and $\frac{1}{62}$ as that of carbonic anhydride. M. Gréhant thus concludes his article: "It is, therefore, certain that the carbons of the electric arc throw off carbonic oxide in small quantities. If the lamps are in rooms of small size, such as certain of those containing machines generating electricity, the liberation of the toxic gas in the close atmosphere may contribute to produce among the workers the serious maladies which have from time to time been reported. A thorough system of ventilation should consequently be established, which would carry away all the products of combustion."

Electric Lighting of Cars.—The lighting of the cars of a cable road by electricity is a novelty, and requires the use of some special apparatus. In the main, the plan adopted on the Brooklyn Bridge, New York, says the *Scientific American*, resembles the now familiar trolley system. A bare copper wire is suspended from poles and from the framework of the bridge. This wire is carefully insulated, the return is made through the rails in the usual way. The current is supplied from the power-house in Brooklyn. It is led to the centre of the bridge through a feeding cable, which there divides into two branches, one leading to each of the towers and there connecting with the overhead wire. The overhead wires are in turn connected together at intervals of 500ft. The height of the wire above the car was regulated by the framework, which extends over the three suspension spans. The distance that this framework clears the car only allowed the wire to be suspended 9in. above the roof of the car. At first it was thought that a regular trolley with a short pole could be used, but the rocking and swaying of the cars was so great in proportion to the distance of the car from the wire that it had to be abandoned. Springs were used to allow the trolley a certain amount of play, but this was not enough to keep the wheel on the wire. A roller was then substituted for the wheel. This roller is made 18in. long, and is mounted in two arms, with which the roller forms a triangle, the apex being attached to the hinge and spring. The length of the roller is really greater than is necessary, but it allows a safe margin, and there is very little chance of it ever jumping the wire. In the daytime the roller is lowered to avoid unnecessary friction. When the lamps are to be lighted, the trainman of each car pulls a lever at one end of the car which operates bell cranks and a connecting-rod, which raises the roller into contact with the wire. It has been found advantageous to have the roller trail, no matter in which direction the car may be going. On the Brooklyn Bridge the lighting trolley or roller is tripped and reversed automatically in the stations while the cars are being switched, by means of a rigid frame. The cars are all connected by wires, so that if the trolleys on all the cars but one should get out of order, that one would be sufficient to light the train. When the cars are being switched this system prevents the flickering of the lights. As in the bridge itself, there is a slip or expansion joint in three places to allow for the expansion and contraction caused by changes of temperature. Great care is taken to maintain an even tension on the line.

Telephones and Thunderstorms. — Our contemporary the *Lancet* having fortunately no gas-*cum*-electricity explosions, nor reports thereon, to comment upon, has now struck out in a new line under the heading of telephones and thunderstorms. It says: "It is to be remembered that an overhead telephone wire becomes in point of fact a lightning conductor, and in this capacity may act in two ways: (1) by equalising differences of potential it may prevent the occurrence of the disruptive charge; or (2) receiving a lightning charge it may carry the current to earth. With reference to the first point, there can be little doubt that overhead conductors if connected to earth do play an important part in the distribution of atmospheric electricity. Lord Kelvin in a recent paper (read before the Philosophical Society of Glasgow) states that the difference of potential he obtained between the earth and an insulated burning match placed 9ft. above the ground was 200 to 4,000 volts. What, then, is the result of permanently connecting by a good conductor the earth and the atmosphere directly above it, a condition which exists in the case of single-wire telephone circuits? Such an arrangement must tend to equalise potential and prevent the accumulation of those charged masses which no doubt form the nucleus of the storm cloud. This equalisation will continue to take place in all conditions of weather. But when a storm does occur it is obvious that if struck by lightning the wire carries the current to the point of greatest danger—viz., to the instrument and to anyone in its vicinity. Therefore, unless the strictest structural precautions be taken, such a wire becomes a source of danger rather than of safety. To obviate this danger, every post or support for overhead wires ought to be fitted with a lightning guard, and every instrument, whether using the earth as a return or not, should be fitted with an efficient form of lightning arrester. Where the overhead wires are not connected to earth, as is the case with overhead lighting mains and twin telephone circuits, any equalising effect upon potential difference is practically lost, and any circuit connected with overhead wires must be dangerous, inasmuch as such wires become lightning conductors in all but the saving device of an earth connection. For lighting mains it can scarcely be doubted that the underground system is in most respects the better: (1) for obvious reasons connected with the size of the cables; (2) for the electrical reason that if carried overhead no earth connection is allowable, by the rules of the Board of Trade. For telephones the adoption of the twin-wire system seems to bring with it the advisability of placing the wires below the surface of the ground, inasmuch as this system does away with the earth return as part of the circuit. It therefore appears that from an electrical point of view there may be in overhead wires an element both of safety and of danger. The latter will certainly predominate unless supports be protected with lightning guards and every instrument provided with an efficient protector—that is, with an unfailing means of carrying a strong current to earth without passing through the instrument. Is this secured in practice? Can it be secured with any certainty by even the best lightning arrester or earthing device of any descripton? So long as the coarse expedient of a connecting wire is necessary for the guidance of electrical energy, so long must this question of wiring, with its safeties and its dangers, be one of great and growing interest. But it may be pointed out that if every house were fitted with an efficient form of lightning guard a greater immunity from lightning discharges would be secured than that which at present exists with the closest network of overhead telephone wires." This subject is even more remote from what one would expect in a medical paper than were the previous articles on explosions.

ELECTRIC LIGHTING OF TRAINS.—II.

BY R. W. WEEKES, WHIT.SCH., A.M I.C.E

(Continued from page 445.)

There have been many engineers at work in England on the subject of the electric lighting of trains, and a brief historical *résumé* will be of interest before commencing to describe those systems which have survived the test of everyday work. Some of those systems which have dropped out of the running have been hardly dealt with, as extraneous reasons—such as insufficient power in the locomotive boiler, etc.—have led to their being discontinued. Also, there has always been the disadvantage felt by young competitors trying to establish a business on ground already occupied. In the present case there has been felt a want of interchangeability between portions of the electrically-lighted trains and other carriages otherwise lighted.

There have been several papers read on this subject before different engineering institutions which are now historical, and which are well worth reading by anyone interested. The first of these was read by Mr. W. H. Massey before the Society of Telegraph Engineers and Electricians in March, 1884, and was called "Notes on a Train-lighting Experiment." The discussion following on this paper is most interesting reading, many of the speakers being still the leaders in all discussions at the now "Institution of Electrical Engineers." The next paper of interest is one by the late Mr. W. Stroudley, M.I.C.E., read before the Institution of Civil Engineers in 1886. Then in May, 1891, Mr. W. Langdon read a paper before the same institution on "Railway Train Lighting."

The first recorded attempt made in England to light a part of a train electrically was in October, 1881, when the London, Brighton, and South Coast Railway fitted a Pullman car with accumulators. The car thus lighted was employed in regular traffic between Brighton and London. The cells were charged during the night at Victoria. In 1881, Mr. Alexander Siemens lighted up a train on the North of Scotland Railway, using a Brotherhood engine coupled to a D 3 Siemens dynamo placed on the engine. Some 30 Swan lamps were placed in the train, but the directors of the railway would not proceed with the scheme on account of cost. In 1883-4, a novel experiment was tried by Mr. W. H. Preece on the London and South-Western Railway. Mr. Preece's idea was to employ the movement of the train to compress air into a chamber, and to use the air so compressed to drive a dynamo by means of a compressed-air engine. The air was compressed to 500lb. per square inch by means of an air-pump driven from the axle of the guard's van. Although to a large extent successful, the experiment was finally abandoned. About this date the late Mr. W. Stroudley commenced to investigate the subject in conjunction with Mr. E. J. Houghton. In December, 1893, the first train lighted by them commenced running on the London, Brighton, and South Coast Railway. In the first 11 months it made 2,352 trips, covering some 27,500 miles. The number of trains was gradually increased, various improvements being made. In 1886 this company had three trains fitted with dynamos driven off the axles of guards' vans and used in conjunction with accumulators to light the trains. At the present time the number of trains so lighted has increased to 40. In August, 1884, the London and North-Western Railway applied the electric light to a short train travelling between Manchester and Liverpool. The equipment consisted of a dynamo coupled to a Brotherhood engine supplied with steam from the locomotive boiler. It was placed in an iron compartment behind the tender, and hence was under the control of the engine-driver. The lamps were connected direct on to two wires led from the dynamo throughout the length of the train, and no accumulators were used.

In November, 1884, Mr. W. H. Massey fitted up a train with electric light for the Metropolitan District Railway. This plant, which was successfully run for two months, is of great historical value. I am assured by Mr. Crompton that the first Willans central-valve single-acting engine made was employed to drive a Siemens dynamo in this attempt to induce railway engineers to take the matter up. The engine and dynamo are shown in Fig. 2. Mr. Massey found that by evaporating 211lb. of water into steam at a pressure of 120lb. per square inch, it is possible to keep 50 lamps, of 16 to 18 candles each, going for one hour. He also stated that as the efficiency of the dynamo used was rather low, on account of the reduced speed of driving, it is probable that slightly better results might be obtained in cases where the machinery is more perfectly adapted to the work. Taking matters as they were, however, 4½ h.p. was used in the lamps and leads, over 30 per cent. of the brake horse-power of the engine was wasted in the dynamo, and nearly 15 per cent. of the gross power was lost in engine friction, so that the indicated horse-power of the engine (7·175) was obtained for about 30lb. of water per indicated horse-power hour, which is a fairly economical performance. The contractors made a trial of the same engine and found the consumption of water to be only 28lb. per indicated horse-power hour, but Mr. Massey was not present at that particular trial. The complete plant in the guard's van consisted of an engine, a dynamo, a launch boiler, water-tanks, and coal-boxes, so that the cost of supply could be accurately found. Fifty-two Swan lamps of 18 c.p. (20 c.p. nominal) were used, and it was deduced that the working expenses of the electric light would be as follows if steam could be taken from the locomotive boiler:

	s.	d.
Coal, per thousand lamp hours.....	3	9
Water „ „	0	3
Oil and waste „	1	3
Lamp renewals „	2	6
In all	7	9

to which must be added interest on capital, and charges for depreciation and repairs. The first cost of fitting up a train

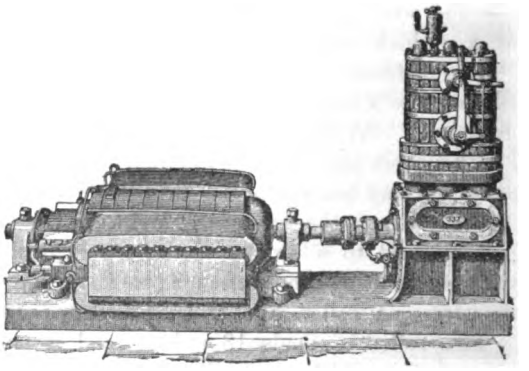

FIG. 2.—The first Willans Central-Valve Engine, as used with Siemens Dynamo for Train-Lighting in 1881.

with 50 lamps and suitable machinery, etc., would be about £170. It will be seen that no labour was charged, but assuming that this, with repairs, brought the total up to 15s., the cost per candle-power hour would only be $\frac{180}{1{,}000 \times 18}$ d. = ·01 pence.

At the end of 1885 Mr. Crompton commenced to supply some train-lighting sets to the Great Eastern Railway. A Crompton dynamo, coupled to a Tower spherical engine, was placed on the boiler just behind the steam-dome. Seven trains were eventually lighted direct in this way, but it was found that the locomotive boilers had only just sufficient steaming capabilities to supply their own engines. The Tower engines, although fairly economical at first, took a large amount of steam when the packing on the spherical surface began to wear. These causes led to the abandonment of electric lighting on that line.

In July, 1886, the Great Northern Railway Company applied the electric light to one of their metropolitan trains, and subsequently several more have been fitted, until at the present time this line has some 10 electrically-lighted trains running; these are always coupled and never broken up. In this case, also, the energy is taken from the axle of the van. In 1889, Mr. W. Langdon again took up the question of electric lighting of trains. In the early days he had

Digitized by Google

attempted to light a train from primary batteries, but, as will be seen from the discussion on Mr. Massey's paper, the impracticability of this method was soon found out. In the new attempt, Mr. Langdon used the apparatus for obtaining constant potential from a dynamo driven from the axle of the guard's van, which will be described in following articles. The express trains in which it was used had to be broken up frequently, and hence accumulators were placed in nearly every carriage. Other recent systems will be described, including that used by the Railway Automatic Electric Light Syndicate on the underground railways in London.

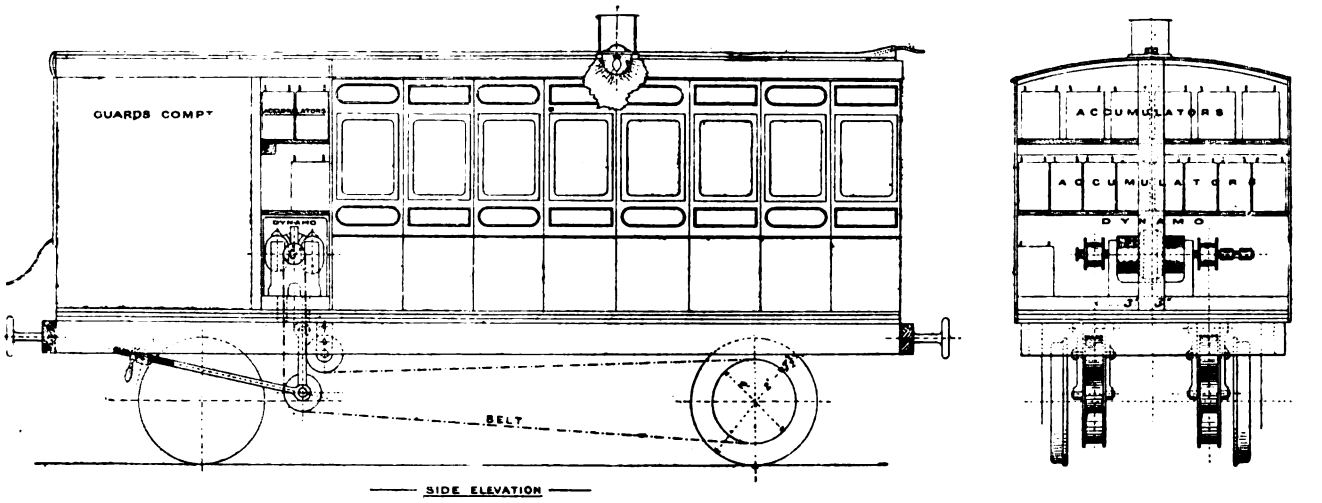

FIG. 3.—Elevation and Section of L. B. and S. C. Railway Guard's Van, showing method of Tightening Belts and arrangement of Plant.

I propose to describe the various arrangements for the lighting of trains electrically in England in order. The length of time in which each has been at work will determine the sequence.

LONDON, BRIGHTON, AND SOUTH COAST RAILWAY.

The electric lighting arrangements used on this company's lines have been designed and improved by the late Mr. W. Stroudley and Mr. E. J. Houghton. The dynamo is placed in the guard's compartment, and the accumulators are either distributed over the whole of the train—a certain number in each coach—or they are all put in the same vehicle as the dynamo. In the former case, each carriage carries its own supply of electricity; whilst in the latter, it is concentrated in the carriage containing the dynamo, and the trains so fitted are never uncoupled. For local services this is no drawback, as it is a great advantage to have the accumulators of a large type, and all in one place. Brush 5 L dynamos, capable of giving 55 amperes at 70 volts, are employed. They are furnished with a pulley at each end. Link leather belts, 4in. wide by 34ft., are led from the far axle of the carriage over jockey pulleys to the dynamo, Fig. 3. The tension of the belt is adjusted by one of the pulleys. As soon as the train moves the dynamo armature rotates. Attached to the dynamo

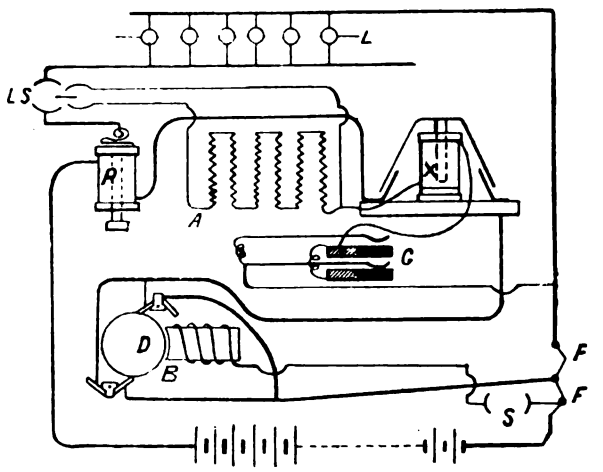

FIG. 4.—Diagram of Connection in L. B. and S. C. Railway Guard's Van.

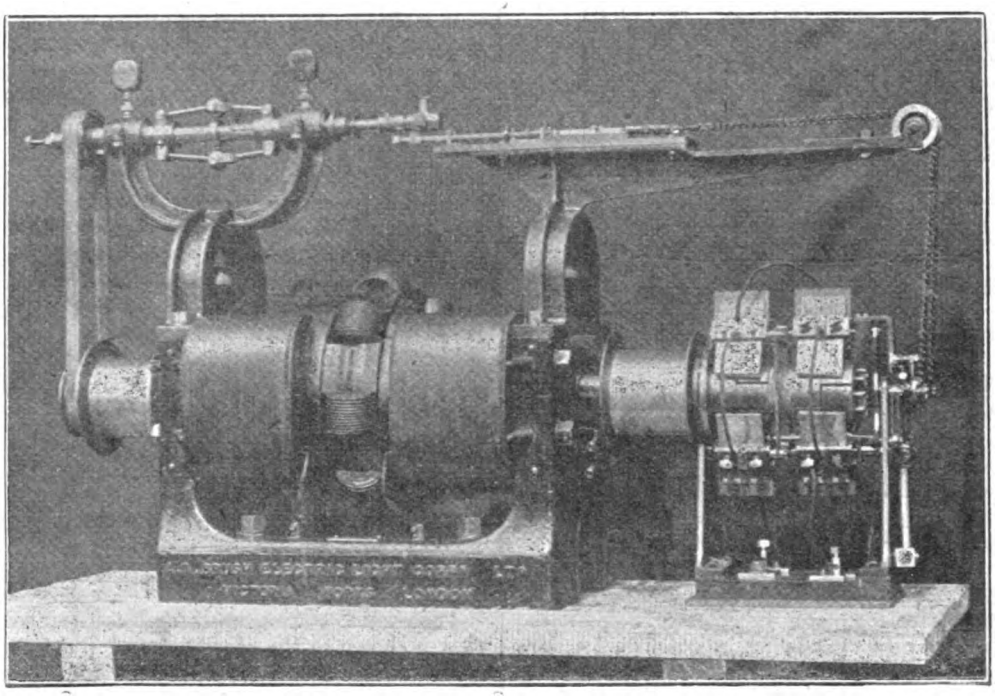

FIG. 5.—L. B. and S. C. Generating Gear, showing Governor and the Double Set of Brushes.

Digitized by Google

by means of a small strap, is a centrifugal governor, which automatically controls the brush gear. When the train attains any prearranged speed—say, eight miles per hour—the governor closes a relay through an electromagnet, X, (Fig. 4), thereby putting the accumulators into the dynamo circuit, and causing the dynamo to charge them. As the speed of the train increases, the E.M.F. and the current of the dynamo rise—the governor gradually draws the brushes forward so as to prevent sparking at the commutator. As the speed of the train diminishes the reverse operation takes place, the brushes gradually returning towards their original position, until at the eight miles per hour the governor breaks contact, and the dynamo ceases to charge. The dynamo is fitted with double sets of brushes, as will be readily seen from Fig. 5. One set is used for each direction of rotation corresponding to the two different directions in which the train may travel.

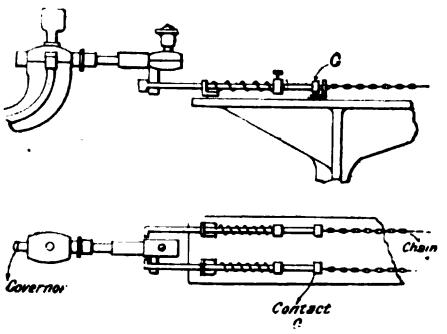

FIG. 6.—Details of Governing Gear.

The direction of rotation of the governor determines which of the sets shall be used in the manner shown in Fig. 6. One rod is used to control by means of a chain each of the sets of brushes. Each of these two rods has a similar relay contact, as shown in G, Fig. 4, and is moved to-and-fro over a considerable range by the governor, the position of the rod at any time depending only on the speed of the train. The extension of the governor spindle carries a mandrel free to rotate in it, but prevented by a wing plate, seen in Fig. 6. This mandrel is turned by friction when the train starts till the wing plate comes against either one or the other of the rods with which it engages.

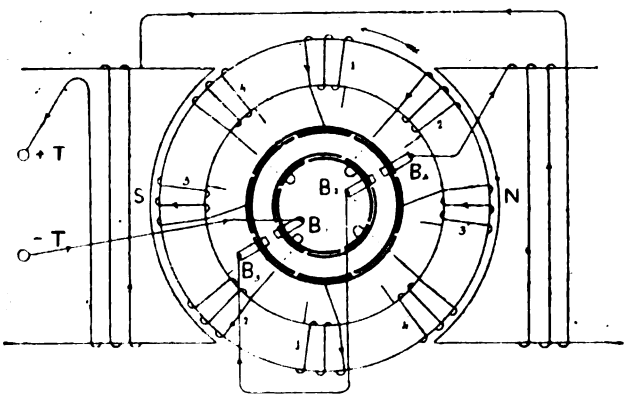

FIG. 7.—Diagram of Connection in the Brush Armature.

Any increase of speed then causes the governor balls to fly out, and the rod is drawn back by the force thus obtained, until, firstly, the brushes are put on to the commutator, and then by the relay the charging circuit is closed. Placed in the dynamo circuit there is a regulator, consisting of a solenoid with an iron core, R (Fig. 4), to which is attached some German-silver wire made in the form of a bed spring. This resistance is in the lamp circuit, and acts in such a manner that as the current in the dynamo circuit varies, more or less resistance is automatically inserted in or removed from the lamp circuit by the spring being gradually lifted up from or lowered on to the conducting plate. In this way the potential of the lamps is maintained as constant as possible. (A wire connection between A and B in Fig. 4 has been accidentally omitted.) Twenty-three of the 19 L accumulators of the Electric Power Storage Company are used in each of the uncoupled trains. The accumulator plates last about two and three-quarter years on the average, but have to be dismantled every 16 months and thoroughly cleaned. They have a capacity of some 350 ampere-hours. Lately, some of the K type have been used for renewals. Thirty-eight lamps of 16 c.p. are used per train, and they last about six months.

Through the kindness of Mr. E. J. Houghton, I was allowed to inspect this gear in work under the able guidance of Mr. W. Payne. The first point that strikes the casual observer is the fact that the E.M.F. of the dynamo rises so little with the increase of speed, although no regulator is used in the exciting circuit. This is the peculiar feature of the Brush open-coil armature, and is due to the great armature reaction found in these machines. Another way of stating concisely the same fact is to say that the self-induction of the coil is so arranged that it is impossible to obtain more than a certain current out on account of the back E.M.F. induced. Many argue that these two effects are both present, but I have found from experience on alternators that in armature cores carrying fluctuating currents the two effects are synonymous. In this case the speed of the alternator when working on the accumulators varies from 500 up to 2,000, and yet the voltage at the terminals does not vary more than about 10 volts. The only trouble found with the automatic gear is that common to almost all mechanical contrivances of the same nature. The friction of the brush rocker and the governor gear makes it difficult to regulate exactly for both ascending and descending speeds. In this way, if the governor puts the brushes on at exactly the right moment, it is liable, due to the lag caused by friction, to delay taking them off till after the speed has fallen slightly below the right value.

In some older arrangements of plant still in daily use electromagnets are used to put the brushes on at the right moment, and at the same time to connect the circuits. In this case the lead of the brushes is not varied with the speed, but it is found that the wear due to a little sparking from this cause is not excessive. In fact, the brushes last as long as those on the plant described above. The oiling arrangements have been most carefully considered. Ring lubrication is used, and any deficiency of oil due to waste is made up from an inverted bottle, the nipple of which is supported in the oil-chamber at the correct level for the oil. In this way the machinery often runs a fortnight without additional oil.

Mr. E. J. Houghton has kindly furnished the following figures as to the cost of lighting the train under his charge: The trains cost about £400 each to equip, and the working cost for maintenance and renewals for the 12 months ended December 31, 1894, was £54 per train. There are now in use 36 suburban block trains of 10 to 12 coaches each, and four main-line fast trains equipped with this system, or a total of 410 coaches, including Pullman cars. Experience has proved that these trains are more serviceable than gas-lighted trains, being always ready to run, and to run continuously. They do not need haulage to charging stations or to be left at any particular depôt. It is estimated that the company gets about 15 per cent. more work out of them than from gas-lighted trains, so that if, for the purpose of this comparison, we take the cost of building a 10-coach train at £3,000, there would be a saving of about £45,000 in the construction of 100 trains—*i.e.*, 85 electrically-lighted trains would do the work of 100 gas-lighted trains. Mr. Houghton finds that the cost of upkeep decreases considerably with the number of trains fitted.

The London, Brighton, and South Coast Railway are to be congratulated on the success of their engineers in their dogged efforts to perfect the lighting systems on their trains.

ELECTRIC LIGHTING IN THE FAR EAST.

AN ALTERNATING STATION AT HONG-KONG.

The central station at Hong-Kong (of which an interior view is shown in the accompanying illustration, Fig. 1) has now been in successful operation for 5½ years, it having been installed and the public lighting started in December, 1890. It was designed by J. W. Hart, Esq., M.I.C.E., of 39, Victoria-street, Westminster, S.W., for the Hong-Kong Electric Company, Limited, and the whole of the plant,

Digitized by Google

including engines, boilers, dynamos, motors, switchboards, lamps (arc and incandescent), mains, columns, etc., was supplied by Messrs. Johnson and Phillips, of Charlton, Kent.

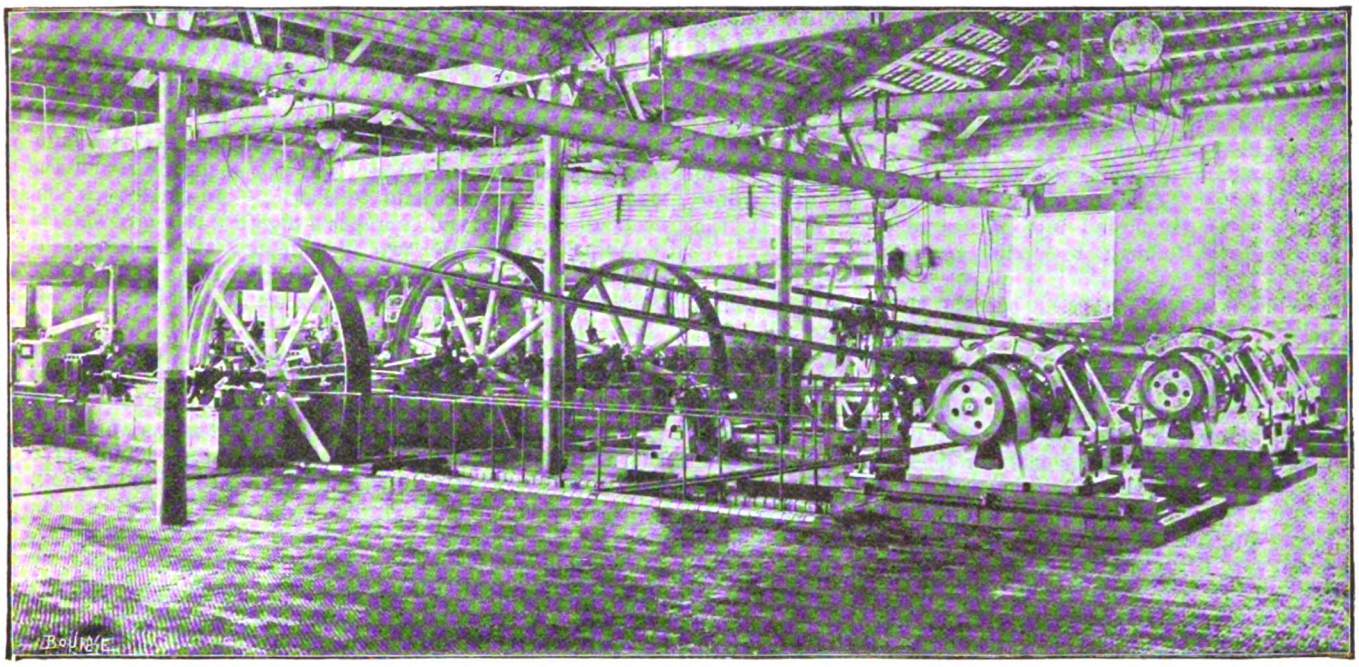

FIG. 1.—Interior of the Hong-Kong Electric Lighting Station.

off in two steps or terraces, on the upper of which the engine-room is built, and on the lower the boiler-house, stores, and offices. The engine-room is about 100ft. long by 75ft. wide, and contains five horizontal compound

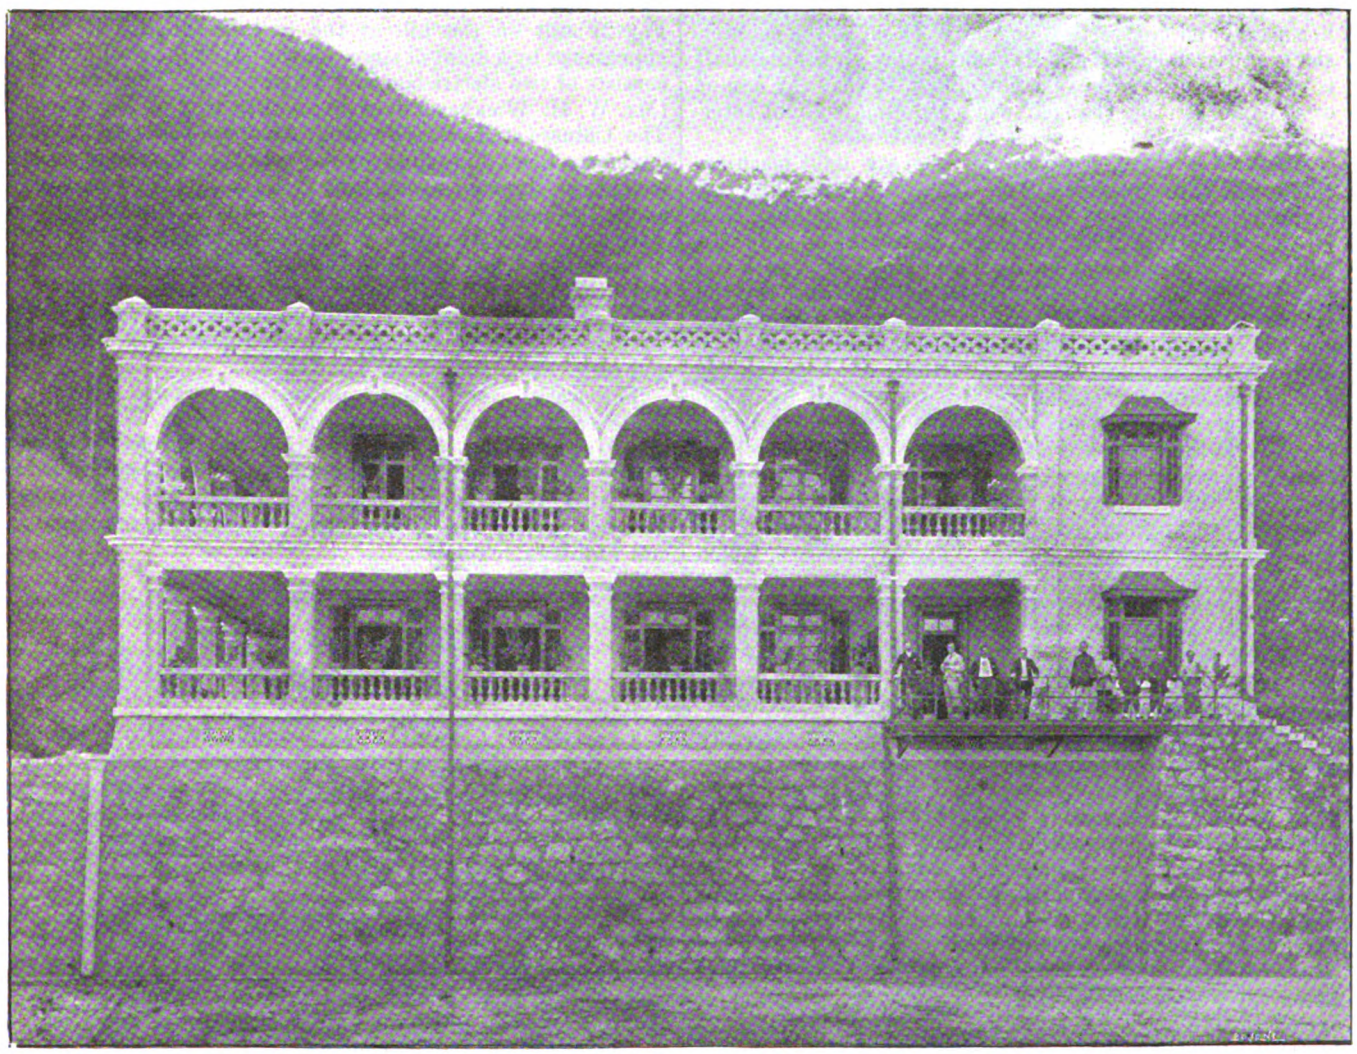

FIG. 2.—The House provided for the Staff of the Hong-Kong Electric Lighting Station

The station is situated at the east end of the town of Victoria, Hong-Kong, in the Wanchai district. It is built on the side of the hill, just below the aqueduct which supplies Hong-Kong with water, the ground having been cut engines of 90 nominal horse-power, with jet condenser at back of low-pressure cylinder. The engines run at 100 revolutions per minute. The flywheel, which is between the high and low pressure engine, is 13ft. in

Digitized by Google

diameter, with six grooves on the face for driving ropes 1¼in. diameter, leading direct to the countershaft for driving the dynamos. There are two patent feed-water heaters. The water supply for the condensers is obtained from a tank about 75ft. by 50ft. by 8ft. dug out of the hill at the back of the engine-room, and fed by a small stream from the hills. The boilers are also supplied from this tank, but during the dry season from the town supply. The cold water from the hills run in at the bottom of the tank, and the supply to the condensers is also taken from the bottom. The water after being used for condensing purposes is discharged into the same tank, but at the surface level, to facilitate cooling, and is used again.

The boiler-house, which is on the lower level, is reached by a flight of stone steps. It contains three steel Lancashire boilers with Galloway tubes. The boilers are 26ft. 6in. long, and are worked at a pressure of 140lb. to the square inch. They are supplied with water both by injectors and two donkey pumps. As a rule only one boiler is in use, but a second is kept under steam in case of accidents. There is a large space for coal storage alongside the boilers. The flue which passes along the back of the boilers passes through the wall and into the chimney shaft, which is 75ft. high. Japanese coal is used, and although rather smoky gives very little trouble in keeping steam. Next to the boiler-house is a store for cables and line materials, and there is also another large store fitted up with shelves all round, and having a gallery round it for the storage of electric light fittings and glass. There is a small office fitted up for testing and for regulating and testing the meters for the house supply. The alternating meters are of the shunt type. The three arc light dynamos, which are fitted with automatic regulators, are each of 55 lights capacity, and are run off a countershaft by belts. Two horizontal and one vertical engine work on to the countershaft, and each engine and dynamo pulley on countershaft is controlled by a patent friction clutch, so that any engine or dynamo can be changed while running without interrupting the lights in the event of a breakdown.

There is a spare armature for the arc light machines which will fit any machine. The alternators are 50-kilowatt Kapp type running at 650 revolutions per minute, with 75 ⁀⁀ and giving 2,000 volts, and are placed on slide rails with shifting screws, and bolted down to solid brickwork and granite foundations. The arc light dynamos are laid on baulks of timber bolted down to brickwork foundations, and the machines are surrounded by a wooden platform on oil insulators to guard against the danger of shocks to the dynamo attendant. The alternators are excited by Kapp dynamos giving 50 amperes and 150 volts, which are driven by belts off the alternator shafts. An overhead travelling crane runs across the engine-room for handling the heavy parts of the machinery. Johnson and Phillips transformers, transforming from 2,000 to 100 volts, are used in the houses for private lighting. The switchboard, which is at the back of the engine-room, is of teak and is about 3ft. away from the wall, thus allowing access for connecting up the leads. All the instruments are mounted on enamelled slate slabs, arranged one for switch gear for the alternating circuits, two for fuses for the same, one exciter circuit board, and one one-light circuit board.

Lightning arresters of the magnetic air-gap type are placed on each pole of every circuit leaving the switchboard to protect the dynamos and instruments. These were adapted in preference to the brush type, which did not answer in the severe storms which Hong-Kong is subject to, and it was no uncommon thing to have the arc circuits struck and short-circuited 20 or 30 times in an hour during a heavy storm. Sometimes it was impossible to keep the incandescent circuits going, as the fuses were blown as fast as they were replaced owing to the lines being repeatedly struck. However, after the adoption of magnetic arresters in the station and Wurtz arresters at intervals along the lines there were seldom any mishaps. In front of the switchboard is a platform laid with rubber mats and guarded by a rail to guard against accidents from shocks. Each arc light machine has also a patent regulator on the switchboard.

The principal streets are lit by 80 double-clutch non-focussing Brockie-Pell arc lamps. These are fixed in carriers with a reflecting hood, and placed on top of iron lattice poles 40ft. high, except in a few cases, where shorter poles were found necessary. These posts carry wrought-iron brackets, on which are fixed insulators to carry the cables both for the arc lamps and incandescent circuits. Wrought-iron taper poles, with cast-iron bases, are also used for carrying the leads. Johnson and Phillips patent fluid insulators are used for carrying the stranded steel bearers. The cables, which are $^{7}/_{16}$ stranded wire, are high-insulation vulcanised rubber, and are suspended from the steel bearers by porcelain insulators. An earth wire connects all the posts and lamp-posts together to guard against lightning. There are two incandescent and two arc light circuits. The Government House, the Hong-Kong Club, the principal banks, and residences are lit with incandescent light—in all about 10,000 lamps.

In spite of the fact that the overhead wires have on several occasions been damaged by fire and blown down by typhoons, there is no doubt that the company were well advised in adopting the overhead system, as the other alternative of putting the wires underground would have been exceedingly costly, owing to the nature of the ground, which is nearly all solid granite. As it was, many of the holes for the posts had to be blasted out with gunpowder. In connection with the troubles with typhoons, it may be interesting to mention that on one occasion some Chinese junks were blown right up against the sea-wall, and their masts, becoming entangled with the cables which ran alongside, brought them to the ground, together with some dozen posts which carried them. Strange to say, no interruption occurred to the lighting—thanks to the good insulation of the cables—and the station officials were not even aware of the accident until the following morning.

There is a handsome house (shown in the illustration, Fig. 2) built on the hill at the back of the station, and approached by a flight of steps, for the use of the staff, which consists of two electricians and an engineer. The manager (Mr. W. H. Wickham) lives in another part of the town. The Chinese staff comprise about 24, there being two head engineers, one taking duty by day and the other by night; also fitters, dynamo attendants, greasers and stokers, and about 10 linesmen for outside work and for house wiring. There are two Portuguese foremen for superintending the house wiring. The Chinese staff are very intelligent, and soon learn the work and make very good wiremen. The company, being the only electrical engineers in Hong-Kong, have done a lot of ship-lighting and repair work for mail and cargo boats entering the harbour.

The works were erected under the personal superintendence of the present manager (Mr. W. H. Wickham), and have given the most satisfactory and efficient results during the whole period from date of incorporation in December, 1890. In the work of installation Mr. Wickham was seconded by Mr. G. Sanderson, one of Messrs. Johnson and Phillips's engineers.

ELECTRIC MAINS IN PARIS.

BY A. MONMERQUE.

(Continued from page 421.)

In three preceding articles the systems of mains have been described which experience in Paris has gradually condemned—namely, (1) the use of metallic conduits, with covered cables, and without any special precautions in the question of support; (2) earthenware channels; (3) covered cables on iron hooks.

Recent explosions in London confirm what has been said on the subject of metallic conduits. In the interest of the development of electrical industry, it is important to exercise the most minute care in laying mains to guard against accidents, which may in a large town have very grave consequences and throw undeserved discredit on the electric lighting industry in general.

There are at present in Paris only three systems of mains: (1) bare cables in cement conduits, called *caniveaux*; (2) covered cables in underground conduits either of cement or metal; (3) armoured cables.

From the point of view of future development, the last-

Digitized by Google

named system excels the others. Some mains at first laid with naked cables have been replaced by armoured cables.

The general situation of the mains in Paris on January 1, 1895, is set forth briefly in the following tables, where the districts are indicated by letters. The lengths given are those of the mains—that is to say, half of the length of the conductors in a two-wire distribution, a third in a three-wire distribution, etc. In the conduit system there are often in the same conduit both feeders and distributors. Then the lengths of conduits with feeders and distributors are separately detailed.

TABLE I.—Bare Cables in Concrete Cement Conduit.

—	Feeders.	Distributors.	Total.
	Yards.	Yards.	Yards.
District A[1]	17,200	51,000	68,200
District B[2]	18,900	36,200	55,100
Total	36,100	87,200	123,300

Observations.—[1] Two-wire distribution in concrete conduits. [2] Three-wire distribution.

TABLE II.—Covered Cables in Conduits.

—	Feeders.	Distributors.	Total.
	Yards.	Yards.	Yards.
District A[1]	765	2,630[2]	3,395
District B[2]	—	15,500[4]	15,500
District C[5]	2,950	2,400[6] + 3,720[7]	9,070
Total	3,715	24,250	27,965

Observations.—[1] Two-wire distribution. [2] Three-wire distribution. [3] Five-wire distribution. [4] In metallic conduits in paraffined wooden cases. [5] Two and three wire distribution. [6] Covered cables on porcelain insulators. [7] Covered cables placed in wooden casings and in concrete conduits.

TABLE III.—Armoured Cables.

—	Feeders.	Distributors.	Total.
	Yards.	Yards.	Yards.
District A[1]	186	219	405
District B[2]	—	1,095	1,095
District C[3]	328	109	437
District D	5,250[3] + 1,860[2]	24,700[3] + 7,000[2]	29,950[3] + 8,860[2]
District E[3]	22,500	54,600	77,100
District F[4]	13,900	52,200	66,100
Total	44,024	139,923	183,947

Observations.—[1] Two-wire distribution. [2] Three-wire distribution. [3] Five-wire distribution. [4] Two-wire distribution (concentric cables).

TABLE IV.—Recapitulation.

System.	Total length of conductors.	Proportional percentage.
	Yards.	
Bare cables in underground conduits	123,000	37
Covered cables in underground conduits	28,000	8
Armoured cables	184,000	55
Total	335,000	100

Various conclusions may be drawn from these tables. We will only remark that all the districts in Paris, some partially, some exclusively, make use of armoured cables. This system of mains offers, in fact, considerable advantages in large cities, where narrow thoroughfares are often met with, already encumbered with other underground networks, notably gas-mains. The cement conduits require a regular position in the street, whilst the armoured cables do not cause any trouble in this respect, but can be laid round obstacles. Besides, they are quickly laid, whilst the cement conduits require to be left for several days to set, which increases the duration of the obstruction to traffic.

Finally, with the use of armoured cables no empty spaces are created under the public road; and, in consequence, the presence of chambers charged with an explosive mixture of air and gas is not to be feared, but with cement conduits or metallic conduits which have good drainage these accidents are to be feared and have taken place. Such casualties can only be obviated by very careful attention to the ventilation of the underground conduits, as is at present given to the question in Paris.

It is as well to remember, moreover, that to-day armoured cable mains are more economical than those on the conduit system. In M. H. Maréchal's interesting work "L'Eclairage à Paris," pp. 229-231, there is a comparison of the prime costs of the various systems. It is shown that a main of three wires of 200, 100, and 200 square millimetres, for continuous currents, 240 volts, costs 31f. the metre with armoured cables and 33f. in *caniveaux*; and that a main of two wires of 60 square millimetres for alternating currents of from 2,000 to 3,000 volts costs 56f. in conduits and 24f. with concentric armoured cables.

It may, further, be noted in favour of bare cables that with them, without much trouble, the density of the current can be augmented, while with armoured cables there would be risk of damaging the insulating material through excessive heating. This consideration, it is true, can only logically be applied to the feeders, for the section of the distributors should be sufficiently large so that between two points of junction with the feeders the loss of voltage may be as little as possible, and, in any case, the question of heating does not need consideration. For the feeders themselves, when the consumption increases on the network to the extent that there may be occasion to think about the density of the current, it will be well to examine if it would not be better to fix a new feeder in place of consuming energy in the form of heat.

In brief, it may be said, with due respect of what experience may be able to teach us in the future, that where large towns are in question, where the exigencies of public traffic make imperative the use of underground cables, recourse as much as possible should be had to cable mains, comprising within themselves and simultaneously the double protection, electrical and mechanical, and placed directly in the ground, of the type called armoured cable.

If, for particular reasons, recourse is had to a system of mains formed of conductors placed in conduits, this method should only be adopted after careful investigation. Especially should the results already obtained be ascertained, and whether or not the conduit is waterproof, and in any case assure the immediate ejection of water if it should accidentally have entered.

The nature of the materials employed in the construction of the conduits should be considered. It would be well, as a rule, to avoid the use of glazed earthenware, and in the case of covered conductors the employment of iron hooks as supports for them.

Recourse should not, in principle, be had to metallic conduits. When their use is obligatory for special reasons, the cables in them should be insulated with the same care as if they were placed directly in the ground.

In the case of underground conduits it is as well to pay particular attention to their ventilation, and to prevent the accumulation of explosive mixtures of air and illuminating gas.

Finally, in every case steps should regularly and periodically be taken to measure the insulation of the conductors

USES OF ACCUMULATORS.*

BY J. C. HOWELL.

When I was first asked by one of the members of your council to prepare a paper upon accumulators, I was much concerned as to the course I should take, whether I should cry off on the ground that it was useless raking up the ashes of a dead industry, or boldly enter the vault in which low tension had been entombed, and seize what relics I could to bring before you of the wisdom of the ancients. Finally, I chose the latter course, and my investigations have been rewarded by the discovery of a leaden scroll upon which had been traced, evidently electrolytically, in characters of peroxide a long poetic prophetic account of the final triumph of electric storage systems, a rough prose translation of which I shall attempt to give you to-night.

The scroll commences with a long historic account of the

* Paper read before the Northern Society of Electrical Engineers, May 13, 1895.

Digitized by Google

birth of the first electric storage systems, describing in turn the early experiments of Gautherot, Ritter, Gaston Planté, with his leaden plates; Grove, with plates of oxygen and hydrogen fitted with platinum electrodes; Faure, Sellon, Volckmar, and a host of others, chronicles the historic passage across the channel of the box with its 1,000,000 foot-pounds of stored-up energy, and finally settles down to the sober consideration of the chemical actions involved in the charge and discharge of the cells, as the new boxes were styled. One cannot help admiring the ingenuity of the old scribe in twisting into proper rhythm long lists of chemical formulæ, but with these we shall not concern ourselves to-night, but hasten on to that portion where the uses to which accumulators were put are described with more or less detail, as being far more interesting to the majority of us who are, I understand, more connected with the practical development of electricity than with its theoretical and mathematical aspect.

The first uses to which these accumulators were practically put was for maintaining continuity of supply, or what is now called constant service, in country house electric lighting work. In the very early days of electric lighting it was discovered that in this class of work it was essential that the light should be available any hour of the day or night, and that people were prepared to pay considerable sums for the use of an apparatus which would give them this regularity of supply, and so avoid the necessity of keeping a man or men continually looking after moving machinery. Although the capital cost of these early accumulators was exceedingly high, it was speedily found that the annual saving effected by their use was sufficiently large to recompense the purchaser for his outlay, except in cases where water power was available. In gas-engine work, and with steam-engines, the accumulators were found to be working at their best efficiency at a time when, had the motorial plant been in operation, it would have been working at its worst efficiency, and instances are recorded where, by the adoption of accumulators, the gas bill had been reduced to 50 per cent. of what it was when the supply of electricity for household service was obtained from the dynamo driven directly by the engine, and this difference in a case where the former supply had not been constant service.

Unfortunately, the construction of these first accumulators was defective, and for a while accumulators became discredited owing to the frequent breakdown of the plates of which they were composed, and the falling away of the active material which permitted what we shall call the storage action to take place. By slow degrees these faults in construction were discovered and remedied. Then a more abstruse series of faults developed—viz., those due to the peculiarity of the chemical actions which were going on in the cell, and which required time to show themselves. These, too, in turn were carefully investigated by earnest men, who devoted their lives to research, until at last, by the law of the survival of the fittest, manufacturers were able to produce accumulators which they were prepared to guarantee and maintain for a series of years.

During this period other departments of electrical industry had not been idle, and the electric light had become so popularised that central stations were established for the supply of electricity. The public were at first contented with a supply which would suffice for the ordinary hours of lighting, but as they began to appreciate the benefits of the new illuminant they were not content with a partial supply, but required it at all hours of the day or night, and men's minds were directed to find some means for providing this supply in an economical way. Had the public been content to maintain their demand for lighting at a normal rate whenever they required it, it would have been easy for the central stations to supply electricity in an economical manner, but the public, proverbially fickle, required their supply in an extraordinary fashion. At certain periods of the day they were content to ask for only some 1 per cent. of what their normal demand was, and, moreover, required that the supply at this period should not be charged for at a higher rate than when the demand was just 100 times in excess. Although it had struck many long-sighted engineers that the public supply of electricity would have to be dealt with finally in much the same fashion as the public supply of water or gas had been dealt with, no one, the scroll narrates, had realised how greatly the demand for lighting at different times of the day varied, and the ordinary engineer greeted the publication of the first load curve of a central station that was published with a smile of wondering bewilderment. Such curves in the after history of electric lighting became common, and comparisons were instituted between curves obtained for various districts, various cities, and various countries, and it was found that there was a very considerable amount of uniformity throughout the world. In process of time, the different characteristics of the load curve for summer and winter were established, and it became more and more evident that, unless some satisfactory means of providing for this inequality of demand was discovered, electric lighting would for ever remain a luxury.

The accumulator manufacturers considered that they held the key to the solution of the difficulty, and at Colchester set down a system which was intended to demonstrate to all the world that the difficulty had been satisfactorily met. The problem was, however, unfortunately tackled by men who were probably thoroughly conversant with the batteries manufactured at the time, but had very little knowledge of the public needs, and after some years' work the scheme had to be abandoned, and other methods tried. The scheme had, however, in showing the difficulties to be encountered, shown also considerable promise for the future, and it was discovered that accumulators, to be of real service in central-station work, had to be capable of meeting for short periods demands considerably in excess of their normal capacity. This was difficult of attainment, as, owing to the chemical actions taking place on the plates which formed the active portion of the accumulator, any supply of electricity drawn at too rapid a rate would tend to break down the materials which composed the plate; and, furthermore, did not provide sufficient time for the electrolyte to diffuse itself so as to keep up the chemical reactions involved in the supply of electricity. This fact being properly appreciated speedily led to the development of accumulators which could, on being called upon, discharge at very rapid rates, and, although these accumulators were costly, it was discovered that their freedom from breakdown in trying circumstances was such as to warrant a trial being made on a sufficiently large scale to see whether this new form would be fully equal to all the requirements of central-station practice. Reliable statistics, too, were at this time available, so that engineers could fully realise the costs of working under the peculiar conditions which the public demanded, and it was found that the cost of fuel was from four to six times what had been expected from the results obtained when working an engine and dynamo under test. The facility with which electrical measurements could be made had trained men's minds for the investigation of the various losses occurring in the transformation of energy, and central-station engineers became more and more aware of the necessity of dealing with all these losses so as to enable them to compete on more and more favourable terms with other systems of illumination that had been in vogue.

A discussion upon these sources of loss and the way in which by the use of accumulators these losses can be minimised is the real object of the leaden scroll, and to make matters clearer I have placed before you to-night curves of the efficiency of a steam-driven dynamo at various loads, from which you will see that the quantity of water required to be evaporated per unit working at 20 per cent. of its load is more than twice as much as when it is fully loaded, the figures being 33lb. of water per unit at full load and 73lb. at one-fifth load.

NON-CONDENSING WILLANS SET.

Engine load-factor.	Pounds of coal per unit.	Cost per unit of coal at 20s. per ton.
20 per cent.	7·3	·78d.
30 ,,	5·4	·57d.
40 ,,	4·75	·5d.
50 ,,	4·3	·46d.
60 ,,	4	·43d.
70 ,,	3·75	·4d.
80 ,,	3·5	·37d.
90 ,,	3·4	·36d.
100 ,,	3·3	·35d.

Similar engines, when dealing with the business of supply, have been tested by Prof. Kennedy at actual work, and he has been good enough to publish his results. These results I have embodied in a table, to which I shall refer you, and I have amplified them somewhat so as to give us sounder ideas of what the figures actually mean by attaching a value to the ton of coal. This value may appear high to you in this district, but it is the price that rules in London, where at the moment there is a greater production of electrical energy for lighting purposes than in all the rest of the United Kingdom put together. Moreover, it is a comparatively easy matter to mentally reduce the figures of the table based on a standard price of 20s. per ton to the figure which rules in each investigator's district.

KENNEDY TABLE OF CONSUMPTION ON VARIABLE LOADS.

—	11 a.m. to 6 p.m.	6 p.m. to midnight.	Midnight to 11 a.m.	Whole day.
Time	7 hours	6 hours	11 hours	24 hours
Total indicated horse power-hours	562	1,366	407	2,335
Total electrical horse-power hours	400	979	260	1,639
Units generated	293	731	193	1,217
Coal consumed	3 838lb.	4,459	2,547	10,844
Coal per unit	13 1lb.	6 1	13·2	7·33
Coal at 20s. per ton	1·4d.	·65d.	1·41d.	8d.

Take as an example of the use of Table I. that we have 100-unit steam dynamo running at maximum efficiency. It will need under the most perfect conditions of running 3·3lb. of coal per unit per hour, or 330lb. Increase the load upon our station 20 per cent., and we have to start another similar set, so that

Digitized by Google

the load is divided between them; each set is now working at 60 per cent. load-factor; the amount of coal consumed is 4lb. per unit, or 480lb. Thus an increase of 20 per cent. in the load involves an increase of 45 per cent. in the coal consumption, and the actual loss owing to the decrease in efficiency is 9½d. per hour in the coal bill alone as long as the 20 per cent. extra load is maintained. That these losses are real and are actually found to exist in practice we will at once discover by reference to the Kennedy table, where we find that there was less coal burned during the period of heavy load than during the period of lighter load—that, in fact, 63 per cent. of the total amount of fuel consumed was used to provide 33 per cent. of the output. It will be of interest if we examine this table closely. The day on which these tests were taken was divided into three parts closely corresponding with the times as shown on a load curve where you have a minimum demand, moderate demand, and maximum demand. You will notice that the amount of coal required for the moderate demand approaches very closely to the total amount required for the maximum demand, and that during the period of minimum demand, when only some 20 per cent. of the maximum output was delivered, the coal bill reached the respectable figure of 57 per cent.

Let us pursue our investigations a little further, and we will see that during the period of lighter load 6,385lb. of coal were consumed, an amount sufficient working at the rate shown during the period of maximum demand to produce 1,050 units, or very nearly the total daily output required. Had we been therefore only able to provide some suitable means of storage which would have allowed us to run our engines at a fair rate of economy, there was a possible chance on that day's output of effecting a saving of two tons of coal during the run, or, say, £2 sterling, an amount which would perhaps go some little way towards meeting the resident engineer's salary.

That there is a practical difficulty in so running a central-station plant as to work at anything like a fair efficiency, no one but a central-station engineer has fully realised, and I should like here to emphasise what I have long felt, that we hear too little of the central-station engineer. It may be that the exigencies of his work preclude him from attending meetings and speaking thereat, and I can well understand that the problems continually thrust upon him absolutely forbid his devoting much time to writing papers, but if he only realised what service he could render to the manufacturers, who are always anxious to supply him with what he wants, he would, I think, strain a point, and give the world knowledge of his necessities. To give you some conception of the problem that the resident engineer has to solve, I have prepared a diagram showing you the output of an American station which I visited some time ago, and I have plotted in the way in which the load was dealt with.

The plant at their disposal was capable of dealing with a maximum output of some 18,800 amperes made up in four sets of 2,000 amperes each and nine sets of 1,200 amperes. You will note from the marginal scale at the side that at no time during the day did the station touch an engine load-factor of 80 per cent. except for a few minutes at the peak of the diagram. I have coloured the various engines so that you can more clearly observe what happened during the day. You will see that, starting at one o'clock in the morning, set No. 15, coloured black, was kept running nearly the whole 24 hours; that set No. 11 ran from one o'clock till half-past nine, and, if you carefully note the level that No. 11 set, combined with No. 15, would have taken, you will observe that during the whole period of minimum demand the engine load-factor did not reach even 60 per cent. as an average. You will further observe that at seven o'clock, when the load commenced to rise, the additional load had to be dealt with by adding small set after small set, and it was only when the load was rising so rapidly near the peak were they able to fully utilise the larger sets which ought *a priori* to be more economical to run than the smaller sets. The same criticism will apply on the down grade when the demand was decreasing. The coal consumption at this station on the day on which the curve was taken was 80 tons. On further reference to this curve, you will see that the two larger engine sets were kept going at as near their maximum output as in American practice is considered safe, taking the sudden abnormal changes of load into account, and that the balance of the load was equally divided over all the other sets that were at the time running. The result of this complicated system is that although by the number of engines running the efficiency of each is somewhat increased, the regulation of the pressure on the mains is more difficult, as the adjustment to standard is only really effected when the current from the last machine is properly adjusted. That the labour involved in this adjustment is considerable is easily understood on reference to the diagram.

Reverting once more to the leaden scroll, I find that almost all our later knowledge with regard to the varied load-line had been duly considered, and methods are described very fully by which the use of accumulators would relieve the central-station engineer from all anxiety as to his variable demand, and following closely the instructions laid down in the scroll, I have prepared a chart showing how the methods there described would deal with the load curve which I have put before you. We are told that we must first ascertain the output for the period of minimum demand, and for what time the minimum demand lasts. These figures enable us to ascertain the capacity of the accumulators required. We observe that this period of minimum demand is very clearly defined on our load curve as lying between 1 a.m. and 7 a.m., a period of six hours. During this time an average of 2,100 amperes have been delivered to the circuit or, say, in round figures, a total of 13,000 ampere-hours. To provide for this output and allow a margin for contingencies, we shall require a set of accumulators having a capacity of 14,000 ampere-hours. An enquiry addressed to modern accumulator manufacturers has brought me the information that such a battery would cost delivered and erected £7,000.

On adding this battery to the equipment of the station and closely observing the rules and regulations laid down in the scroll, I find that the result upon the working of the motorial part of the machinery is that whenever an engine is started it can be kept at full load from the moment it starts to the moment it ceases running, thus bringing up the efficiency of the station to 100 per cent. engine load-factor at once.

Observe the result on the load diagram. Instead of the patch-work jumble of in and out engine loads, we have each set working steadily at full output as long as is required; that the hours of running have been shortened from 24 to 18, thereby lessening the number of men employed. More than this, we have been able to commence running with three of our large sets at full load from the moment of starting up to 7 a.m., and that these engines run steadily throughout the day. We notice also that when the load increases, the accumulators, although discharging during the early morning hours, have already received sufficient charge to permit a discharge until three more engine sets can be started simultaneously, pointing out the advisableness of employing fewer sets of larger plant for this station.

The only regulation required is the steam pressure at the boilers, which must be kept constant, and a slight increase in the speed of the engines as the load creeps up to compensate for the slight additional loss in potential in the feeders leading the current away from the station.

Follow the curve still further, and we come to a period when the engineer has to exercise his judgment as to whether he will let his battery deal with the peak or run one of his engine sets. He chooses the former course, and to provide for it he starts his blue set, and keeps it running for several hours before the peak actually occurs. You will observe that at the time when this peak is about occurring, he again starts three sets simultaneously, and the peak itself is allowed to come from the battery. Three times during the day, therefore, has he to start some plant, and in each case you will observe that he has been able to put on three sets. Only once is it necessary for him to start one of his engines alone.

Now, I shall very probably be told that, owing to the variation in the E.M.F. of the battery during charge, the regulation of the charging current will be an exceedingly difficult matter. A diagram carefully copied from the leaden scroll will show at once how exceedingly simple this regulating matter is. One of the steam-dynamo sets is expressly made to give just the current rate necessary for properly charging the battery and no more. The set devoted to this work in the station before us is the black No. 15. This set is capable of charging the battery at 2,000 amperes, and the dynamos are so wound that, when necessary, higher volts can be obtained from this set than from the other sets. It is the first to be started up and it is the last to leave off, and is during the whole day prepared to charge the battery except at the time when the output called for is in excess of the current generated by all the sets in combination. It is kept permanently attached to the regulating ends of the battery, as you will see from the diagram. An adjustable switch is so arranged that the terminals of the machine can be attached to any cell in the regulators, so that as the end cells get charged up the switch may be moved down until it reaches the cell which is in connection on the discharge side with the terminals of the other sets and with the circuit.

You will note, also, that the loss in charging the accumulators is very slight, as it is only felt by one unit of the plant, and is really in the load diagram before you only 1 per cent. of the total load delivered to circuit, as the proportion between the load dealt with by the accumulators and the total output is just slightly over 8 per cent. But what have we gained? Even the most casual glance will show you how immensely simplified the station work has become—a certain number of engines running, a certain amount of steam required, the engineer in charge directing everything with quiet confidence, knowing full well that he has a big reserve always behind him capable of dealing with an extraordinary demand or with any little accidental occurrence, such as a hot bearing or low steam pressure. In a well-regulated central station, with a becoming amount of pride, such accidents should, I am aware, never happen, but I am credibly informed that they do sometimes occur.

Digitized by Google

But these, after all, are only minor advantages. No board of directors has yet, as far as I am aware, sanctioned an item for depreciation of engineering staff appearing on a balance-sheet, and we must look for more solid grounds of economy before we can appeal to them. A comparison made between the two curves will at once show you that the labour bill will be considerably reduced by the employment of accumulators, and the amount of the saving is thus shown by Table 2 to be £1. 15s. 6d. a day.

STAFF REQUIRED TO WORK CENTRAL STATION.

Without accumulators.				With accumulators.			
10 greasers at 4½d	... £1	7	6	8 greasers at 4½d.	... £0	18	8
6 engineers at 8d.	... 2	0	0	5 engineers at 8d.	... 1	10	0
11 stokers at 5½d.	 2	10	5	9 stokers at 5½d.	 1	17	1
3 switchboard attendants at 8d.	 0	16	0	3 switchboard attendants at 8d.	 0	16	0
				2 battery men at 8d..	0	10	8
30	£7	3	11	27	£5	12	6

Difference—£1. 15s. 6d.

The coal bill will also shrink, as we have ceased running our engines during the period when we are using our coal most wastefully, and, moreover, we are able to run our engines at full load whenever they are running. Carefully working out the amount of coal required for each engine, we shall see that we have brought down the amount from 80 tons (which I have mentioned as being the amount consumed on the day on which this load curve was taken) to 67. Our oil bill and petty stores have also been reduced in almost the same proportion, and it is probable our bill for repairs to the motorial portion of our plant will be decreased somewhat, although this I will not at present take into account. You will also have observed in your comparison of the two curves before you that three engines that were at work in the first curve have not been required to run at all in the station when fitted with its accumulator system. We thus save the lubrication bill on these engines entirely, and the saving has been therefore:

Labour bill	£1	15	6
Thirteen tons of coal	13	0	0
Lubrication, say		4	6
Repairs		—	
	£15	0	0

But in order to effect this saving we have been compelled to make an outlay of £7,000 in a class of plant which, in the minds of most engineers, should submit to a heavy charge for depreciation. We have not forgotten this, and will therefore set aside a sum sufficient to meet the views of these engineers by putting on the other side of our account an amount of £2 per day for depreciation and £1 per day for interest on the outlay.

The extra staff required to look after the accumulators has already been dealt with in our labour table. The net saving therefore is reduced to £12 per day, or, say, £4,380 per annum, an amount sufficient to wipe off the whole capital cost of the accumulators in two years, and still leave a margin to go to the profit and loss account. The load curve you will see is dated June 23, and you will readily understand what this means.

Now these figures are facts, and can be proved up to the hilt. They do not admit of argument, and since they apply to a station arranged on a scale very much larger than anything we have hitherto built in this country, they effectually dispose of the usual modern criticism that accumulators may be very well adapted for small stations, but are absolutely inapplicable to supply stations dealing with large outputs.

Another criticism, and a fairer one, would be that by taking coal at a value of 20s. per ton I have exaggerated the saving on the capital outlay. This is true, but those who care to puzzle out the problem will find that the economy is sufficiently marked at any value for coal to warrant the adoption of accumulators, and they will also find that the only satisfactory method of doing away with accumulators entirely is to work up their demand curve to a straight line extending over the whole 24 hours, an occupation which the old scribe quaintly observes "will take them all their time."

It will be seen, therefore, that wherever there exists an intermittent demand for a supply of electricity an electrical storage system is a necessity, unless the cost of the initial power is so abnormally low that the interest charges on the accumulator outlay amount to more than the annual saving to be effected. Such causes do sometimes occur when an abundant supply of water is available close at hand.

Intermittent demand for power is the rule in the majority of our manufactories to-day, and although hitherto we have been content to meet this demand by transmitting our power by means of steam-pipes, countershafting, and belting, the day is not far distant when electrical methods of transmission will be the rule and not the exception. In all these cases the leaden scroll is emphatic in pointing out the application of accumulators, and you will readily perceive from what has already been said that to obtain the utmost economy accumulators will be absolutely necessary; for they enable us to reduce the initial power put down, and, furthermore, permit us whenever the utilisation of the power takes place some distance from the spot where it is generated to economise in the conductors, as they need not be of a sectional area greater than will carry the average current instead of the maximum with efficiency.

In this district, where underground transmission of power is becoming more and more common in all your collieries, you will assuredly find in the near future batteries of accumulators installed in the underground galleries in chambers such as you see on the wall, the difference in value of the highly-insulated conductors leading in-bye having been found to cover the cost of the system of storage, without taking into account at all the other economies found to exist in the maintenance of the plant. Already electric railways have adopted electrical storage systems for equalising their load and maintaining more equal potential over their lines, thus ensuring a regularity of train service not to be attained by any other means.

I could go on quoting from the scroll, pointing out numberless other instances where accumulators would be of the greatest service, but our time is already far spent, and I shall not weary you to-night by elaborating the matter further. There is, I think, a sufficient basis of fact on the scroll to warrant our seriously considering whether the methods we are to-day adopting for dealing with the electrical supply of towns are in the majority of cases the most suitable methods, and I feel sure that the question of coal economy has not been gone into with anything like the care it should be in the design of many stations now at work and in course of construction. The high coal bill shown in many districts where coal is cheap is sufficient evidence of this. I trust, therefore, that the discovery of this scroll may be of some slight service in drawing the attention of the younger members of our profession to a closer study of this question, and I shall be only too pleased if the discussion on the points raised will lead to greater interest being taken in the subject.

TELEGRAPHY BY INDUCTION.

Mr. W. H. Preece delivered an address with this title yesterday (Thursday) before the members of the London Chamber of Commerce in the hall of the Carpenters' Company, London-wall. Sir Albert K. Rollit presided. The lecturer said that he had adopted this title to distinguish the subject of his address from "telegraphy by conduction," the common mode of working. He referred to the efforts of Morse in 1842, and of Lindsay in 1854, to solve the problem of telegraphy by induction. One of his earliest experiments was made for Lindsay in that year. "Telegraphy by induction," he said, meant signalling through space by electromagnetic waves without any conductor joining the points between which communication is desired. A somewhat analogous process was the use of the heliostat in India, by which signals flashed by the rays of the sun conveyed information from Chitral to the relieving forces. In this latter case the instrument that received and translated the signals was the eye, but in the experiments that were then being discussed the receiving instrument was the telephone, an exquisite apparatus of precision and research, as well as a simple instrument of utility. If Faraday had possessed the telephone, electricity as a science would have been advanced perhaps a quarter of a century. In 1884, his interest was excited by the fact that an operator in a telephone company's exchange-room in the neighbourhood read some messages that were being sent to Bradford from the General Post Office through a wire in an iron pipe laid underground in Gray's-inn-road, although the telephone wire ran along the housetops 80ft. away. An exhaustive series of tests and experiments proved beyond all doubt that this was a case of pure induction. Space was filled with a medium, called the ether, through which numerous waves of energy—radiations—were propagated with the same velocity, but in different forms and with different frequencies. At one end of the scale extremely minute radiations undulating many million times per second gave us photospheric effects; others less rapid gave us light; then we had radiant heat, and when we came down through a great range to a few hundred per second we had electromagnetic waves which obeyed the same laws of reflection, refraction, interference, and polarisation. We had to regard (1) the source of energy—the transmitter; (2) a medium for the transmission of the radiations; and (3) an instrument to transform the radiations back to the original form of energy—the receiver.

The lecturer next spoke of Faraday's discovery of electromagnetic induction, the principle of many valuable inventions, but Faraday (and the lecturer assisted him in his enquiry) tried to find these currents in our telegraph wires and failed. He (Faraday) knew they were there, but he could not trace them. They were subsequently found in long parallel wires in dry climates, like those of India and Persia, but it was not until 1884 that they were traced with certainty, and that was in Gray's-inn-road, London. The fizzing, frying sounds in other currents so annoying in our telephones were due to this induction. In 1885 an induction experiment in the neighbourhood of Newcastle traced the effects to a distance of 2,000ft. Distinct speech was carried across a space of a quarter of a mile. In 1886 experiments in the valley of the Severn measured disturbances through a distance of 4½ miles. The wide expanse of sand on the South Wales coast, well covered by the tide, enabled experiments to

Digitized by Google

be made in air and water, and showed that the inductive effects were equally observed in each, and in 1892 actual messages were sent across the Bristol Channel from the mainland to Flatholm. Subsequently, speech by telephone was easily maintained across Loch Ness, on the Caledonian Canal, a distance of 1¼ mile. Later, signals were passed between Arran and Kintyre, four miles apart, but the final practical success was obtained in March last. The cable connecting the Island of Mull with the mainland near Oban having been broken, it was decided, pending the arrival of the cable-ship charged with repairs, to establish communication across the channel by this means. The width of the channel at the point selected for the inductive circuit varied from 1¼ to 2 miles, and skirting the coast of the island an overhead wire existed between Craignure and Aros in a position well adapted to the object in view. The distance between this wire and the mainland was almost uniformly two miles. As there was no existing wire on the mainland parallel with and sufficiently close to the Aros-Craignure circuit, a guttapercha-insulated wire was laid along the ground from Morvern in a north-westerly direction for a distance of 1½ mile. It was earthed at Morvern in a running stream nearly a mile away from the sea, at the other end in the sea.

The apparatus connected to each wire consisted of (*a*) a rheotome or make-and-break wheel, capable of causing 260 undulations per second; (*b*) an ordinary battery of such voltage as to send a sufficiently strong current through the circuit—in this case dry cells were used for portability; (*c*) an ordinary Morse key; (*d*) a telephone to act as a receiver. The rheotome consisted of a small electromotor driving a divided disc that rapidly made and broke the current the requisite number of times. It was joined in multiple with the line and the main battery. Good signals depended on the rapid rise and fall of the primary current; this intermittent current was broken up into Morse signals by means of a key, these signals being read on the telephone connected to the opposed circuit. Communication was satisfactorily established on Saturday, March 30, although, owing to the fact that telegraphic communication was possible did not become generally known till later, only one message was transmitted on that day. Up to and including Wednesday, April 3, a total of 156 messages was despatched, including one Press message of 120 words. The cable was repaired on the last-named date, and the ordinary method of transmission resorted to. The official at Mull reported, "I do not think an ordinary Morse circuit could have given better results." Curiously enough, he also reported that "the chief difficulty was the incessant screaming of the sea fowl," while "strong earth currents interfered very much." He (Mr. Preece) attributed the "screaming of the sea fowl" to a very different effect. Strange, mysterious, weird-like sounds were frequently heard on long lines of telegraph in the calm stillness of the night, but whether they were due to terrestrial or to cosmic causes remained to be discovered. The sun's photosphere when disturbed by spots might be subject to violent electrical storms, and those vast clouds of incandescent hydrogen that flamed up with terrible velocity might excite electrical oscillations through ethereal space of such a frequency as to influence our terrestrial circuits. We might thus hear on earth the electric storms of the sun. It was difficult (the lecturer concluded) to forecast the future of this new telegraphy, we had signalled in one direction only, but there was no reason why we should not duplicate and quadruplicate our messages. Each particular circuit had its own sympathetic frequency, and each telephone responded more energetically to one particular note better than to any other, and we could take advantage of these two facts.

INSTITUTION OF ELECTRICAL ENGINEERS, May 23.

MR. R. E. B. CROMPTON (President) in the chair.

At last night's meeting of the Institution the following candidates were balloted for:

Foreign Members.—Clarence L. Cory, University of California, Berkeley, California; Albert Petersen, Norwegian Government Telegraphs, Arendal.

Member.—Alfred Dickinson, 120, Colmore-row, Birmingham.

Associate.—F. Z. Maguire, 70, Oxford-street, W.

Student.—Charles Flindell, Faraday House, Charing Cross-road, W.C.

The discussion on Mr. Mark Robinson's paper, "On the Recent Development of the Single-Acting High Speed Engine for Central Station Work," was resumed by **Mr. Siemens**, who stated that with regard to the Newcastle tests made by the speaker, to which the author had referred, it should be borne in mind that they were conducted in connection with the first Belliss engine made, and that doubtless better results could now be obtained.

Mr. Chandler said, with reference to the author's remarks regarding slide-valve rings, that it would be very interesting to all advocates of piston valves to know what really were the conditions of pressure at the back of the rings.

Mr. Morecambe took exception to portions of the author's paper. His firm, he said, had an engine at least as good as the Willans, and he hoped to prove this statement. The engines in the Navy for electric lighting purposes were, at one time, nearly all single-acting engines, but the Admiralty was now permitting double-acting engines to be used at the same time. He had heard a friend in the Navy say that they had not time to properly repair Her Majesty's ships, as the Willans engine absorbed so much of their care and attention, owing to collapses. The double-acting engines had not shown these breakdowns. Comparing the single-acting engine with the double-acting engine, there was always the fact that when you had twice the area of the piston there would be a strain along each rod, and, under ordinary circumstances, double the wear. There was not a halfpenny between the two engines as far as economy was concerned. As to durability, he referred to the very numerous parts of the Willans engine, especially the rings, as a drawback in this respect. As to governing, this was a point to which his firm had turned their attention during the last three months. The double-acting engine governed quite well enough. With respect to vibration, there was no reason why the three-crank double-acting engine should not be equal to the single-acting engine. He advocated an impartial trial of the respective merits of the two engines.

Mr. Wright, who had used Willans engines to the extent of 2,000 h.p., had nothing but praise for them. In all his experience he had never had a mishap. He had absolutely no fault to find with them. The whole of the horse-power was managed by two men and a boy.

Mr. H. Halpin, referring to the 90 to 94 per cent. efficiency claimed for the common engine, said he could certainly not believe in figures of that kind unless he had means of verifying them.

Mr. Geipel enquired whether it was correct to state that the high-speed engine would last as long as the slow-speed machine, and whether the early renewal of the one would not balance the increased first cost of the other. Was not, moreover, the method of overcoming the vibration indicated by the author a further argument in favour of using the slow-speed engine for light loads?

Mr. Shoolbred had seen the Willans engines working from time to time, but could not eulogise them like Mr. Wright, as the throttle valve was a blemish. The engine must be kept fully loaded in order to be worked economically. Many arrangements had, however, been made by which the engines could be kept worked up to their mark in central stations from 75 per cent. to full load. At Pontypool the use of accumulators to keep the engines at full load was interesting, but the question arose how much was being paid through the accumulators for this economy. The Willans engine in itself was in many respects more satisfactory in working than double-acting engines, as, for example, in steadiness and silence. The Willans engine was less the engine of the future than of the present, for when one came to large powers, double-acting engines would come into the field,

Mr. R. Allen said that an important point was the crankshaft, as it was difficult to get them made true. The Willans engine was not to blame in the case of Admiralty accidents. He himself had found his engines on board ship had been spoilt by bad management.

Mr. Dumas had had to do with Willans engines on board a man-of-war, and found the interchangeable system a very great advantage. Having discussed the question of the piston rings and the wear in the cylinder, he said that lubrication had a very important bearing on the subject. He wanted to know whether there was excessive wear at the bottom as compared with the top. The mechanical efficiency of the engine would be increased if cushioning could be dispensed with.

Mr. Head also alluded to the lubrication question, and, referring to an experiment he had carried out with a Brotherhood engine, said he had been impressed with the fact that single-cylinder engines were liable to fail unless oil could be pumped in at pressure.

The **Chairman** stated that it was 19 years since he bought his first Willans engine, and he had been using them constantly since. Mr. Robinson had been unworthily accused of seizing the opportunity of discussing high-speed engines to push forward his own, but he was right in giving his own experiences, and not hearsay evidence. He was a friend of the Willans engine as a high-speed engine, for high-speed engines had been the making of electrical engineers. There was no difficulty in taking down the engines and fitting them together again. The makers of enclosed engines were doing the right thing, and he did not mind if they were complicated inside as long as the steam went in and power came out, and there were no difficulties. No doubt the outcry of the advocates of the Lancashire practice had, unfortunately, some influence, but the results would prove unsatisfactory compared with those from high-speed engines. The cost of repairs in central stations was as low or lower with high-speed than with slow-speed engines. There was every reason to be extremely proud of what Thames Ditton, Belliss, Chandler, and other high-speed engineers had done.

Mr Robinson, in reply, said he had not dealt with other high-speed engines, because in central-station work the Willans was the only one which had taken much of a place. It did not require long, as had been suggested, to get at the inside of the engine. Improvements had been credited to him, but he desired to say that such had either been made by Mr. Willans before his death, or had been based upon experiments made by him. He would have referred to the Chandler engine, but little had been published about it. Mr. Morecambe had referred to a duel between double-acting and single-acting engines. This was exactly so, and the speaker was a supporter of the principle of the latter. The air cushion to which Mr. Dumas objected did not receive fair treatment in the navy. There were 100,000 h.p. of Willans engines at work, and they were running without trouble. The economy shown by the Belliss engine at St Pancras was good, but the tests had not been made over an extended period. As regarded durability, there was no sign that there would be any difficulty with the engines in this direction. As regarded the question of light loads, the station, as Mr. Shoolbred had pointed out, should be run so that the engines should not be lightly loaded.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 month
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank.'*

BOUND VOLUMES.

Vol. XIV. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers or binding can be obtained, price 2s.

CORPORATION POLICY.

We have emphasised again and again our opinion that the governing bodies of large towns should keep the electric light supply in their own hands, and not allow the monopoly to be in the hands of companies. When they have not done so, but have allowed the new industry to be left to the tender care of so-called local companies, which in reality are controlled by contractors, we do not hesitate in saying that the ratepayers have suffered both in the regularity of supply and in the price charged. The machinery installed by such people is usually selected with a view to the contractor's profit, and charged to the company at full list prices. Still, in some large towns genuine companies have worked provisional orders with a view to dividends to be fairly earned from the supply of electric light. These companies, after years of working, have reached the dividend-paying stage, and convinced the corporations that electric lighting is commercially a success. What follows should be a lesson to all town-governing bodies. The authorities naturally wish to acquire the rights which years before they had allowed to fall into other hands, and also wish to do so now before the price for the undertaking rises abnormally, as the prices for water and gas companies' rights have risen. Two remarkable instances will bring the lesson home. At Liverpool, Sir Frederick Bramwell has decided, on behalf of the Corporation, that a fair price for the company's rights and machinery would be four hundred thousand pounds. Now, the company has only spent some two hundred and fifty-two thousand pounds on the plant which will be handed over, and we are assured by Mr. Preece that even then the Liverpool Corporation will not be in any better position as regards output of generating plant than the Manchester Corporation, who have only spent one hundred and seventy-four thousand pounds. Again, at Newcastle-on-Tyne, the Corporation wish to buy back what in 1887 would have cost them next to nothing—*i.e.*, the right to supply their own ratepayers with electric light. The price there is yet to be fixed, but from Prof. Kennedy's report it will be gathered that this figure will have to be considerably higher than the capital outlay. The low price charged by the directors of the two enterprising companies in Newcastle has done much to increase the number of consumers, and with the present load they would be able to pay a very large dividend if their price was fixed at sixpence per unit instead of fourpence halfpenny to fourpence three-farthings. That they have already paid or could pay 5½ per cent. dividend while charging this price is a credit to their engineers. We consider that companies who, like those above mentioned, have exploited the work successfully with their own capital should receive fair prices for their stations. Another place where negotiations are going on is Taunton. Here the conditions are not similar to those in Liverpool and Newcastle, and remembering Mr. Kapp's report to the town in May, 1892, we do not suppose the price paid will be high. We still hold that the corporations or local authorities can undertake successfully the electric lighting of their districts,

Digitized by Google

and do the work better than any company. At the same time we deprecate the attempts of certain syndicates to force the hands of the authorities in these matters for the sake of promotion money.

CITY GUILDS EXAMINATION.

As mentioned in our issue of May 10, we propose offering to the students who send us in the best set of answers to the recent papers, book prizes as follows:

For the best set of answers in the honours grade, any books on our list to the value of three guineas.

For the best set in the ordinary grade, books to the value of two guineas.

For the best set in the preliminary, books to the value of one guinea.

We leave it to the honour of the competitors that they do the work unaided, and that the answers are their own individual work. All answers must reach us here on or before Saturday, June 15. The successful students' answers will be published in this paper as soon as possible after that date, together with a *résumé* of the common points of error. Our list of books can be obtained on application.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

FIRE RULES.

SIR,—I was somewhat surprised at parts of Mr. Musgrave Heaphy's letter in your last issue, and wonder if he has the authority of the Phœnix Fire Office to damn, unread, the rules for electrical installations inside buildings about to be issued by the Institution of Electrical Engineers. He also seems to assume, on what ground it is impossible to see, that these same rules will cause fires, and that all insurance companies and electric light contractors must handle them with great care. While acknowledging the value of the rules prepared by Mr. Heaphy, I should value still more highly a set of rules prepared by such eminent engineers and electricians as have the matter in hand for the Institution. It would be most interesting if Mr. Heaphy as a prophet would state what the faults in the unissued rules will be.—Yours, etc., SALAMANDER.

DUBLIN TRAMWAYS.

SIR,—I have read your article on the report of Mr. Robert Hammond to the Dublin United Tramways Company with feelings of interest, amusement, and envy—interest in your views generally, amusement at your inconsistencies, and envy of your power of making statements which are unsupported by facts.

Your inconsistency is shown in your desire to make the local authorities discard their present fire-escapes for others which you consider more suitable, but which, so far as this country is concerned, remain untried on a large scale, and the fact that you wish the span-wire system to be adopted because it has been so successful in America; and the South Staffordshire system, although working with every success, is of recent introduction and something new. You go on to refer to the South Staffordshire system as a country line. This system runs through the main streets of Walsall, Wednesbury, and Darlaston. Walsall has a population of over 80,000, Wednesbury 25,000, and Darlaston about 16,000. The total length of lines is eight miles. The number of car miles run in 1893 was approximately 300,000, and the number of passengers carried 1,667,396. If this is your idea of a country line, your views as to a town line would be interesting.

You admit that the South Staffordshire system is an ingenious one, and suggest that the method was adopted because the track is near to the kerb. As a matter of fact, at no point is the line nearer to the footpath than 9ft. 6in., and in many places it is more than 26ft. from the footpath.

You apply "American" practices to English towns, where the conditions are altogether different. The "American" streets, as a rule, are broad and straight, and even under such conditions the overhead structure is not beautiful owing to the necessity of making the trolley wire follow exactly the curvature of the track. The route of the South Staffordshire electric line is a most tortuous one, the line is mostly a single line with turnouts, and if the wiring had been carried out on the "American" principle it would have been a most hideous sight, and would have formed a complete network overhead.

In reading your article, one would assume that if the difficulty of the passage of the fire-escapes down the streets was overcome by the introduction of horizontal ladders, that the great objection to the span wire would be removed. This, I think, shows your lack of knowledge of tramway working.

In America and on the Continent, speaking generally, such a thing as a tramcar carrying outside passengers is an unknown vehicle. In this country the most popular part of a tramcar is the top or outside seats, and great as may be the confidence, from an electrical point of view, of the public in an overhead system, I doubt whether they would ever reach that stage of confidence where they will place themselves directly under the trolley wire, with the liability of decapitation by the falling of a span wire.

I am sorry, Sir, that you have not yet realised that "if the mountain will not come to Mahomet, Mahomet must go to the mountain." My experience of the local authorities in this country is that they will not have the span-wire system. My knowledge of the travelling public upon tramways is that they will insist upon having outside seats, without awning over the top, and they will not expose themselves to the danger of riding under a wire when it can be avoided. My certain knowledge of the working of various overhead span-wire systems is that your statement that the span-wire system, in certainty and economy of service, is better than the South Staffordshire system, is an entirely erroneous system.

Your suggestion, that the best method of supporting the trolley wire for the tramway track in broad streets is the centre pole, may be a correct one when you start *de novo* with a tramway, and can so arrange the spaces between the tracks as to remove any cause of danger to passengers riding on the cars by striking the poles, but their adoption on lines already laid in this country would be a very great mistake, and would, in my opinion, lead to many serious and fatal accidents.—Yours, etc., JAMES L. OWEN.

120, Colmore-row, Birmingham, May 18, 1895.

WHAT, WHEN, AND WHERE.

CITY AND GUILDS OF LONDON INSTITUTE TECHNOLOGICAL EXAMINATIONS, 1895.

ELECTRIC LIGHTING AND POWER DISTRIBUTION.

ORDINARY GRADE.

Instructions.

The candidate must confine himself to one grade only, the ordinary or honours, and must state at the top of his paper of answers the grade he has selected. He must *not* answer questions in more than one grade.

If he has already passed in this subject in the first class of the ordinary grade, he must select his questions from those of the honours grade.

In the honours grade the student may, during the examination, use an electrical engineering pocket-book, but if he avails himself of this he must state the title of the book on his answer paper, and in his answers give references to the pages of the book he has consulted.

The number of the question must be placed before the answer in the worked paper. Three hours allowed for this paper. The number of marks obtainable is the same for each question. (Not more than *eight* of the following questions to be answered.)

1. Describe and give a full-size hand-sketch of one of the modern kinds of electrostatic voltmeters.
2. What is the use of the series coil in arc lamps run in series with an unvarying current?
3. Sketch a drum armature showing the connections and windings for 24 conductors on the outside. Sketch also any methods of end connection for drum machines in ordinary use.
4. What are the advantages and disadvantages of running incandescent lamps at high efficiency?
5. Draw a solenoid showing roughly the lines of force before and after the introduction of a soft iron core.
6. How does slipping a copper tube over the core lessen the spark of an induction coil?
7. How would you wind a medium-sized motor (say 10 h.p.) to run at constant speed with varying load? And how would you start such a motor?
8. What are foot-pound, poundal, dyne, and kilogram-metre? And how are they related?
9. If 10,000 kilocoulombs are passed through cells arranged in series containing solutions of Cu_2Cl_2, $Hg_2(NO_3)_2$, $CuSO_4$, H_2SO_4, and NaCl, how much copper, mercury, hydrogen, and caustic can be obtained?
10. What are the advantages and disadvantages of the Planté and pasted plates for secondary cells?
11. What are the advantages of separate field magnets for the two armatures in continuous-current transformers?
12. A series dynamo has an armature resistance of 0·4 ohm, and a field resistance of 0·6, and gives 120 terminal volts at a given speed and current of 10 amperes: work out its electrical efficiency as a dynamo and as motor at that speed and current.
13. Describe one kind of alternate-current motor.
14. When are alternate-current systems better than continuous-current systems? Give your reasons as fully as possible.
15. What peculiarities are there in the design of a dynamo for supplying arc lamps in series at (say) 3,000 volts?
16. Give a rough scheme of a switchboard for a station with batteries and feeders and a three-wire system.
17. What is your idea of the advisability of earthing the secondary in transformer systems?
18. What is the construction of an ohmmeter?
19. Why does an electromagnet spark on breaking the exciting circuit?
20. How are the pull and self-induction of an electromagnet connected?
21. A condenser having a capacity of two microfarads is connected to two terminals maintained at 2,000 volts; how much work is taken from the terminals, and how much can be got out of the condenser again?
22. What magnetic quantities are denoted by the symbols H, B, and μ; and how are they related to one another?
23. Given a ring armature 10in. long, 10in. diameter, 1in. radial thickness of iron, what wire would you use to give 110 volts, and what current would be suitable? Speed, 1,000 revolutions per minute.

HONOURS GRADE.

Candidates for honours must have passed in the ordinary grade. They may select their questions from one only of the following sections:

Section I.—Electrical Instruments, etc.

Answer questions Nos. 1 and 16 of the ordinary grade, together with not more than *five* of the following:

24. Compare the merits of the suspended coil (or Deprez) and the needle (or Thomson) galvanometer.
25. What metals or alloys are best for resistance coils, and what for the coils of voltmeters? Give reasons.
26. Describe Heaviside's, Thomson's, or any other good method of measuring very low resistances.
27. How would you test or check a differential galvanometer?
28. How would you calibrate a ballistic galvanometer, a known E.M.F. being given?
29. What is the potentiometer method of measuring (*a*) pressures and (*b*) currents?
30. What errors would you look out for if you were given a voltmeter to report upon?
31. How would you make a wattmeter for alternate-current work?
32. What are the relative merits of (*a*) hot-wire, (*b*) electrostatic, and (*c*) solenoid and core voltmeters for 100 and for 2,000 volts, alternating and continuous?
33. Describe critically any form of alternate-current supply meter with which you are acquainted.
34. Sketch a set of apparatus and connections suitable for the calibration of commercial instruments.
35. What is a dial bridge, and how are its coils connected?

Section II.—Dynamos, Motors, etc.

Answer questions Nos. 3 and 12 of the ordinary grade, together with not more than *five* of the following:

36. Design a transformer to give 50 amperes at 100 volts on a 2,000-volt circuit, 100 periods per second being taken as the frequency.
37. Give a hand-sketch of a tramway motor. What is the rated power of the motors generally used in tramway work?
38. What are the advantages, or the reverse, of single-limb magnets in small and large drum and ring machines.
39. Why is it more difficult to insulate a drum than a ring armature?
40. Draw a curve showing relation between a magnetic flux and the excitation in an ordinary low-voltage dynamo; and state what excitations would be suitable for a shunt, a compound, and a battery-charging machine.
41. Describe any safety devices for transformer circuits that you know of, and say how far you think they are really useful.
42. What are the merits and drawbacks of "hole" wound armatures?
43. Give your idea of the difficulties encountered in the design and construction of a good alternate-current motor.
44. Explain the action of a double-circuit, or two-phase (as it is sometimes called), motor.
45. What are the respective merits of steel, wrought iron, and cast iron for dynamo field magnets?
46. Why is the drop of a transformer greater when the secondary has self-induction in circuit?
47. Should a choking coil have an open or a closed iron circuit? Give your reasons.
48. Describe the best methods of testing large machines with small driving power available.

Section III.—Lighting and Power.

Answer questions Nos. 14 and 16 of the ordinary grade, together with not more than *five* of the following:

49. Given an engine and dynamo, how would you test the combination as regards steam consumption and output?
50. What are the advantages and drawbacks of parallel running in high-pressure alternating systems?
51. Why are arc lamps run off 110-volt circuits with resistances in series with each pair, instead of off lower pressures without the resistances?

Digitized by Google

52. What are feeders? Give a sketch of the switching arrangements in a transformer sub-station where there are several 50-kilowatt transformers and a three-wire secondary system.

53. Give your idea of the chemical action in an accumulator.

54. Describe one or two systems of street mains for low-pressure and high-pressure distribution.

55. Describe critically a continuous and an alternating current meter.

56. How does the probable load diagram influence the choice of a system for a given town?

57. Describe the kind of transformer used in a system for distributing two-phase currents.

58. In what way is the potential drop in mains affected, in alternate-current work, by (*a*) the frequency adopted for the currents, (*b*) the proportion of motors in use, (*c*) the design of the transformers used?

THE THEORY OF ALTERNATING CURRENTS.—IV.

BY A INST.E.E.

§ 11. **Definitions.**—As already intimated, we shall frequently find it necessary to make use of the sine curve (§ 9) in representing graphically alternating E.M.F.'s and alternating currents. In fact, such representations are so important that we shall now define certain geometrical terms associated primarily with harmonic motion, but which now are everyday expressions in alternating-current literature. At this stage we shall restrict ourselves to the terms intimately connected with sine curves, and introduce the few remaining terms when we require to use them.

Periodic Changes.—A set of operations which are repeated in exactly the same manner, in successive and equal intervals of time. Both alternating E.M.F.'s and currents are periodic changes, and we shall treat them as periodic E.M.F.'s and periodic currents which have the sine law.

Sine Curve.—A curve such that the successive values of consecutive points on the curve with respect to time, vary as the sine of an angle proportional to the time. Fig. 7 depicts the curve for an alternating E.M.F. induced by a simple loop, rotating in a uniform magnetic field, as considered in § 7, and, as already explained, P p measures the E.M.F. induced at the instant denoted by p. In other words, P $p = E_\theta$, and $E_\theta = D \sin \theta$, which is the equation to a sine curve. $x\,x'$ is the time line on which intervals of time are marked. θ is the phase as defined below.

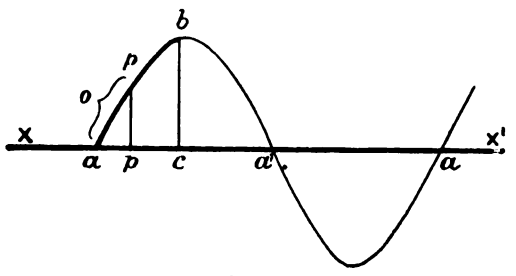

Fig. 7

Alternations.—The changes in the direction of an alternating E.M.F. or current. The part of the curve $a\,b\,a'$ represents an alternation in the positive direction.

Cycle.—A complete set of changes produced during one revolution of the loop. Each cycle consists of two alternations, and is represented by the curve $a\,b\,a'\,b'$.

Periodic Time or Period.—The time taken to complete one cycle. The length $a\,a'\,a$ on the line $x\,x$ denotes a period.

Frequency or Periodicity.—The number of cycles completed in a second; in other words, it is the reciprocal of the period, and is symbolised by the letter f, or the symbol $\sim\!\sim$. If the periodic time is T, then $\sim\!\sim = \frac{1}{T}$. If p = number of pairs of poles, and n = revolutions per minute, then $\sim\!\sim = p\,n/60$. In practice, the number of complete cycles varies from 25 to 130.

Amplitude. — The maximum perpendicular distance between the zero line and the curve $b\,c$ is the amplitude of the curve in Fig. 7.

Phase.—The fraction of a period which has elapsed since the rotating loop (armature) was in the position of zero E.M.F. in the positive direction. Both θ and $a\,p$ denote the phase of the point P, since $a\,p$ is the same fraction of the period, $a\,a'\,a$, that the angle θ is of four right angles.

§ 12. **Mean or Average Values.** — In the E.M.F. curve (Fig. 7) the maximum value is indicated by the length of $b\,c$, but since an alternating current varies in strength from instant to instant, and has values varying from zero to its maximum, it is evident that $b\,c$, the maximum value, is not the measure of the effective pressure sending the current through the circuit. We thus require other expressions, the most important of which is one that corresponds with an unvarying E.M.F. sending a steady current, which produces the same heating or dynamical effects whilst traversing a conductor without self-induction and capacity, as an alternating current produces in the same interval of time, whilst passing through the same conductor. In what follows, the maximum instantaneous values of E.M.F.'s and currents will be denoted by E_{max} and C_{max} respectively; and any other instantaneous values will be denoted by E_θ and C_θ, θ being the phase or the position of the revolving coil.

And since the quantity of electricity passing along a conductor, as well as the work done by the current, is not proportional to the maximum value of the E.M.F., we must now distinguish between three different values:

(1) The maximum instantaneous value;
(2) The mean value, or average;
(3) The effect value;

in terms of which the magnitude of alternating E.M.F.'s and currents may be stated: and, further, since these values bear fixed ratios to each other, it is necessary to determine and state what the relationships are which exist between them, and here it will be well to point out that whatever is true respecting the various relationships of the above values of alternating E.M.F.'s will be true for similar relationships between the resulting alternating currents so long as they obey the sine law, which we shall assume to be the case throughout these articles. Bearing the above statement in mind, we shall determine the ratios between the above three values of alternating currents.

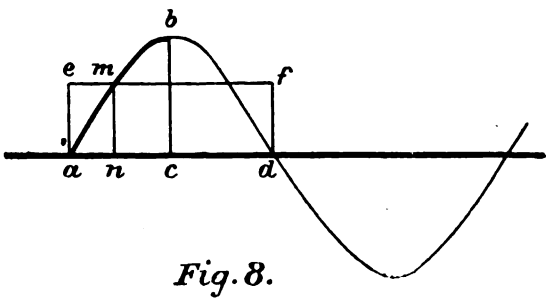

Fig. 8.

An alternating current obeying the sine law is represented graphically by the curve in Fig. 8, and, as before, the value of any point on the curve is given by the equation $C_\theta = C_{max} \times \sin \theta$. The maximum value has already been considered, so that we now shall pass on to consider the mean or average value. It is clear that if we divide a period into a large number of very small and equal parts that we shall get a series of increasing values for the current strength corresponding with every division, and if we erect at each division an ordinate, the lengths of the ordinate, and hence the value of the current, will be given by the equation $C_\theta = C_{max} \times \sin \theta$, in which θ is the phase corresponding with the individual divisions. The arithmetical mean or average value of such a series can be proved to be $2/\pi \times C_{max}$. This is shown by the length of the ordinate, $m\,n$, or the height of the rectangle, $a\,e\,f\,d$, in Fig. 8; and it may be mentioned here that the area of the rectangle, $a\,e\,f\,d$, is equal to the area enclosed by curve $a\,b\,d$ and the base line, $a\,c\,d$. Since $2/\pi = \cdot 6369$, or $\cdot 637$, $\cdot 637 \times C_{max}$ is the value of the equivalent continuous current which conveys the same quantity of electricity through a circuit without induction as an alternating

Digitized by Google

current, the maximum value of which is C_{max}, does in the same period of time. This value we shall call the *true mean value*. Similarly, the true mean value of an alternating E.M.F. is ·637 E_{max}. In future, E_m and C_m will denote the true mean value of an alternating E.M.F. and current respectively.

§ 13. **The Effective or Virtual Value.**—The true mean value just found, however, is not of much practical importance, since the light produced in an incandescent lamp, the heat produced in a wire, and the work done by a current is proportional to the square of the current passing. And, further, it is necessary to use instruments depending on the heating effects or electro-dynamic attractions and repulsions to measure alternating E.M.F.'s and currents, and these depend upon the square of the current. Thus the Cardew voltmeter is used to measure alternating E.M.F.'s, and, as is well known, the number of units of heat, H, generated by a current of C amperes in a time t is given by the equation $H = C^2 R t \times ·24$. Now, to obtain the value of an alternating current which is equivalent to a continuous current producing the same amount of heat, we must determine the mean of the squares of the current given by the ordinates for each division mentioned above, and the mean of the series of squares given by the equation $(C_\theta)^2 = (C_{max} \sin \theta)^2$, the phase, θ, varying between 0deg. and 90deg., can be proved to be $\frac{1}{2} . C_{max}^2$ or $·5\ C_{max}^2$. This is the effective value, or, as it is generally termed, the virtual value, which we shall denote by C_v, so that $C_v^2 = ·5\ C_{max}^2$, or $C_v = C_{max} \times \sqrt{·5} = ·707\ C_{max}$. The virtual value of a quantity, current or E.M.F., obeying the sine law is the square root of the mean of the squares of the instantaneous values. For the sake of brevity, this long expression is usually written $\sqrt{\text{mean square}}$. Since

$C_v = ·707\ C_{max}$, we get $C_{max} = C_v / ·707 = 1·414\ C_v$, from which it is clear that an alternating current, the maximum instantaneous value of which is C_{max}, generates H units of heat in the wire of a Cardew voltmeter, and by noting that H units of heat are generated by a continuous current of C amperes, we get the following definition:

An alternating current of one ampere is such that the heat developed by it in passing through a non-inductive resistance is the same as would be developed by a continuous current of one ampere strength passing through the same resistance in the same time.

Similarly the virtual volts, $E_v^2 = \frac{1}{2} E_{max}^2$ and $E_v = ·707\ E_{max}$, from which we see that the alternating pressure which produces light in an incandescent lamp, or readings of a Cardew voltmeter, is ·707 of the maximum pressure. In other words, the light, or deflections produced, indicates a pressure equal to 70·75 per cent. of the maximum pressure. The following example of an alternator will help to make the matter clear: A Mordey alternator (75-kilowatt size) supplies 37·5 amperes at 2,000 volts to a certain circuit. The frequency is 100. The maximum E.M.F. generated is 2,000 × 1·414 or 2,828 volts, so that the E.M.F. generated by this machine changes from 2,828 positive maximum volts to 2,828 negative maximum volts 100 times per second. In other words, 2,828 is the value at the peak of the wave, and 2,000 the virtual or effective voltage.

The relation between the two mean values thus found is as follows:

$$\frac{\text{The virtual values}}{\text{The true mean values}} = \frac{·707\ E_{max}}{·637\ E_{max}} = 1·1, \text{ or } E_v = 1·1\ E_m,$$

that is, the virtual value is 10 per cent. greater than the true mean value. In practice, we have only to deal with virtual volts and virtual amperes, but it must not be forgotten in designing alternators, specifying conductors, and constructing measuring instruments, that in all cases the insulation must be such that it will stand a pressure equal to the maximum instantaneous value.

Let us now consider one or two numerical examples.

(1) A cable for continuous currents was insulated for 500 volts. What is the highest virtual pressure of an alternating current for which this cable is suitable?

Since $E_v = ·707\ E_{max}$,

and $E_{max} = 500 . \therefore E_v = ·707 \times 500 = 353·5$ virtual volts.

(2) A Siemens dynamometer indicated that a current of 30 virtual amperes was passing through a circuit. What quantity of electricity was passing per second?

Since $C_v = 1·1\ C_m . \therefore C_m = ·9\ C_v$,

and $C_v = 30 . \therefore C_m = ·9 \times 30 = 27$ amperes per second.

(To be continued.)

OPPORTUNITIES IN ELECTRICAL ENGINEERING.*

BY A. A. ATKINSON.

Papers have frequently been published in the electrical journals deprecating the over-popularity of the electrical business in its various phases, claiming that the profession is already overcrowded, and upon this ground offering discouragement, sometimes in very strong terms, to the aspiring engineer.

It is only fair, of course, that an attempt be made to present the other side of the question. To this end this paper is written. For I cannot help seeing much encouragement in the outlook. Everything considered, I find electrical engineering in the broad acceptation of the words, if not on a flattering, at least on a very favourable basis as compared with other professions in regard to attractiveness, educational value, and money return. In this it will be apparent that I am not at all Malthusiastic. I believe there is room and to spare.

Why should young men be discouraged from preparing themselves in a business and an electrical way to take charge of lighting stations and power plants, or any other practical applications, "because the growth of this business is not likely to be either sudden or rapid, or the opportunities offered particularly brilliant"? Should we say to the young man that has the aptitude and inclination for something else, "stay on the farm, or in the shop, or in the store at 25dol. or 30dol. a month, because if you go into the electrical business, for instance, you cannot get more than 40dol. to 60dol. a month"?

Is it any more of an argument for the opposition to state that "the electrical railways at present do not seem to appreciate the need of trained men, and most of them are satisfied with their horse railway superintendents who have picked up enough of electrical information to make the cars run whether a dividend is paid or money sunk"? The statement refutes itself, for it certifies to the very conditions that do demand the right kind of men. Let the men proper prepare themselves and prove their necessity to owners of electrical stock. The only reason that such a condition exists is on account of the paucity of the men who are able by training to bring the business out of its present status. These and similar positions are not open to the merely technical and high-priced theorists. They belong to those who have been advised in the course of their instruction of the exact conditions and practically prepared for what is, not taught to expect big salaries and find or make positions to suit them. One of the things I also believe that often cast discredit upon the value of a college preparation is the lamentable failures of some technical graduates in attempting to manage practical electrical matters. And these conditions are not at all fanciful. Just such bad management is very easy to find in lighting and in power transmission in all too many places. Just these conditions are the argument for better men trained for the right thing.

I grant that there are too many who enter the profession with the purpose of "making their mark'—just the kind that are most apt to meet with failure. But as much can be said of any profession under the sun. I believe, also, that as the term "electrician" ought to be understood—not the electric bell and annunciator fiend—but few are needed. I grant again, that many applications are being refused by manufacturing firms—they themselves even failing and going out of business. Granted that many classical graduates enter engineering schools to swell the ranks of that profession. All this admitted, I still contend that there are abundant opportunities for the pushing men who understand their business. Leaving out of consideration for the

* From *Electricity*, New York.

Digitized by Google

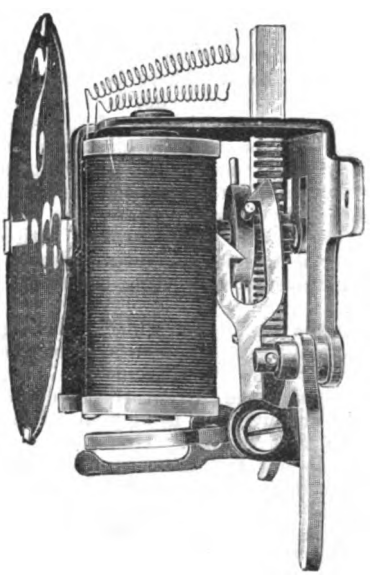
present the character of the positions offered in the various lines of professional and practical work, and looking only at the numbers studying for engineering in one or two instances, I know personally that in one or two institutions whose catalogues were quoted by Mr. Floy to show the great number of students of engineering, at least six to eight times as many are at the same time registered in the law departments alone, to say nothing of the medical and other professional departments, aside from the single professional schools in cities everywhere. Even if we should admit that only one-eighth as many men are required in the varied lines of electrical work as in the legal pursuits, still we are on favourable ground, with not the least reason to deprecate the number.

The value of the electrical engineer, and hence his success in the business undertaken, will depend on three things—namely, natural ability and aptitude of the individual, the character of his course of training, and the general view of the situation with which he leaves college. And this will lead us to consider the relative advantages of a purely technical and a practical education. Of course, the third condition of success may result from either of these. But before undertaking either course the individual must satisfy himself by a study of his proclivities, so to speak, whether he has any ability and inclination in the direction of electrical engineering. He need not enter the profession for money or fame if he does not like to work out the course, practice, and theory, almost as well as to eat. Certainly, if he study only for the mental discipline and for a personal knowledge of the subject, this would not be true to the same extent. Or if his desires run toward business, law, medicine, sport, or idleness, he will not succeed as an electrical engineer. But supposing that we have to deal with those only who should properly be engineers, so far as opportunities in life suggest, what kind of course shall be selected?

(To be continued.)

NEW INDICATOR MOVEMENT.

A new indicator movement, an illustration of which we give herewith, has been brought out by the International Electric Company, of 55, Redcross-street, E.C. They call it the triplex movement, and it allows of three different signals being given with the same movement.



It is constructed on the principle of their "Universal" bell, described in the *Electrical Engineer* of July 27 last. While hitherto a prearranged code of signals has allowed of making use of the same bell to give different signals and to call different people, the want of a recording instrument that would show correctly the number of calls has been felt.

The "Triplex" movement records permanently (until replaced) who has been called, so that when the bell has been rung once, twice, or three times, each different signal attached to the same movement will appear consecutively and remain visible. Indicators fitted with this movement could with advantage be used on board ship in the ordinary way, as the "Triplex" has a locking arrangement, which only drops when a current is passed, and is not in any way affected by the rolling of the ship, even in the severest weather.

ALTERNATING AND INTERRUPTED ELECTRIC CURRENTS.*

BY PROF. GEORGE FORBES, M.A., F.R.S., M.I.C.E.

LECTURE III.

Sometimes at the close of a lecture the lecturer finds that he has miscalculated his time, and has to hurry through things more rapidly than he intended, so I shall begin by saying a few words which I should have said at the end of the previous lecture but for the reason just stated. In the course of these lectures I have been able to show you some interesting experiments in different branches of electricity, and also certain curious phenomena connected with them. I wish, in the first place, to say that in all these experiments there is nothing original or new—that they are simply illustrating well-known principles; and, secondly, that I have to express my great indebtedness to all those who have assisted me in the matter—and especially I feel that I owe a great deal to Mr. Campbell Swinton, who has put at my disposal this induction coil and much of the apparatus which you see before you, some of which I shall be using to-day. I wish, also, to express my indebtedness to Dr. Alexander Muirhead for the use of the different illustrations in the matter of the submarine cable, and also to my assistant (Mr. Mitchell), Mr. Stanton, and Mr. Edgar, who have made the work of preparing these lectures quite contrary to what it usually is—a pleasure instead of a labour.

If in any of the illustrations that I have given you of the analogies between electrical phenomena and mechanical phenomena I have introduced anything different from what you have been accustomed to, it is simply a natural interpretation of the mathematical formulæ that represent the phenomena. Mathematics applies equally well to mechanical phenomena and to electrical phenomena, and it seemed to me a suitable thing not to use mathematics to illustrate electrical phenomena, but to use mechanical phenomena to illustrate the electrical.

Now about these analogies which I have used. I wish to impress upon you before we part that there is more in these analogies than the mere rough resemblance which I have tried to point out to you in the course of these lectures. and those who are more deeply interested in the applications of electricity will easily see that there is room for a great deal of thought in carrying out these analogies, and making clearer in their minds the processes which are going on in certain electrical phenomena.

In the table which I showed you last lecture I gave you an example of the methods of measuring the actual units when we are using the torsion of any rod or other mass to represent electric currents, and I wish to say that if in the case of any electrical problem occurring to an engineer—such, for example, as the propagation of electricity along a cable from Niagara Falls to Buffalo—if he wishes to see whether troubles will arise in the electrical phenomena, if he will make an imitation cable on the lines of assuming those units which are in the table, he will be able to imitate the action of what goes on in the real cable, and he will be able to see whether any peculiar mechanical effects are produced, and to trace their analogy with the electrical effects, and so be able to see what kind of troubles he is likely to meet with. And this I consider to be a matter of very great importance, and it was with the object more of throwing out suggestions than of working out the analogies in a complete form that I introduced them in the present course of lectures. The working of them out in a complete form would not have been a suitable subject for these lectures, but I hope I may have time on another occasion to work some of these analogies out more fully, and so to render some assistance to those who are engaged in such work.

In the first lecture I was dealing chiefly with capacity and the influence which it has upon alternating or interrupted currents, and the most interesting illustrations of the effects of capacity were naturally found in the submarine cable. Last lecture I was dealing chiefly with self-induction, and I showed you that there were certain troubles which were likely to arise in any case in which we used self-induction, and I explained to you that this would be the case with other kinds of currents, whether we are using continuous currents or alternating currents; that in either case if you have much self-induction in the circuit, by breaking the circuit you are able to get far larger E.M.F.'s than what you are impressing upon the system, and these may be destructive to the insulation of the system. The only difference is that in the case of alternating currents, the self-inductions that we have in the transformers are enormously greater than those when using a continuous current; and, therefore, the importance of this question becomes clearly greater in the practical application of alternating currents, and especially in the practical application of them on

* Lecture delivered before the Royal Institution.

Digitized by Google

a gigantic scale as in the case of the utilisation of the Niagara Falls, where the transformers are of enormous magnitude and the self-induction very great indeed. In such a case as that it would be, I might almost say, criminal to suddenly break the circuit, the danger would be so great.

Now, to-day, passing from these two subjects, I am going to deal with three other peculiarities which arise in the transmission of electric currents, especially alternating or interrupted currents—skin resistance, resonance, and oscillations. All of these are interesting phenomena from a purely scientific point of view, and are of far more importance from an engineering point of view. I mentioned in the course of the last lecture that a great many of these difficulties in the engineering problem can be got over by reducing the frequency of the alternations. When I first reported to the people who are utilising the Niagara Falls in the year 1890, now some five years ago, as to the proper means of utilising them, I urged the adoption of the system we are now introducing; and on noticing those various troubles that might arise I gave the best solutions of them that seemed available. Since that date the enormously valuable suggestion occurred to me of the lowering of the frequency of the alternations, and that, together with the other precautions that have been introduced, has taken away all the danger of any trouble that we might otherwise have expected from the use of alternating currents with such a system.

When we come to very high frequencies, these effects are greatly increased; and by means of Mr. Campbell Swinton's apparatus which I have been employing I have been able to get very high frequencies indeed. By using an oscillatory discharge (about which I shall speak more fully later on) which oscillates at very rapid frequencies, and also by using high E.M.F. in this discharge, I am able to get effects which could not be got by an ordinary alternating current. At the same time, by observing the effects with these very high frequencies we are able to grasp what is going on at the lower frequencies, though not to such a serious extent.

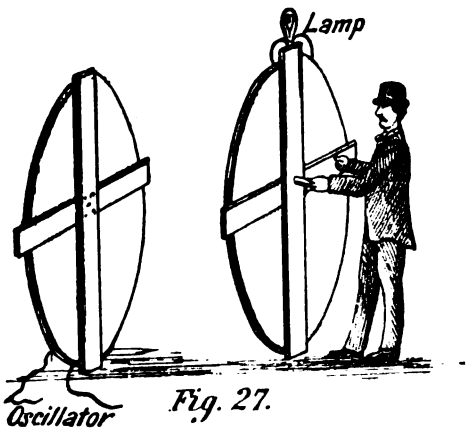


Fig. 27.

I will now show you the effects of mutual induction between two circuits which can be obtained by means of very high frequencies and by very high electrical pressure—great voltage. I am going to employ the two copper wire hoops (Fig. 27), measuring about 6½ft. or 7ft. in diameter, which are standing in front of me, and I am going to pass through one of them an oscillatory discharge of very high frequency indeed and of very high electrical pressure. Now, everyone who is accustomed to seeing cases of mutual induction will be perfectly well aware that if we are simply passing an alternating current through one of these wires, it would be impossible to induce much force in the other wire. I wish to show what a considerable amount of power can be developed when the E.M.F. is sufficiently high and the frequency sufficiently great. And that is what we are doing when we use the oscillatory discharge of Mr. Campbell Swinton. I take away from the apparatus one of the hoops, to which I have attached an incandescent lamp at the top. I will immediately cause a high-frequency oscillatory discharge to pass round the other, and I wish to show you that even at a considerable distance the current which passes through the wire which I am holding is sufficient to light the incandescent lamp at the top. [*Experiment.*] At the present moment the illumination is not visible. I approach the hoop nearer to the coil. At this distance it is very dull indeed, but still perceptible. I now approach to within a couple of feet, and you see it rises to its full brilliancy. That is simply due to the induced current which is going round this wire of a diameter of 7ft. I can twist it round in different directions, almost at right angles to the fixed one, and still get a certain amount of illumination, but when it is completely at right angles it goes out. When I turn round again and the two wires are once more parallel, the brightness is as great as it was before.

Now, I intend to take some of the same apparatus which I have been using here to show you another very remarkable effect of these high-voltage experiments. When we use very high electric pressures we require a much smaller current to produce the energy which lights up an electric lamp, for instance; and if we send very high electric pressures through a lamp with intervals of rest, when the current is not passing, we are able to produce a very large current for a small fraction of time, after an interval another very large current, and on the whole the total quantity of electricity which has passed through to produce the lighting of the lamp will not be so great as the total quantity which would have passed through if we had had an ordinary continuous or alternating current passing through the lamp. The effect which takes place on the lamp is measured by the square of the current. Let us take two cases—first, of a lamp and the current continuously going through it; we have a certain amount of electricity passing through the lamp; in the second case, if we pass it for one-tenth of a second each second of time and pass 10 times as much current through it we would get 100 times as much effect during that tenth of a second: therefore, you would get 10 times as much effect on the whole It follows, then, that when we increase the maximum current during a short period we are increasing the energy which is supplied to the lamp during that period far more than we are increasing the current. It appears, therefore, that by acting in this way we are able to pass a far smaller sum total of current through the lamp and yet to get the same amount of energy consumed in the lamp. This is probably the reason why an electric lamp can be lighted through a person's own body, as is possible with such apparatus as is before you. The amount of current which I am able to stand without injury from hand to hand is certainly less than 1-100th of an ampere; and if I can show that a lamp can be lighted through my body, I know that there is not in the energy more than 1-100th of an ampere passing through the lamp, and yet if I bring the lamp up to incandescence—a lamp that ought to require one-fifth of an ampere—I must assume that the energy is the same, but that the total quantity of electricity is not the same; and that is what I wish to show you is the case in the experiment. Now, this is an experiment which everybody does not like to try, so I will ask Mr. Campbell Swinton, who has

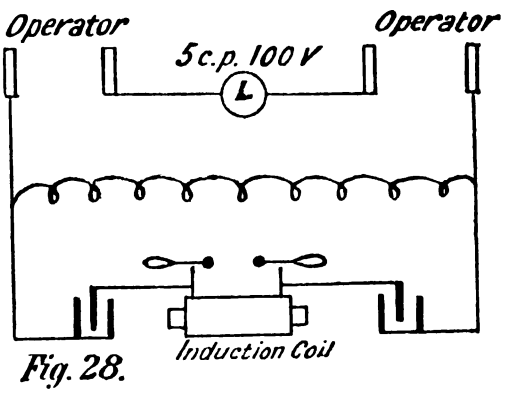

Fig. 28.

arranged the experiments, if he will assist me in taking the current through the body. There is really not the slightest trouble, or danger, or inconvenience in doing it. I showed you in the first lecture some experiments of the same sort. There it was perfectly obvious that the electricity was not passing through the body which was lighting the lamp, but in this case it is perfectly obvious that the electricity is passing through the body (Fig. 28). [*Experiment.*] Now, the electricity coming from that coil is certainly going through both of our bodies, and we can lower it to any amount we please, or raise it up to its full incandescence, by cutting out more or less of the impedance coil.

Now, whether the explanation which I have given you, and which Mr. Campbell Swinton supports, is the complete explanation or not I cannot tell you. It seems to go a long way towards explaining it. Passing the current through the body is a very different thing to receiving it, using yourself as a Leyden jar, as I did in the first lecture. There, there is no sensation whatever; you do not feel the current at all. In this case both Mr. Campbell Swinton and I felt the current passing through our bodies—and it was nearly as much as one cared to take comfortably, and one feels a certain amount of warmth, but I do not think that that is the true calorific value which is imparted owing to the energy used up in one's body; but it certainly does warm one.

I now wish to introduce to your notice a subject which has attracted considerable attention during the last eight or nine years in the use of alternating or interrupted currents. I speak of what has gone by the name of "skin resistance." The fact has certainly been proved—and it could not be otherwise, from the mathematical treatment of the question—that when we pass a high-frequency alternating current through a conductor the flow of current is not uniform throughout the section of the conductor. It is, partially at least, confined to the exterior layers of the conductor. At the centre there is not so much

Digitized by Google

current passing as there is through an equal section of the outside, and therefore the resistance of the conductor is composed more of the resistance of the external parts than of the central part, because if we make the frequency high enough we can cause the current to cease flowing from the central part entirely. In that case, the material which is offering resistance is simply a tubular conductor and not a solid conductor. That is the meaning in which the term "skin resistance" must be read.

It was, I think, in the presidential address to the Institution of Electrical Engineers in, I believe, the year 1885, that Prof. Hughes first introduced this seriously to the notice of electricians. I do not mean to say that some of the effects had not been observed before, and I do not say that it was not known that there might be difference of flow in different parts of the section of the conductor, but that was the first date when this resistance was proved to consist of a pure definite resistance, and was measured in ohms as a resistance by Prof. Hughes. Up to that time people had been perfectly well aware that, in using the methods of the Wheatstone bridge, if you kept the key of the galvanometer, a deflection of which indicates divergence from the resistance, down, and interrupted the circuit, you could not get a true reading. Generally, this was ascribed to self-induction, which at the time of breaking the circuit with the electric battery made itself apparent, but which to a far greater extent, except when you are using coils, was often due to what Prof. Hughes showed to be really an increase of the resistance, and that increased resistance is due to the electric current being at the outside instead of being uniformly distributed through the section of the conductor which was carrying the current. Now, the explanation of this is not difficult to seek. You remember in the last lecture I had two wires of about 7ft. long parallel to each other. I passed an electric current through one, and at the moment of making that circuit the other whose circuit was completed through the galvanometer showed an induced electric current, and at the moment of breaking the primary current the circuit connected with the galvanometer showed an induced current, but in the opposite direction to that previously exhibited. Thus,

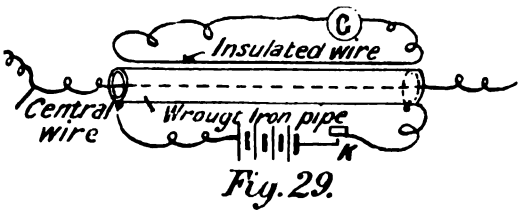

Fig. 29.

in an interrupted current, at the moment when a change in the direction of the electric current takes place, there is a reverse effect due to mutual induction. Now, suppose that this rod on the table (which is merely for illustration) consisted of a bundle of wires, and I insulated and separated out the central wire, and also insulated and separated out one of the external wires, and then sent through the whole bundle an electric current, there will be an induction current in either of those which I have selected and insulated; there will be in those an opposing E.M.F., a force tending in the opposite direction to that in which the primary current is going. But if you will notice the position of all the wires in the bundle relatively to one of them on the outside, and also notice the position of them relatively to the central wire, you will see that the central one has far more wires within a short radius of it than the external one has. Therefore the opposing force on the central wire is much greater than the opposing force on the external one, so that, when I suddenly pass an alternating current through a bundle of wires, at each change in the direction of the current there is an opposing force in both these wires, but the opposing force in the central wire will be much greater than that in the outside wire. That is to say, there is an opposing force in each of the wires of the bundle, but a greater opposing force in the central part, and therefore the current will not flow so powerfully there as it does at the outside. If, therefore, we have the whole bundle grouped into a solid conductor, the central line has always an opposing E.M.F. which is greater than the opposing E.M.F. at any other portion of the section. Therefore the current is mainly passing through the external part of the conductor, and that causes an increase of resistance, which was actually measured by Prof. Hughes by means of the ingenious apparatus he produced on the occasion to which I have referred.

Now, here is a brass tube with which, however, it would take some time to show you the effect, because it needs a very sensitive galvanometer, and it takes some time to bring it to rest. Prof. Hughes showed that the additional resistance produced by an iron conductor was much higher than a conductor made of any other material. Therefore, I will proceed by utilising an iron tubular conductor (Fig. 29) with a wire suspended through its centre and another insulated wire lying on its surface, and I wish to show you the different effects of induction in these two cases. I will begin with the outside wire, which is subjected to the induction at varying distances up to the diameter of the tube. There will only be a deflection in this case of two or three divisions of the scale on the screen, so you will please watch carefully and make the measurements for yourselves. [*Experiment.*] There, you see, it goes nearly up to the two divisions. I passed the current through this mass of iron, and the induced current on the outside parts of the wire was sufficient to deflect it through about one and a half divisions of the scale. Now change the connections, and you will see the great difference there is. [*Experiment.*] This time you see that the deflection passed along nearly the whole length of the scale. That is the deflection obtained with the wire which passes through the centre of the tube, showing the enormous difference of the E.M.F. in the two parts. This enormous effect in the case of the iron is due to the fact that the iron becomes magnetised by the passage of the electric current through it. It becomes circularly magnetised—lines of force cut the wire which is suspended in the middle of the tube, and in cutting it they exert a force greater than the E.M.F. that there would be if there had been no iron, which is easily magnetised, or if the iron had been replaced by copper, through which you cannot get so great an amount of magnetism so easily. This illustrates the general principle of skin resistance. I may say that in actual practice an engineer is seldom troubled with this except when he is coming to very large works where the cables are very thick indeed. With all the cables that we have been accustomed to in industrial work in this country there should be no trouble whatever; and it is only when you come to cables of 1in. or 2in. in diameter that the trouble would come to be serious. But when once you lower the frequency as we have done on the other side of the Atlantic, this trouble disappears entirely. Up to any size that we wish to use for our conductors there, there is not the slightest trouble from the extra resistance produced in this way.

(To be continued.)

ON THE RECENT DEVLOPMENT OF THE SINGLE-ACTING HIGH-SPEED ENGINE FOR CENTRAL-STATION WORK.*

BY MARK ROBINSON, MEMBER.

(Concluded from page 572.)

A discussion upon the economy of the single-acting engine should include running expenses other than steam, but this would greatly lengthen the paper. Moreover, it is only users who can pronounce upon this question finally and with authority. That single-acting engines of the closed type are very economical in oil is generally allowed, and economy in attendance is also conceded. An engine which oils itself cannot want much looking after. Repairs are the only point which really admits of dispute, and these are dealt with under "durability" in the succeeding paragraphs.

Durability (*b*).—The idea that because a machine makes many revolutions a minute it must wear out more rapidly than a slow-running machine, seems to have the force of an axiom for some minds. Yet there is nothing axiomatic, nor even, to the instructed, probable about it. In the first place, high speed is a very winnowing fan, in the matter of workmanship. It is surprising what a slow-speed engine can endure for a season in the way of bad workmanship; but not so the high-speed engine. If it will run at all, there is probably no reason it should stop, so far as workmanship affects the question. In the next place, the piston speed is usually much lower than in slow-running engines, owing to the short stroke—about 525ft. a minute is the highest piston speed in any single-acting electric light engine. The wear of piston rings and cylinders is bound—other things being equal—to be proportional to the piston speed, and this applies also to valves and glands. In one important point, however, other things are not equal, but are largely in favour of the single-acting engine. The system of packing rings previously described, which cannot be used in double-acting engines without much complication, has decisive effect upon cylinder wear; and even if one went back to the records of the old vertical beam engines, which used steam at 30lb. per square inch and have been described as "revolving occasionally," it may be doubted whether such evidence of good wear could be found as is now to be quoted in favour of the fastest-running engines.

The makers of the Willans engines have for some years past lost no opportunity of obtaining and recording exact measurements of wear, where they have been called in to carry out overhauls or examinations. The results are systematically recorded, and they show, speaking generally, an absence of

* Paper read before the Institution of Electrical Engineers, May 9.

Digitized by Google

wear beyond all claims made or expectations formed by those interested in the engine. On March 9, 1895, a G G, or 80-i.h.p. compound non-condensing engine, No. 906, used for lighting one of the largest hotels in London, and stated to have run (at about 400 revolutions per minute) for 14 hours per day, including Sundays, was taken down for overhaul, never having been so much as taken down for examination since its erection in April, 1890—that is, five years previously. The report states that "all the parts were carefully measured, and the H.P. and L.P. trunks showed no perceptible wear, and were replaced the same as they were taken out. On measuring the H.P. cylinders, we found they were 2-1,000ths of an inch larger than our standard size, and the L.P. cylinders were the same; still they were quite round. All piston rings and gland rings were replaced without any repairs whatever. The whole of the repairs to this engine, including taking down and re-erecting, were executed in 24 hours."

It will be justly said that if such a report reflects great credit upon the engine, it reflects no less credit upon the engineer who has charge of it. The constant and heavy work in this case is no real disadvantage: the chances of corrosion during stops of a few days are more injurious. In a lighting station where work is more intermittent, and where during the summer engines are liable to be laid off for comparatively long periods, the wear (or corrosion) is greater, and the following is an instance of what is looked upon as heavy wear under such circumstances. The engine is of H H 12 size, No. 999, being of an exceptional type—that is, having 12in. stroke instead of 8in. (as usual in H size), and running under 200 revolutions instead of at about 380; it was one of a pair ordered to a special specification, and from the point of view of objectors to high speed it should give good results. It was erected in March, 1891, at one of the London electric lighting stations, and in February last it was taken down for an ordinary overhaul, and was re-erected. As the condition of the engine was manifestly good, and as it was non-standard, so that information about it had not the usual value, it was not measured, but hearing that a visitor to the station had measured the high-pressure cylinders while lying about, and had stated them to be much worn and considerably oval, the makers, though certain that the statement was a mistake, asked permission to take the engine down again, and made unusually full measurements checked by more than one observer, in the presence of the chief engineer of the station. It appeared that in one cylinder, though the ovalling ranged only from 2 to 7-1,000ths, there was in one part wear (in four years) of 28-1,000ths, or nearly 1-35th part of an inch; the other cylinder showed about half this wear, and no ovalling.*

The third instance is of an engine working under really good conditions—that is, driving a cotton mill, and working therefore for long hours, and with scarcely any stops exceeding two days. This engine, No. 1,253. of 650 i.h.p., commenced work in April, 1892, and though the cylinders had been taken down before, they had not been closely examined or measured. At Easter, 1895, it was thought desirable to have the engine closely examined, and between the Thursday evening and the following Sunday afternoon it was completely dismantled, thoroughly examined and measured over, cleaned, re-erected, and started under steam. There was no repair of any kind to be done, and but for the accidental breakage of some studs during re-erection it would have been running a few hours earlier. The report upon wear was most satisfactory, but the facts are best given in the words of the inspector sent by Mr. Michael Longridge, who supervised the examination on the part of the owners of the mill. This gentleman wrote: "The cylinders were taken down and pistons and valves out; the cylinders are 17in., 28in., and 40in., with 1ft. 6in. stroke. Revolutions, 206; boiler pressure, 160lb. I examined and gauged all the six cylinders with a very fine gauge, one that can be set to 1-10,000th part of an inch, and found H.P. cylinder about 1-1,000th part of an inch worn; I.P. cylinder 1-3,500th part, and L.P. 1-7,000th part of an inch worn; indeed, the tool marks had not properly worn out. The surfaces as smooth as glass. The pistons and rings seem to be very good, and the rings of the piston-valves also appear to be very good, all bearing well round; the piston-rods or trunks also appear to have good surfaces; also internal surfaces, where the valves work, seem good, and the rings of the piston-valves also appear very good, so that they scarcely appear to have been at any work. I must say that I never came across anything so accurately fitted together; even gauging the cylinders with the above-named fine gauge, I cannot say that I even found a slack place one way from another. Whether the engines are of good principle or not, the workmanship is good, which contributes to small wear and little friction. Crankshaft necks and crank-pins seem very good, being very smooth." "Whether the engines are of good principle or not" is valuable; clearly the giver of this emphatic testimony is no devotee of the single-acting engine. All brasses and journals, eccentrics, etc., were stated by the overhauling staff to be in perfect condition.

When the single-acting engine has run n years, it is always open to objectors to say (as they do) that no doubt it is good for n years, yet $n+1$ years will finish it. The argument admits of no refutation—that is, the present objectors may be right—for a year, though those of last year are refuted already. But reasonable men with such evidence as the foregoing before them will pay more heed to the counter-claim, which is, that the durability of the high-speed single-acting engine is not inferior to, but enormously exceeds that of the best double-acting engines, unless the latter revert to an archaic slowness of running, in which case their enormous size and cost will exclude them from practical consideration.

With many hundreds of single-acting engines at work, there are, of course, some cases of trouble. There have been broken crankshafts, though not in an unusually large proportion, if we exclude a succession of breakages in a single important station which attracted much attention. There were special reasons in that case which contributed to the result, but the plain and honest reason why the cranks broke (as with all other cranks which have broken since cranks began) is that they were simply not strong enough. The engines which formerly had a 4in. shaft have for some years past had 5in. shafts. The 4in. shafts have broken, and the 5in. have not, and are not likely to—apart from the effect of those occasional flaws against which no steel forging can be absolutely guaranteed.

Other cases of excessive wear, or of damage, when not referable to defective lubrication, may usually be traced to under-loading—*i.e.*, to running with so light a load that the pressure in the steam-chest becomes insufficient to hold down the lines of valves in constant thrust against the eccentrics. The single-acting engine has, of course, the defects of its qualities. Constant thrust is perfect so long as it lasts, but without it, the single-acting engine has no claim to admiration. For the pistons, and main moving parts generally, the question was settled once for all, so far as regards the Willans engine, by the well-known "air-buffers," which provide completely for cushioning, irrespective of change either of load or of back pressure, the distribution of the steam by the valves being absolutely untrammelled by any consideration of cushioning. Unfortunately, the air-buffers do not cushion the valves, and it is as important that the latter should be held closely down upon the eccentrics as that the connecting-rods should not leave the crank-pins. The line of valves is fairly heavy, and owing to the eccentric being seated on the crank-pin, though the stroke of the valves relatively to the ports is moderate, yet the total stroke is nearly as long as that of the pistons. "Holding-down power" is intended to be given by the pressure of the steam in the steam-chest upon the topmost valve, but if the pressure is too much throttled down, the "constant-thrust" element is wanting, and the parts have to be checked upon the up stroke, more or less, by the underside of the eccentric strap bearing against the sheave—a state of things which, at least in theory, is inadmissible in a constant-thrust engine. In practice, however, if there is good surface on the eccentric sheave, and a well-hardened pin at the small end of the eccentric rod, no serious results follow, provided the defect of pressure in the steam-chest is only occasional, and is not too considerable. Under such circumstances, however, it is necessary to look now and then to the eccentric straps, and take up the wear if necessary, and to be warned in time if the engine begins to run noisily. The lesson of the wastefulness of running an engine at light load, if it can possibly be avoided, has now been so well learned that in lighting stations at least (except, perhaps, in alternating stations where parallel running is not practised) there is little danger of the load, and consequently the steam-chest pressure, being allowed to fall low enough to jeopardise the "constant thrust" of the eccentric straps; but where such a probability exists it adds a reason for using variable expansion gear, which of course secures the maintenance of high pressure in the steam-chest. In a throttling engine it is also easy to secure the required holding-down pressure on the valves by forming the little steam-chest dome which tops each line of parts as a cylinder, in which the uppermost of the line of valve pistons works. The top of each little cylinder is in communication with the steam-pipe outside the throttl-evalve, and so gives a constant down pressure on the valves, irrespective of throttling. Of course these fittings cost something, and they need special lubrication, so that it is only in very exceptional cases that it is worth while to fit them, and in such cases there are probably other sufficient reasons for using variable expansion gear instead. It is well to bear in mind, however, that in special cases the durability of the valve motion may require to be secured by special precautions; it is not absolutely assured under all circumstances like that of the main working parts.

* The statement which gave rise to the remeasurement was that one cylinder was fully ¼in. oval, and that there was much tapering and wear generally. It was made beyond question in absolute good faith, probably from using inadequate or extemporised measuring appliances. The remarkable point was that the visitor was an engineer, and stated that he had been provoked to measure the cylinders by being told that no wear would be found in them, but that, "as an engineer himself, and accustomed to measure cylinders," he did not consider the wear, as he supposed it to exist, was excessive for the time the engine had been running.

Lubrication (*c*).—Where the parts of an engine lie permanently in the lubricant, both when running and when standing, the quality of the oil is of more importance than where it is used in the old-fashioned way. Free acid in oil, which is more common than is usually supposed, leads to corrosion, and in some few cases has caused serious trouble; the quest for a perfect crank-chamber lubricant which shall always be the same, is not quite ended yet. Cylinder lubrication has long ceased to trouble (if the user does not sacrifice everything to cheapness), but not so the other. Sometimes it would appear that acid is brought over in priming water from the boiler: in some cases it has been traced, with tolerable certainty, to special boiler compositions containing acids, which may find their way with priming water past the valves into the crank-chamber. The tests for acid, however, are comparatively easy, and its presence is soon shown by the rusty red colour which the lubricant begins to assume, and, in worse cases, by the condition of the parts. Prevention also is usually easy, as by the use of small quantities of soda, or of soft soap, added daily to the crank-chamber in very minute quantities: if there is much of it, it "lathers" so successfully that it drives everything else out of the crank-chamber. The "personal equation" enters much into this, as into other questions of engine management. There are many hundreds of closed engines running where trouble with lubrication has never been heard of, yet in a few, working apparently under identical conditions, everything is different. Where oil is of doubtful quality, temperature plays, or may play, an important part, and the advantage of keeping the crank-chamber cool has for some years been recognised. In the Willans engine cooling pipes are usually fitted in the crank-chamber, through which, if the engine works non-condensing, it is well to run a small stream of water. About one-fourth of the quantity which is supplied to the engine as steam per hour is generally enough, but it is sometimes a convenient plan to run all the feed water through. In a non-condensing engine the crank-chamber is hotter than in a condensing engine, because the main source of heating is conduction, by the walls of the crank-chamber, from the "exhaust-chamber" above. When the exhaust temperature is about 215deg., as in a non-condensing engine, the crank-chamber, of course, grows hotter than where the exhaust is at condenser temperature. 170deg. F. is a perfectly safe temperature for the crank-chamber, but the lower it is, the more one has, so to say, in hand; and it is such an advantage to have complete control over the temperature, that it is generally worth while to adopt the cooling pipes, even in condensing engines. The large ones are made, as shown in the section in the appendix, with a kind of water-jacket to the crank-chamber base. It is evident that the engines might be constructed with a more complete separation between the hot cylinders and exhaust-chamber, and the cool crank-chamber: there might, for instance, be an air-space and columns between those parts. But, as is true of many other possible minor improvements, the gain from this arrangement might be bought too dearly; it is cheaper to take easy precautions against small and infrequent troubles, than to make the engine larger and more costly, even if theoretically more perfect.

Vibration (*d*).—The increase of town-lighting stations gives great importance to this subject, but as it has recently been somewhat fully dealt with, as regards both engines for lighting stations and marine engines, in a paper contributed by the author jointly with Captain Sankey, R.E., to the Institution of Naval Architects, it is not proposed to treat it at length on the present occasion; it will suffice now to say only enough to show in what direction improvement is most probable.

In a recent well-known case, several single-acting engines, supposed to be remarkably free from vibration, have been removed from a London station and replaced by steam-turbines, as the only certain means of meeting the objections of persons living close by. What was the cause of the vibration, and how can it be avoided without abandoning altogether the accepted reciprocating form of steam-engine?

The station contained 10 engines of 200 i.h.p. each, and it is no exaggeration to say that a person standing on the great concrete block which formed the foundation for all the engines could scarcely tell whether those near him were running or standing. Yet complaints from houses at some little distance (rather than from closer neighbours) were evidently well founded. The engines had two cranks each, 180deg. apart, where there was an obvious couple which tended to set the engine rocking endways, and to give rise to vibration. But it was incredible that the huge block of concrete, measuring 88ft. by 24ft. by 7ft., could be tilted crossways by the couple between sets of pistons moving in lines only 2ft. 3in. apart. Besides, the effects produced and the known nature of the subsoil, led to the belief that the block was not so much rocking as lifting up and down bodily, and acting like a pump upon the water-laden soils below (the complaints were most serious after periods of heavy rain). It would have been easy to balance the "couple" if that alone were the cause, by dividing one of the lines of pistons into two, each of half the weight, and using cranks. This plan is described in Lowrie's Patent No. 3,040, of 1885, and it has also attracted attention recently. The other engine shown would have no tendency to rock endways, but it was soon seen that it would effect no improvement in the station referred to, for on closely examining the matter mathematically (in February, 1893) Captain Sankey found that in the engines in question, and, broadly speaking, in all vertical engines, the tendency to rock endways, by reason of an unbalanced couple, was much less important than the tendency of the engine, as a whole, to move vertically up and down, through a cause depending upon the obliquity of the connecting rod. Previous calculations had usually been addressed to balancing the couple as a practical solution of the whole vibration question, and though it was known that the obliquity of the connecting-rod had an effect on the result, it was believed to be disposed of by the statement that "the slight and immaterial errors due to the finite length of the connecting and eccentric rods need not be considered."*

The engines were central-valve engines of I I size, having lines of parts each weighing 420lb. They ran at about 350 revolutions per minute, and had a stroke of 9in.; the ratio of connecting-rod to crank was 4·77 to 1. The two points of maximum piston velocity are, of course, above half-stroke, hence the changes of piston velocity, and therefore the inertia forces are greater in the upper half than in the lower half of the revolution. Without going into details, it appeared that when each line of parts was near the top centre it exerted an upward pressure upon the engine of 3·54 tons, but when near the bottom centre it pressed downwards with only 2·31 tons. Twice per revolution there is a force of 1¼ tons trying to lift the engine, and twice per revolution this changes into a nearly equal force acting downwards. (The inertia curves establishing these results are given with the paper before mentioned.) A number of engines developing these unbalanced forces, and synchronising every few seconds, were probably well calculated to produce the results complained of. Needless to say, the two engines, as regards revolutions, stroke, and total weight of moving parts, would give exactly similar results in respect of the unbalanced vertical inertia forces acting upon the engine as a whole.

At the same time Captain Sankey investigated the inertia forces in a three-crank (I I I) engine, having the same revolutions, stroke, and weights of parts, but with three cranks at 120deg. instead of two at 180deg. Here the unbalanced vertical forces entirely disappeared, or rather, so nearly disappeared that they amounted to about 2lb. only, as against 1¼ tons. It was concluded that if three-crank engines were substituted for the two-crank engines, the vibration difficulties would be ended, but the engineer of the lighting company naturally hesitated to adopt a remedy based chiefly upon calculation, for, although such three-crank engines were running elsewhere, and with remarkable absence of vibration, there was nothing to show with absolute certainty that the mathematical reason was the right one. He therefore shifted the engines to another station, and put down steam-turbines instead, feeling sure that they would at least secure the object of getting rid of vibration. The result was naturally to give an impulse to the use of three-crank instead of two-crank engines for lighting stations.

In 1894 the proprietors of the Heilmann system of electric traction were in search of vibrationless engines to mount upon two very powerful electrical locomotives they intended to build, and they applied to the author's company. The engines were to be of 1,400 h.p. each, and as they were to stand fore-and-aft on the engine framing, and as no weight could be allowed in the nature of "foundation," it was decided to eliminate the "couple" as well as the vertical inertia force. This, it is hoped, will be effected by the design shown, proposed, in letters which crossed each other, both by the author and by Mons. Mazen, of the Compagnie des Chemins de Fer de l'Ouest, who is interested on the part of that company in the development of the Heilmann system. There are six cranks, virtually forming two groups, each representing a three-crank engine, with cranks 120deg. apart, and therefore, according to Captain Sankey's investigations, free from any tendency to vertical movement. If the two halves of the engine are thus free, the whole must be so. Each half of the engine, however, has a "couple," and tries to rock endways. It is designed to neutralise this effect by arranging the cranks, by inverting the two groups relatively to each other, so that they shall rock systematically towards and away from each other. Both groups being mounted on one base, and enclosed in one crank-chamber, stiff enough to prevent deformation, it is clear that the engine as a whole will be subject to no rocking effect, and as it is also free from any unbalanced vertical forces due to the finite length of the connecting-rods, it is believed that complete success will be attained. A dynamo is mounted at each end of the engine, so that each half of the crankshaft has only to transmit its own half of the power. It is evident that the two centre cranks might be replaced by one, their two lines of parts being also replaced by one of the same total

* Quoted from a patent specification.

Digitized by Google

weight; the engine would then be five-crank, but it would lose certain advantages of interchangeableness of parts, and of manufacturing facility.

Two such double engines are now under construction for a large London station, but inasmuch as longitudinal stiffness is amply provided by the concrete foundation, it is unnecessary to place the two groups of cranks in one crank-chamber. Each set consists of two I I I—S engine, each of 360 i.h.p., and each engine coupled to a dynamo. The engines are to stand end to end, the bases being bolted together, and the crankshafts connected by a detachable coupling (the governors are driven by gearing, so as not to interfere with the coupling). The coupling of the cranks does not admit of their going together in any but the right position. Either engine may be used, for light loads, as a single unit up to 360 i.h.p., in a form little likely to give rise to vibration, while at full power, when under ordinary circumstances vibration might become more serious, it is hoped that by coupling together as explained it will be entirely got rid of. The more conclusive experiment, however, will be in the Heilmann locomotives, where the engines, instead of being on solid foundations, will be, of course, suspended on springs.

Perhaps the very simplest form of completely-balanced engine is one which was used in the earliest Heilmann locomotive. Two examples are shown—a compound and a triple-expansion. Of course, in both cases the total weight of the moving parts must be the same on the two sides of the crankshaft, and the cranks must be 180deg. apart, and the connecting-rods and cranks of equal length. Both engines provide for the varying inertia forces due to the finite connecting-rods. The forces vary at the same times and in opposite directions, and so neutralise each other completely, instead of only partially. This form of engine needs to be horizontal. If used as a vertical engine, one crank must be driven from below, which is practically impossible in a marine engine, and cannot be generally convenient in other situations. Since the cranks must be opposite, such an engine also cannot have the even turning moment of an ordinary three-throw engine, and for marine purposes it would require to be duplicated—*i.e.*, to have six cranks—for the sake of avoiding dead centres.

Numerous proposals have been made to balance engines by "bob-weights"—dummy pistons driven by eccentrics. The couples in an engine can be thus balanced: not the other forces, unless the bob-weights are placed below, and are as heavy as the pistons. The subject is, however, far too complicated to receive more than superficial notice here.

In addition to the foregoing matters, it might be of interest to say something about the governing of central-station engines. This subject, however, needs a paper, to say the least, to itself; moreover, experience with single-acting engines can teach no lesson substantially different from what may be learned from double-acting engines, unless it be that the former, by reason of high speed and many impulses per minute, and the small amount of steam contained within the engine at any one time, are somewhat easier to govern. As regards steady running, in the sense of smallness of variation in speed during each revolution the high-speed engine has, of course, enormous advantage. The engines before referred to as driving a flax mill in Belfast gives an almost perfectly straight line upon the recorder, although the instrument used could be set to feed the paper so quickly that the change of speed in each separate revolution was apparent; its effect was limited, however, to the width of a narrow line. In this engine, with three cranks, there were 900 impulses per minute, all exactly equal, and it was not wonderful that with a pulley flywheel weighing only six tons, and of 5ft. diameter, better results were attained than in slow-running engines with flywheels many times as heavy. The same remarkably steady drive has been observed in another engine of the same type (but with two cranks only) driving a cotton mill. This, of course, is not governing, but merely testimony to flywheel efficiency. It is a subject, nevertheless, of great importance, and one which perhaps was somewhat neglected in the earlier days of the high-speed engine, when flywheel power was certainly cut fine.

As the flywheels have been made more powerful, so have the governors. If central-station experience tells anything, it is that if you want prompt and sensitive governing and freedom from hunting, you must first provide a very powerful governor, and then give it next to nothing to do. The Willans governors are now, owing to the high speed of rotation, and the much heavier balls in use, enormously powerful in proportion to the work to be done, which consists only in moving the (piston) throttle-valve, and, in automatic expansion engines, the very small steam-valve which controls the relay cylinder. The consequence is that a very restricted movement of the balls makes the desired change in minimum time, while leaving plenty of margin to deal with unaccustomed resistance, due to such causes as dirt or neglect. It is hardly possible that the most powerful shaft governor can have as much power relatively to the calls upon it in shifting eccentrics, links, etc., as is possessed by the governor of any recent Willans engine.

There is no subject about which more confusion exists in engine-rooms than the relative parts played by the governor and by the flywheel. They are certainly closely allied, but very often when the governor is blamed, it is really the flywheel which is in fault—that is to say, with reference to the particular work the engine is called upon to do. On the other hand, many a governor owes its reputation to the flywheel, whose huge weight forbids the engine to take serious notice of a change of load, until the governor, possibly in itself neither a powerful one nor a good one, has had time to adapt itself to changed conditions. Of course, a heavy flywheel cannot affect the permanent change of speed due to a change of load, but it depends largely upon the flywheel whether the momentary variation shall be great or not.

The great question of throttling *versus* variable expansion has been fully dealt with by Captain Sankey in a paper read at the spring meeting this year of the Institution of Mechanical Engineers. It must suffice to say here that variable expansion is desirable for practical convenience, rather than for economy, in a great many cases, and for economy in some, but that in no ordinary case does the economy rise beyond a very moderate percentage, and that only through a small part of the range of variation of load. It is also established, upon the basis of Mr. Willans's experiments, that at very high loads (say quarter load, or even more) it is distinctly more economical to throttle the steam than to continue to make the cut-off earlier, and maintain the full pressure in the steam-chest—since in the latter case, for only a small useful load, the full initial condensation is maintained, and the full loss by radiation. When the initial temperature in the first cylinder is reduced (as it is by throttling) both these sources of loss are diminished. Perhaps the most useful effect of automatic gear is that, by its aid, an engine can be occasionally overloaded without having to carry the same late cut-off at all times. Where the normal load is also the maximum load (as it should be in lighting stations, where the plant works in parallel) the engine is, of course, designed to give that load economically—*i.e.*, with cylinders of such size as to give the full load at a moderate mean pressure. In this case when light loads are carried—if they ever are carried: it would be better to avoid them—it is not of much importance whether the power is reduced by throttling or by altering the expansion. Now, take such a case as that of electrical traction, where the average load is small, perhaps only half or two-thirds the maximum; it is evident that the cylinders, and the normal expansion, should be designed to suit the average load—but this cannot be done without the use of automatic expansion, because provision has to be made for the occasional overload. By automatic expansion it is possible to keep the cylinders of such an engine small, and suitable for the normal load, and yet readily take more power from it for short periods. The periods of overload are, of course, wasteful, but this is far less important than wastefulness during the much longer periods of average load.

The mode of varying the cut-off in the Willans engine is by a sleeve working upon the trunk or hollow piston-rod, where it passes into the steam-chest at the top (see description in appendix). There are inclined ports in the trunk and in the sleeve, and by rotating the latter by means of gear outside (or sometimes inside) the steam-chest, the cut-off is made early or late. The system adopted is one originally planned by the author, but which owes its practical form to improvements carried out by Captain Sankey. A throttle-valve is used, and on, say, a drop in load, reduces the pressure in the steam-chest in the usual way. The rotating sleeves are controlled by a small steam-cylinder, the piston of which is exposed to boiler pressure on one side and to steam-chest pressure on the other. On the drop referred to taking place, the piston moves towards the steam-chest, and the cut-off is altered, in the sense of being made earlier; means are provided to prevent too rapid movement of the cut-off gear in this direction; slowness or jerkiness of action is immaterial, because the throttle-valve has always control over the speed. As the cut-off changes, the pressure in the steam-chest gradually returns to what it was before, or nearly so. The return journey of the relay piston offers more difficulty, and if effected only with the apparatus as yet described, it would require a considerable permanent difference of pressure between the steam-chest and the boiler. Captain Sankey has made this unnecessary by providing that when the engine speed falls, the spindle which moves the throttle-valve shall also move a small valve which both cuts off the boiler steam from the relay cylinder, and allows the steam already in this cylinder to exhaust into the receiver or some other place of lower pressure; as the relay piston moves it makes the cut-off later. The point of cut-off is at all times indicated externally by an index and pointer, the latter forming also a handle to enable the gear to be worked by hand if preferred. The gear has the great advantage that by merely fixing a stop, the range of variation of cut-off can be limited, so that, on the one hand, the engine may not be grossly overloaded, and, on the other, the expansion may not be carried too far for economy. In fact, the engine governs by varying the expansion down to a certain mean pressure (dependent, of course, upon boiler pressure and other circumstances) and below that by throttling, which is exactly the ideal arrangement for economy.

Digitized by Google

In conclusion, the author thinks it may fairly be claimed that the single-acting high-speed engine has justified the favour shown to it by electrical engineers, in regard both to that which it has already accomplished and to the prospect which it holds out of further successful development. Its success, as in all similar cases, has but fostered improvement in other engines, and it may be doubted whether central-station engines in this country, either of the slow-speed class or of the high-speed double-acting class, or even the deeply interesting steam-turbine, would have attained to their present perfection had they lacked the spur applied by the progress of the Willans engine, and of others like it. For good or ill, the wide adoption of the single-acting high-speed engine marks a bold step in engineering. It is essentially of English origin and development, and its success bears witness that English engineers, though cautious, are also bold when boldness is called for. That it has fallen to members of this Institution to be leaders in so striking an innovation may perhaps earn a friendly tolerance for the many shortcomings of this attempt to place on record the more salient features of the system.

PHYSICAL SOCIETY.

At the ordinary meeting on May 10, 1895, Captain Abney, president, in the chair,

Mr. Herroun read a paper on the "**Iodine Voltameter.**" After referring to the usual methods of determining the value of the small currents used in calibrating galvanometers and other apparatus for measuring small currents, and discussing the errors to which they are subject, the author gave his reasons for selecting iodine. He did this since, with the exception of mercury in the mercurous state, iodine has the largest electro-chemical equivalent, and, in addition, by titration with sodium thiosulphate, it is possible to determine the quantity of iodine liberated with a greater accuracy than can be obtained by weighing a deposit of copper or silver with the balance. The solution employed in the voltameter contains 10 to 15 per cent. of zinc iodide. If care is taken to leave a small piece of metallic zinc in this solution, no free iodine is liberated on keeping, unless the solution is exposed to a strong light for some time. The anode consists of a plate of platinum at the bottom of a tall and fairly narrow beaker. The wire leading the current to the anode is encased in a glass tube, so that the iodine is only liberated at the bottom of the beaker, where on account of its great density it tends to collect. The cathode consists of an amalgamated zinc rod, which, to prevent loose particles of zinc falling down into the iodine, is surrounded by a piece of filter paper or vegetable parchment. In an electrolysis lasting for as long as two hours none of the iodine is found to diffuse up to the part of the solution near the zinc cathode. Where, on account of the extreme feebleness of the current employed, it is necessary to allow the electrolysis to continue for longer than two hours, a U tube is used with two small plugs of asbestos at the bend, the anode being in one limb and the cathode in the other. With this form of voltameter, even after the current has flowed for several days, no signs of iodine have been found in the limb containing the cathode. On account of the production of electric convection currents, the iodine voltameter does not seem to be quite so suitable for accurate measurements of strong currents. After the current is stopped the zinc electrode is immediately removed, the solution stirred, and the amount of iodine liberated determined by titration with sodium thiosulphate. The author finds that a convenient strength of the thiosulphate solution is one in which 1 c.c. corresponds to the amount of iodine liberated by five coulombs of electricity. This solution contains 12·8375 grammes of pure recrystallised sodium thiosulphate per litre. It is possible to perform the titration to within 0·1 c.c., which corresponds to 0·5 coulomb, or if the electrolysis last one hour to $\frac{1}{720}$ ampere. In a comparison made with a silver voltameter, the current as deduced from the silver was 0·0264 ampere, and that deduced from the iodine 0·0266. The author considers that part of the difference may be due to the effect of oxygen dissolved in the solution of silver nitrate.

Prof. Carey Foster considered this process for measuring currents a most valuable one. The idea of using a volumetric method for measuring currents was to him new. He did not, however, see the advantage of using a substance with a high electro-chemical equivalent, if a volumetric method was going to be employed to estimate the quantity of the substance liberated. It would be possible to use a chloride, though in this case the titration would probably be less accurate.

Prof. Silvanus Thompson said he thought the method would be very valuable, but he would like to know if any error was likely to arise if too great a current density was employed. The number the author had assumed for the atomic weight of silver (108) was only approximate. If the more accurate value 107·7 were used, the agreement between the results obtained with the silver and iodine voltameters would be improved.

Mr. Trotter asked what was the largest current that could be accurately measured.

Mr. Enright said he had used porous diaphragms in iodine voltameters, and found that the iodine collected in the positive compartment, while the water was driven over into the negative compartment. With strong currents it was possible to get almost pure iodine left in the one compartment.

Mr. Watson thought that since the value for the electro-chemical equivalent of iodine used by the author was deduced from Rayleigh's value of the electro-chemical equivalent of silver, and that Rayleigh's experiments were performed in air, the difference obtained with the silver and iodine voltameters could hardly be due to the cause suggested.

Mr. Elder warned the members that volumetric measurements were not so accurate or easy as they seemed. He particularly mistrusted a solution of sodium thiosulphate, since he had found a solution of this substance to change even in 24 hours. The difficulty of accurately reading the burette might be overcome by weighing the burette and its contents before and after the titration.

The Author, in his reply, said that with the size of electrodes he used (about nine square centimetres surface) 0·1 ampere was the maximum current it was safe to use. The only substance likely to be produced by too great a current density was periodate, which, since it was insoluble, would immediately be noticed. The influence of the dissolved oxygen was only appreciable with small currents where the electrolysis lasts some time, while in Rayleigh's experiments large currents were employed.

The Chairman, while returning thanks to the author for his paper, mentioned that in his experience he had found zinc salts to be very untrustworthy.

THE SELECT COMMITTEE ON TELEPHONY.

The Select Committee of the House of Commons on the Telephone Service heard further evidence on Tuesday, Mr. A. Morley presiding.

The **Hon. J. G. Ward**, Postmaster-General of New Zealand, and member of the Legislative Assembly, was the first witness, and, in answer to the **Chairman**, stated that in the colony both the telegraphs and the telephones were in the hands of the State. The colony legislated in the first instance to prevent anyone else introducing the telegraphic or telephonic system. At the start they had in the colony 116 subscribers, and now they had nearly 5,000. The total cost up to the end of the last financial year was £104,500, and the total earnings £183,000. Against the total earnings they charged 10 per cent. for depreciation and interest on capital, cost of staff, rent of premises, and other expenses, leaving the net earnings £54,082. Even with their small system they were opposed to centralisation. Their experience was that subdivision of exchanges led to speed. The charge to subscribers was £5 per annum for business purposes within half a mile of the exchange and a mile for private houses, with a graduated increased charge for longer distances.

Mr. Dickinson, deputy chairman of the London County Council, stated, by way of supplementing his former evidence as to the unsatisfactory service of the National Telephone Company, that on May 6 of the present year a circular was issued under the authority of the County Council to the users of the telephone service in London, 7,359 in number. Each subscriber was asked whether, in his opinion, the existing service was efficient and satisfactory; if not, in what respects was it unsatisfactory; and finally inviting suggestions as to improvements. In reply, 2,536 replies were received, of which 555 subscribers expressed entire satisfaction and 1,981 were not thoroughly satisfied. Of the 1,981, 1,305 expressed general dissatisfaction, 350 were undecided as to making suggestions for improvements, and 326 expressed themselves satisfied, but suggested improvements.

Mr. Forbes, president of the National Telephone Company, was next examined. He said that in the matter of the circular issued to the users of the telephone the company rather scored over the County Council as in response 2,346 subscribers signed unconditionally, 266 signed with qualifications, 43 were in favour of the County Council, and 36 refused to sign. He narrated the history of the telephone company, and cited a variety of statistics showing its growth and development. The number of subscribers as at December, 1894, was 73,383, as compared with 27,706 in 1892. The number of towns and places supplied was 537, exchanges open 593, number of subscribers' lines 75,116, and number of telephones in use 86,032. The present ratio of effective calls per annum was 139,639,000, and as each conversation involved two persons, the caller and the called, the number of messages was 279,278,000. He then dealt with the complaint that the service was charged for at an extortionate rate, and stated that the average annual payment per line was £9. 2s. 2d. The term "subscriber" conveyed no meaning. The Midland Railway Company was a subscriber, although it had a great many lines. The company, he added, recognised that they were agents of the Post Office. He felt when he visited the Post Office that he was as much an official as anyone else. The Post Office had charged them with a public duty, and they recognised that it was their duty to adapt themselves to the public convenience. At the end of this year London would be entirely served on the metallic system. That was a serious undertaking, having regard to the disturbance which inevitably must take place to the service while the change was being effected. He had no doubt the greater part of the complaints during the last three or four years in London was due to the change of system.

The committee adjourned till to-day (Friday).—*The Times.*

Electric Light Legislation in Ceylon.—With the advent of the electric light in Ceylon it has been thought necessary to introduce an ordinance to provide for the protection of person and property from risks incidental to the supply of current.

COMPANIES' MEETINGS.

WEST INDIA AND PANAMA TELEGRAPH COMPANY, LIMITED.

The thirty-sixth ordinary general meeting of this Company was held at Winchester House on Wednesday, Mr. C. W. Earle occupying the chair.

The **Chairman** said that the report was the least satisfactory in its results of any they had had to submit since 1882. He did not know to which side of the table more sympathy was due—whether to the shareholders for their long-continued self-denial in restoring the Company to its present position of credit, or to the directors, who were disheartened at finding the poor dividend they had been in the habit of giving diminished, and all the labour which had been devoted to supplying a substantial service rendered almost fruitless to the ordinary shareholders. The only consolation the directors had was that the causes of this unfortunate condition of things were entirely beyond their control. At the last meeting he alluded to one or two of these cause, and notably the decline in the business of the West Indies, the fall in the value of sugar, and the increased skill with which merchants used the codes. In 1869, when the Company was first started, the Colonial Governments laid down a tariff with a minimum of 20 words, and it was only in deference to the growing custom among telegraph companies that the word "rate" was introduced some 12 or 15 years ago. By the introduction of that the average message, instead of being 20 words, was now about 7·25 words. The expenditure was £1,011 more than in the corresponding half-year, of which £952 was due to circumstances over which they had no control, the winds and waves of the West Indian seas not having been tempered this half-year to the Company. They had received £1,022 less than in the corresponding period, and, with the £1,011 more expenditure, they had done less well by £2,033. Had they received that amount, they would have been able to pay the 6d. dividend. As to the prospects of the current half-year, the traffics were slightly diminished. The expenditure on cables he hoped would not be great, but at the same time, as announced in the report, the Company would lose £2,000 per annum hitherto paid by the Island of Guadeloupe. The prospects of the Company, therefore, were not on the whole very bright. It was rather curious that, while this diminution of revenue and the difficulties they were going through were apparent to everybody, meetings were being held in the principal colonies of the West Indies and resolutions passed calling upon the governors to put pressure on the Secretary of the Colonies to subsidise, at the cost of the English taxpayer, a single line of cable. This cable they were asking was to run into the middle of this Company's system, and reduce the receipts to about 3s. a word. He did not know whether there was any chance of such a measure being adopted, but it should be remembered that this Company's system was duplicated by the desire of the West Indian colonies, so as to supply a reliable service without interruptions, and it seemed rather hard that they should be agitating for a single cable. He did not much fear that the movement would have any effect, but at the same time they must always be prepared for some surprise of the sort One of the arguments put forward was the advantage of having cables passing through British possessions, but in the event of war with a continental Power there would be no more safety for tactical cables than for those belonging to commercial companies.

The report was adopted.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Manchester.—Tenders are invited by the Corporation for painting offices, etc., at the electric light station. Particulars and forms of Mr. Nickson, Town Hall, Manchester. Tenders by 12 noon on 27th inst.

Godalming.—The Town Council invite proposals for the installation of the electric light for public and private lighting within the borough. Further particulars may be obtained upon application to Mr. Samuel Welman, borough surveyor, Church-street, Godalming.

Oldham.—The Corporation Electric Light Committee require tenders for supplying two 200-h.p. steam-engines and dynamos, steam-pipes, etc. Specifications and forms of tender may be obtained on application to Mr. Arthur Andrew, Gas and Water Offices, Oldham, to whom tenders are to be sent, endorsed "Tender for Engines and Dynamos," on or before the 28th inst.

London, E.—The Shoreditch Vestry invite tenders for the wiring of the Shoreditch Town Hall, including supplying and fixing cables, wires, switches, switchboards, etc., for the electric lighting of the building. Specifications and particulars may be had of the lighting engineer, Mr. C. H. Doughty, at the Town Hall, Old-street, E.C. Sealed tenders, endorsed "Tender for Wiring, etc.," must be sent to Mr. H. Mansfield Robinson, solicitor and vestry clerk, at the Town Hall, by 10 a.m. on 31st inst.

Huddersfield.—The Electric Lighting Committee of the Huddersfield Town Council invite tenders for high and low tension cables, and transformers, complete in cast-iron cases, with switches, fuses, and covers, required during the ensuing twelve months. Specifications and form of tender may be obtained on application to Mr. A. B. Mountain, borough electrical engineer, St. Andrew's-road, Huddersfield, to whom tenders are to be sent not later than the 1st June, endorsed "Tenders for Cables and Transformers."

Hanley.—The Corporation invite tenders for the supply, delivery, and erection complete of two Lancashire boilers and fittings, including steam receiver; water-tank and girders; arc lamps and posts; high and low pressure cables, street boxes, cast-iron pipes, etc., in certain streets in the borough; transformers, switches, etc. Forms of tender may be obtained, and specifications and plans inspected, at the office of Mr. Joseph Lobley, borough engineer and surveyor, Town Hall, Hanley. Tenders must be sent in to the borough engineer before the 27th inst.

London.—The Secretary of State for War gives notice that purchases of specific quantities of various articles will be made from time to time during the current year. Among them are electrical instruments for submarine mining and telegraph cable and wire. Manufacturers who may be desirous of tendering should apply to Mr. G. Lawson, director of army contracts, War Office, Pall-mall, S.W., by letter, giving at least names of two well-known firms or public bodies who have purchased from them and are in a position to certify as to the quality of their productions. Applications unaccompanied by references will not be noticed. Firms whose names are already on the War Office list need not apply, as forms for tendering will be sent to them in due course.

Brighton.—Tenders are invited by the Corporation for (*a*) the preparation, supply and delivery at Brighton of cast-iron lamp pillars and copper canopies for electric light arc lamps; (*b*) the preparation, supply, and delivery at Brighton of cast-iron and drawn-steel bracket posts for suspending electric light arc lamps. Drawings may be seen, and specifications and forms of tender obtained, at the office of the borough engineer and surveyor at the Town Hall, Brighton, on payment of £1. 1s. for each specification. Sealed tenders, addressed to Mr. Francis J. Tillstone, town clerk, Town Hall, Brighton, and endorsed "Tender for Cast-Iron Lamp Pillars" or "Tender for Iron and Steel Bracket Posts," must be sent to the town clerk's office at the Town Hall before June 1 for the former and May 27 for the latter.

Manchester.—Tenders are invited by the Paving, Sewering, and Highways Committee for the execution of the following works: Contract No. 1—viz., laying a system of underground telephone pipes, with brick inspection pits, service boxes, and other appurtenant works in the following streets: (Route 4) Portland-street, Princess-street, Hart street, Sackville-street; (4a) Altrincham street, Lower Albion-street; (4b) Charles-street, Carpenter-street; (4c) Hart-street, Chatham-street, London-road, Booth-street, Dale-street, Stanley-street; (4d) Dale-street, Spear-street, Bennet street; (5) Portland-street, Chepstow-street, Great Bridgwater-street, Albion-street, Little Peter-street, Greaves-street; (5a) Oxford-street, Hulme-street. Drawings may be seen, and copies of specification, bills of quantities, and form of tender may be obtained, on application at the city surveyor's office, Town Hall, Manchester, on payment of £5. 5s., which sum will be refunded on the return of the documents and the receipt of a bona fide tender. Sealed tenders, enclosed in the official envelope, to be sent in by 31st inst.

RESULTS OF TENDERS.

Coventry.—The tender of Mr. C. Haywood, jun., has been accepted for the erection of a generating station for electricity, car-shed, boilers, and dynamos, for the Coventry and district tramways.

Brighton.—The following tenders have been received by the Corporation for the supply and erection of boilers at the Corporation electricity works, and for the supply of cables:

Supply and erection of boilers.

H. and T. Danks, Limited, Dudley	£4,750
Yates and Thom, Blackburn	3,785
Hawkesly, Wild, and Co., Sheffield	3,750
J. Thompson, Ettingshall, Wolverhampton	3,660
Davey, Paxman, and Co., Colchester	3,644
Penman and Co., Glasgow	3,500
Fraser and Fraser, Limited, Bromley-by-Bow	3,486
R. Hornsby and Sons, Limited, Grantham	3,300
Babcock and Wilcox, London (accepted)	3,100
Tinkers, Limited, Hyde, near Manchester	3,060
J. Fraser and Son, Millwall	2,938
Spur, Inman, and Co., Limited, Wakefield	2,870
Fleming and Ferguson, Paisley	2,760
E. Danks, Oldbury	2,627
R. Taylor and Sons, Marsden, Yorkshire	2,165

Supply of vulcanised rubber and lead-covered and armoured cables at per mile.

	A.	B.
India Rubber, etc., Company, Silvertown	£396	£297
W. T. Henley's Telegraph Company, London	337	279
Telegraph Manufacturing Company, Helsby	335	281
Fowler-Waring Cables Company, North Woolwich	328	268
W. T. Glover and Co., Salford	298	240
Callender's Bitumen, etc., Company, London	290	255
Siemens Bros. and Co., London (recommended for acceptance)	289	239
British Insulated Wire Company, Prescot (accepted, but since withdrawn)	230	215

A, Three-core cable. B. Two-core cable.

BUSINESS NOTES.

Worthing.—Mr. Mellor's Committee have confirmed the Worthing provisional order.

Falmouth.—The lighting of the town by electricity has been mooted at the Town Council.

Western and Brazilian Telegraph Company.—For the past week the receipts were £2,584.

Hove.—The surveyor to the Urban Council is preparing a report on the subject of the electric light.

Ashby-de-la-Zouch.—The Urban District Council have under consideration the question of lighting the town electrically.

Motherwell.—The Committee of the House of Commons on Unopposed Bills has passed the Motherwell Electric Lighting Bill.

Newport (Mon.).—A new museum has been built as an adjunct to the free library premises in Dock-street. It will be lighted by electricity.

Dundee.—Messrs. Lowden Bros. have obtained the contract for lighting the Samnuggur, Titaghur, and Victoria jute mills in India by electricity.

Epping Forest Railway.—The London, Walthamstow, and Epping Forest Railway Bill was read in the House of Commons on Monday for the second time.

Bangor (Wales).—Mr. Medhurst, who has been appointed consulting engineer to the City Council, is now preparing a report upon the electric lighting of the town.

Change of Partnership.—Mr. S. V. Clirehugh, A.M.I C E., A.I.E.E, of Temple-chambers, Brazennose-street, Manchester, has dissolved partnership with Mr. R. Wilson.

Walthamstow.—Mr. Mellor's Committee on Tuesday confirmed the provisional order made by the Board of Trade under the Electric Lighting Acts relating to Walthamstow.

Mica.—We are informed that Mr. Archibald Campbell, of 28, Gray's-inn-road, W.C., has secured a contract with the Admiralty for mica on behalf of Baxters and Macdonald, Dundee.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 19th inst. amounted to £1,141, as compared with £1,282 in the corresponding week of last year.

Brighton and Rottingdean Seashore Electric Tramroad Company.—The prospectus of this Company has been issued, the capital being £20,000. The share-list closed on Wednesday.

Winchester.—The provisional order made by the Board of Trade under the Electric Lighting Acts with respect to Winchester has been confirmed by Mr. Mellor's Committee in the House of Commons.

Richmond-on-Thames.—The Fire Brigade Committee of the Town Council have reported that the Local Government Board have sanctioned the loan for the Kew and Petersham fire-call extension works.

Walsall.—A meeting of the Town Council has been held, at which, in reply to Councillor Baker, the Town Clerk said that the Electric Lighting Committee hoped to be ready to supply current to the public by the end of August.

Weston-super-Mare.—The Urban District Council have instructed their clerk to take initial proceedings at once for a renewal or extension of the electric lighting provisional order which has been obtained for the lighting of the town by electricity.

Chiswick.—A committee of the Urban District Council have reported that instructions had been given to Messrs. Bourne and Grant to stop the erection of the shaft at the central electric light station pending a satisfactory agreement being entered into with the Council.

Ossett.—A meeting of the Town Council has been held, at which a letter was read from Mr. B. Greenwood, solicitor, Ossett, respecting the formation of a company for electric lighting, and the town clerk was instructed to reply stating that the matter was under consideration.

Railway Station Lighting.—It has been decided to light electrically the Tunbridge Wells Stations, on the South-Eastern Railway. The contract has been placed in the hands of Messrs. Drake and Gorham, of London, Manchester, Scarborough, and Tunbridge Wells.

Southport.—The Town Council have decided, on the advice of experts, to lay a single concentric cable of the same size as the present high-tension cables, rather than two cables in pipes as previously proposed. The object is to light the new infirmary and to supply current to houses on the route.

Wigan.—The Town Council have decided that the town clerk inform the Board of Trade that they have no observations to offer on the draft regulations and conditions which the Board have prepared for securing the safety of the public, and for ensuring a proper and sufficient supply of electrical energy.

Poplar.—A meeting of the District Board of Works has been held, at which a letter from the Board of Trade, transmitting a set of new rules and regulations for securing the safety of the public in regard to electric lighting, and asking for the observations of the Board thereon, was ordered to be left in the hands of the clerk.

Taunton.—The Town Council have decided that the electric lighting posts between the centre of the town and the railway station be taken down. They have also decided that the sum of £500 be paid to the Fowler-Waring Cables Company, Limited, on account of the cables supplied in connection with the arc lighting and the No. 2 sub-station.

City and South London Railway.—The returns for the week ending May 19 were £905, compared with £907 for the corresponding period of 1894, being a decrease of £2. The total receipts for the current period of the present half-year are £18,720 against £18,213 in the corresponding period of 1894, an increase of £507.

Aberdeen.—The Aberdeen County Council have received a letter from the manager of the Northern Electric Supply Company at Cults requesting the consent of the Council to an application to be made to the Board of Trade for a provisional order authorising the supply of electricity. This was, on the motion of the convener, sent to the District Committee.

Killarney.—The Town Commissioners have written to the Board of Trade informing them that the accounts for the years 1892-93 and 1894 of the Killarney Electric Lighting Company have not been lodged with the Board of Commissioners as required by the Board of Trade regulations, and enquiring what steps will be taken to have their regulations fully complied with by the company.

Windermere.—The District Council have held a meeting, at which the clerk reported that he had received a copy of the provisional order which had been granted to the Windermere and District Electricity Supply Company, Limited, of Troutbeck Bridge, by the Board of Trade, but it contained nothing of importance beyond what had previously been before the notice of the Council.

D. P. Battery Company, Limited.—This Company has been registered, with a capital of £10,000, to adopt an agreement expressed to be made between W. C. Johnson of the first part, B. Drake and J. M. Gorham of the second part, and this company of the third part, and to carry on business as manufacturers of and dealers in storage batteries and other electrical appliances, and as electrical engineers generally.

Colwyn Bay.—A meeting of the District Council has been held, at which Mr. Davies moved that the Council give instructions to their clerk to apply for a provisional order for supplying their district with the electric light, and that a committee be appointed to take any necessary steps to obtain further powers to spend money in advertising the town, etc. It was desirable to bring the gas company to their senses. Mr. Blud seconded the motion, and it was carried.

Cooling Apparatus.—A successful installation of cooling apparatus by means of compressed air has been satisfactorily completed by Messrs. Baird, Thompson, and Co., Limited, for Lord Wenlock, of Escrick, Yorks. (the present Governor of Madras). By this apparatus the whole of the estate dairy produce, butter and cheese factories, provision and poultry stores, etc, can be kept at a low temperature, even in the warmest weather, without freezing.

Drumcondra.—Mr. G. Collins, solicitor (Messrs. Casey and Clay), and Mr. W. Anderson, J.P., secretary to the Dublin United Tramways Company, have waited on the Town Commissioners and explained the object and scope of the Bill which the company are promoting in Parliament for enabling them to use electric power for tram traction. On the motion of Mr. McMahon, seconded by Dr. Eustace, a resolution was passed approving of the Bill, and adopting a petition in favour of it.

Surbiton.—The clerk to the Council has read a circular letter from the Board of Trade, enclosing a draft of the revised electric lighting regulations, and asking for the observations of the Council thereon. The Chairman said it was a technical matter which had come just at the right time, and he thought it would be just as well to refer it to the Electric Lighting Committee. This was agreed to, and the following gentlemen will constitute the committee: Messrs. Judd, Marshall, Lapage (the vice chairman), and Maddick.

Bury St. Edmunds.—The Town Council have received a letter from Messrs. C. Oliver and J. Vale Richardson stating that they were putting down plant for electric lighting to their premises in Abbeygate-street, and had been asked to supply tradesmen on the opposite side of the street. They asked permission to lay a pipe across the road for that purpose. Permission was granted subject to the Electric Lighting Act, Messrs. Oliver and Richardson to pay a nominal rent of 1s. per year, and entering into an agreement to remove the pipe if required, the work to be done to the satisfaction of the borough surveyor.

Kingston-on-Thames.—The town clerk (Mr. H. A. Winser) has written to the Board of Guardians that the Lighting Committee of the Corporation requested him to suggest to them the desirability of introducing electric light into the workhouse, and that if the Guardians contemplated doing so the borough electrical engineer would be pleased to give whatever information was wanted on the subject. The Chairman said the Guardians had already agreed that there should be electric light in the new infirmary. Perhaps it would be as well to wait until that installation was completed before they considered any extension of it. This was agreed to.

Bristol.—A meeting of the Sanitary Committee has been held, at which the acting clerk read some communications which had taken place between the surveyor and the tramways company with reference to the removal of the urinals, cab stand, and rest in Old Market street, if the tramways company would place their new lines for the electric traction trams nearer together than the present ones, in order that more room might be provided for the ordinary traffic. The tramways company wrote favouring the proposal, but it was agreed to defer the matter, in order to consult with the surveyor upon the question.

Aberystwith.—A meeting of the Town Council has been held, at which Councillor Thomas called attention to the subject of the

Digitized by Google

electric light. He said the Council had contracted for the light to be on from sunset to midnight. He considered that this was an unnecessary waste of money, besides the light was not put on until an hour after sunset. He hoped, therefore, the company's attention would be drawn to the matter, and that they would not charge them for the time when the lamps were not lit. Alderman C. M. Williams proposed that the matter should be left to the Public Lights Committee. Councillor D. C. Roberts said that the committee had the matter in hand.

Liverpool.—A meeting of the Special Lighting Committee of the Corporation was held on Monday, Mr. Alderman Fred. Smith presiding, when the draft agreement between the Corporation and the Liverpool Electric Lighting Supply Company with regard to the purchase of the company's rights and plant in Liverpool by the municipal body at a cost of £400 000 was under consideration. It is understood that the agreement has been approved by both parties, and that the Corporation will become the owners of the undertaking in due course. Parliamentary powers must, however, be acquired by the Corporation to enable it to take over the concern, and it is expected that these powers will be secured during the present session of Parliament.

New London Mains.—Applications were approved of by the London County Council on Tuesday from the Vestry of St Pancras for the construction of a sub-station in Wells-street, Gray's-inn-road, upon condition that adequate means be taken to secure the efficient ventilation and drainage of the sub-station; from the House-to-House Electric Light Supply Company, for laying mains in and across Earl's Court-road, in Earl's Court square and road, and across Penywern-road; from the St. James's and Pall Mall Electric Light Company, for laying mains in Beak-street; from the City of London Electric Lighting Company, for laying mains in Martagon-place and across Sumner-street; and from the Westminster Electric Supply Corporation, for laying mains in Pollen-street.

Copper.—The copper statistics for the first half of May show that the consumption was 510 tons less than the deliveries in this period, and the visible supply is therefore so much larger—54,749 tons, against 54,239 tons at the end of April. With regard to the recent fall in Rio Tinto, there is no ground for it beyond the realisations of an eminent firm, who are known to have bought a large option for the call to the end of June. That the new agreement has not yet been signed is also true; but the reason is simply that, several of the largest producers in America being away, the others have stated that there is no pressing hurry to enter into a convention, since under no circumstances can the amount of copper available for export to Europe in the next 12 months exceed 60,000 or 65,000 tons—which is all that the agree ment stipulates for.

Stafford.—The Electric Lighting Committee of the Town Council have reported that the contractor has nearly finished the work at the supply station, and that the cables were in course of being laid down. On the consideration of the report of this committee, a discussion took place respecting fitting up private premises with the electric wires by workmen employed by the committee. Letters had been received from private firms complaining of the competition. Mr. W. H. Peach defended the action of the committee, saying that they had engaged competent men, and the committee contended that it was in the interests of the Corporation, as well as in the interests of the general body of the ratepayers, that the department's workmen should put in the fittings No amendment was moved, and the action of the committee was approved.

Huddersfield.—The Town Council have confirmed the minutes of the Electric Lighting Committee's meetings, which set forth that the borough accountant reported that the balance of unexhausted borrowing power for the purpose of capital works of this department amounted to £3,312. 17s.—£870 11s. 6d. in respect of buildings, repayable within 30 years, and £2,442. 5s. 6d. for general purposes repayable within 15 years—and the electrical engineer reported that the further amounts likely to be required would be £15,000 for purposes of buildings and £35,000 for general purposes. The town clerk was instructed to take steps to obtain powers for borrowing the sum of £50,000. The Plant Sub-Committee, after considering a report from the engineer upon the inspection of generating machinery at the electric supply station, recommended the adoption of Messrs. S. Z. de Ferranti's plant at £3,558.

Cardiff.—The Cardiff borough engineer, Mr. Harpur, states that satisfactory progress is being made with electric lighting in the town. There are now 60 consumers, using between 4,000 and 5,000 lamps About a quarter-past ten on Monday night every alternate lamp in the streets went out. A meeting of the Cardiff Lighting and Electrical Committee was held on Tuesday, when the clerk read a letter from the Local Government Board in reference to an application to borrow £3,500 for public lighting. The money is required to purchase the old brewery in Womanby-street for the purposes of an electric lighting station. The Board stated that they were prepared to sanction the loan as soon as they were informed that Jones's-court had been acquired and the question of ancient lights overcome. The chairman stated that the Corporation had arranged to purchase Jones's-court, so that was all right.

Dover.—A memorial has been received by the Town Council from the inhabitants of Snargate-street calling attention to the lighting of the street and suggesting that electric lights should be substituted. The memorial was signed by the whole of the occupiers of the street (191). Councillor Mackenzie said he believed that the electric mains were laid down the street, and he should move that the electric light company be asked on what terms they would light the street by either brackets or from light arches thrown across the street, which would doubtless be a most striking way of lighting a narrow street. The Mayor suggested they might approach the company as proposed; the idea of light arches was a splendid way of lighting Snargate-street. The motion was carried. The Board of Trade electric regulations were referred to Mr. Slingo for report, the town clerk stating that an important alteration had been made in them.

Newcastle.—Parliamentary powers having been obtained to work two large sections of the Newcastle tramway lines, the property of the Corporation, by cable, a proposal has come before the committee from a firm of electrical engineers to form a syndicate to work the proposed City-road line by the overhead wire system, the same as at Leeds to the Roundhay Park. They would guarantee 6 per cent. on the cost of construction, and limit the fare to one penny per mile. The proposal was adjourned to see if the promoters could induce the local authority of Walker, a populous place adjoining the city boundary, to agree to the extension of the line, and also to get over the difficulty of going through the part of the city to the central station, where overhead wires would be strongly opposed. The borough engineer submitted a report in regard to the Chicago tramways, which on three systems compared as follows: horses, 12·70d. per car mile; electricity, 8·45d. per car mile; cable, 4·99d. per car mile.

Post Office Telephone Pipes.—The Highways Committee of the London County Council reported on Tuesday as follows: "An application has been made on behalf of the General Post Office for the Council's consent to the laying by the Department of a line of 4in. trunk telephone pipes from the Victoria-embankment subway, across Westminster Bridge, and along the Albert-embankment. That portion of the application which relates to Westminster Bridge will be dealt with by the Bridges Committee; and as regards the Albert-embankment, we see no objection to what is proposed. We therefore recommend that permission be given to the Post Office authorities to place a line of 4in. trunk telephone pipes under the footway on the river side of the Albert-embankment, upon condition that the work be carried out under the supervision of the chief engineer of the Council, and that any damage that may be done in the execution thereof be made good by, or at the sole cost of, the Post Office authorities, to his satisfaction."

Luton.—The town clerk has reported that the Luton Gas Company have lodged a petition against the Luton Corporation Electric Lighting Order (No. 2 Bill), that he had had a conference with the parliamentary agents in reference thereto and generally on the whole question, that if the Town Council desired to go on with and support their order it would be necessary to engage counsel, probably an expert, and submit evidence before the Select Committee to whom the Bill would be referred by the House, and that it was necessary for him and the parliamentary agents to receive instructions upon the whole subject at an early date. The town clerk further reported that it was impossible to state what would be the costs in supporting the order, because at present it was impossible to say whether the opposition would be strenuous or otherwise. After considerable discussion, it was resolved that, in consequence of the importance of the subject, the Town Council, sitting in committee, do consider and decide what steps and course of action shall be taken in the case.

Telephony in India.—The *Indian Engineer* says: "The advantages afforded by telephonic communication are too obvious to require any advocacy on our part, and we have often marvelled at the want of enterprise which limited the benefits of the instrument to the large cities only, and even then to a very limited degree. To our minds the wires should have long ere this been carried to the towns neighbouring to Calcutta, especially to those where jute, cotton, and other industries exist. To the tea planter a telephone installation, if carried out fully, would place him in instant speaking communication with all his coolie lines, and much of the danger which, owing to the isolation inherent to the industry, is now ever present as part of a planter's life, would be eliminated. We are therefore gratified to notice that Mr. John B. Saunders, the lately arrived general manager of the Bengal Telephone Company, Limited, of Calcutta, has turned his attention to this subject. We have little doubt that the enterprise of the company in this direction will be speedily availed of, the more readily so when it is found that the cost of telephone installations, as are now offered, are exceedingly moderate, and are far outweighed by the advantages which must accrue therefrom."

Yarmouth.—A meeting of the Town Council has been held, at which Mr. Martins said they had every reason to be satisfied with the good progress being made with the lighting of the town. The number of applicants for the electric light was keeping up well, and as the plant was only laid down for 6,000 lights and some 4,000 were now in use, it became needful to have an enlarged plant. Mr. Preece was very well satisfied with the progress made in three and a half months. The street-lighting would not be so profitable as the shop-lighting, and the more they got of the shops the sooner would the town be lighted throughout. A lengthy report by Mr. Preece was then read. In it he said: "The development has been quite equal to anything you could have expected. Most of the electric works in the country are now paying their working expenses, a fair interest on the capital expended, and proper allowances for sinking fund or depreciation; and the progress you have made will, I am sure, not place your works among the exceptions, especially when you take into consideration the remarkably small capital outlay at which they have been installed." The Council decided to apply for a loan of £15,500 to carry out the proposed works.

Digitized by Google

Morecambe.—The District Council have held a meeting at which Mr. Gardner said a committee had been formed to confer with the electric light company, and he would like to ask whether there was any report on the matter. Mr. J. Brown said the secretary of that company had promised great things, but nothing had been settled. Mr. Harper said a letter had been received from the electric light company, which stated that as most of the members of the Council were in favour of purchasing it, there was a favourable opportunity for so doing. The directors were asked to meet the committee, but only the consulting engineer's report was sent, which recommended an outlay of about £4 000 or £5,000. The secretary promised to send the auditors' report and balance-sheet, and also answer any questions the committee required, but there had been no reply nor had there been an official balance-sheet. He considered it very unbusinesslike. The Morecambe Electric Light Company announce the issue of 2,000 £1 5 per cent. preference shares for the provision of a new generating station, etc.

Applications for Provisional Orders.—The Highways Committee of the London County Council reported on Tuesday as follows: "On February 12 last, the Council directed that it should be suggested to the Board of Trade that in the orders for which applications had been made this year by the County of London and Brush Provincial Electric Lighting Company in respect of (*a*) Battersea, (*b*) Newington, and (*c*) St. Olave's district, the following words should be inserted: 'provided always that nothing in this order shall be held to authorise the undertakers to construct in or under the surface of any public street or place, chambers or receptacles for transforming apparatus of greater span than 3ft. and more than 2ft. 6in. in depth.' Of these applications, the first two have been withdrawn; and, with regard to the last, relative to the St. Olave's district, the Board of Trade has intimated that it thinks it undesirable to limit in the order (which can only be amended by a further order) the precise size of transformer-chambers, and is therefore unable to insert the clause suggested by the Council. We do not see that, having regard to the opinion expressed by the Board of Trade, anything more can be done by the Council with reference to this order."

Snowdon Mountain Tramroad and Hotels Company, Limited.—This Company was formed in November last for the purpose of (1) constructing and working a tramroad about 4¾ miles in length from Llanberis to a point at the summit of Snowdon; (2) acquiring a lease of and carrying on the Victoria Hotel. Llanberis, situated near the commencement of the tramroad; (3) erecting, furnishing, and carrying on the Summit Hotel at the upper terminus of the tramroad, 3,500ft above sea level. The capital is £70,000 in £10 shares and the issue is announced of 6,343 shares and £20,000, part of an issue of £35,000 4½ per cent. first mortgage debentures of £100 each. The list opened yesterday, and will close on or before Wednesday, 29th inst. The prospectus states that it is anticipated that the tramroad will he completed and equipped and ready for passenger traffic during the present season. The present issue of debentures is made to meet the expenditure upon the hotels, lands, and other matters not included in the contract for the tramroad works, the balance to be issued only if and when required. Shareholders will be preferentially considered in the allotment of debentures. The issue of shares is made at the request of the contractors, who have entered into underwriting agreements as to the subscription of the greater portion of the shares.

The Theft from the Brush Company.—At the Old Bailey on Monday, before the Common Serjeant, Horace Richard Eve, 21, clerk, pleaded guilty to stealing £237 10s, the money of the Brush Electrical Engineering Company, Queen Victoria-street. Mr. Campbell prosecuted. The prisoner had been for about six months a clerk in the employ of the company, whose premises were broken into under mysterious circumstances during the Easter holidays. The safe was opened with a duplicate key, but the cash-box was forced open, and the money in question was stolen. The premises were under repair at the time, and workmen were engaged there, and the prisoner, who was not suspected for some days, continued to perform his duties, but Sergeants Bryan and Oates seemed to have interrogated him rather closely, with the result that he (prisoner) disappeared. A report was publicly circulated that he (prisoner) had met with foul play, and nothing was heard of him until he was arrested in Aberdeen, when he boasted to the officer of the riotous kind of life he had had with the money, and the champagne dinners he had indulged in. He had spent a considerable sum of money on cab hire, some of the money he had lost in gambling, and some he had lent a friend. Prisoner had been convicted of forgery previously. The Common Serjeant sentenced the prisoner to 18 months' hard labour.

Ulverston.—The Rural District Council have held a special meeting to receive the report of the interview with the Board of Trade with reference to the Windermere and District electric lighting provisional order, and, if so determined, to rescind the resolution of the Council with respect to purchase by the local authority, and to pass further resolutions thereon. The Clerk (Mr. Dean) said after the last meeting of the Council Mr. Hodgson and himself proceeded to the Board of Trade, and had an interview with respect to Clause 59, which set forth the terms on which the local authorities might purchase at the end of 10 years. The objectionable portion of the clause, as altered by the Board of Trade, was "that no such sale shall be valid or binding unless the consent of the Board of Trade has been previously given thereto." The Council and the other bodies interested had thought this was binding them to something they did not approve of, but after some discussion they came away from the interview satisfied that the action of the Board of Trade would be rather favourable to the local authorities than to the promoting company, and therefore they thought the clause should stand. Mr. Poole, however, had suggested the addition of words to the effect that the agreement to purchase should be subject to such alterations and modifications as the Board of Trade might on such sanction being applied for determine to be just and reasonable. That would enable the Board of Trade to make any modifications that might be called for by the change in the production of electricity. Mr. Haines formally proved that the former resolution of the Council be rescinded, which was seconded by Councillor Kennedy and agreed to Councillor Haines further moved that the clause as altered by the Board of Trade be agreed to, with the suggested addition of the words proposed by Mr. Poole. Councillor Hall seconded, and it was approved of.

Coventry.—At a meeting of the City Council, Mr. Drinkwater asked when the electric light was to be given, and said people had the idea that it would not be available this year. Alderman Hill said there was no justification for the idea. There would shortly be a meeting of the committee The site of the electric light works is close to the west bank of the Coventry Canal. The necessary buildings have been recently erected, from the plans of Messrs. G. and I. Steane by Mr. C. J. Hill, and with Mr. Crawford as clerk of the works. The building consists of an engine-house 78ft. by 120ft, with chimney shaft, coal-stores, pumping-room, suite of offices, men's room, lavatory, and other accommodation. The engine-room is lighted by large windows at the sides, on higher and lower levels, and by clerestory windows, and also by a glazed lantern running down the entire length, with casements opening for ventilation. The buildings have slated roof and terra cotta dressings; in the engine-room the windows have cast iron frames and a wood-block floor is laid. The works were begun in August last, the amount of the contract being £6,800. The electrical equipment of the station is proceeding rapidly. Messrs. J. Fowler and Co., of Leeds, have a gang of men now employed, and it is hoped that the machinery will be running two months hence, although another month may elapse before the light will be available for the public. The boilers are in position and the engines are being erected. The high-pressure alternating-current system has been adopted, with low-pressure distribution. The present building is sufficient for considerable extensions of plant The plant at present being erected will be capable of producing current for 5,000 8-c.p. lamps. The work is being satisfactorily carried out under the supervision of Mr. G S Ram, who is acting on behalf of the Corporation, under the direction of Mr. Hammond, consulting engineer. At present the scheme does not embrace any public or street lighting. On the recommendation of the General Works Committee of the Town Council, it has been resolved to consent to the substitution of the Westinghouse system for the Thomson-Houston system in the equipment of the Coventry and district electric tramways.

Brighton.—A meeting of the Town Council was held on Thursday last, at which the Lighting Committee, in a special report, submitted tenders which had been received for the supply and erection of boilers and of vulcanised rubber and lead covered and armoured cables. As to these tenders, the committee stated that they were advised that a considerable saving at the electricity generating station would be secured by the use of boilers of the Babcock and Wilcox type, and they therefore recommended that the tender of Messrs. Babcock and Wilcox, Limited, to supply and erect three boilers of the total steaming capacity required at the Corporation electricity generating station and all other work in connection therewith for £3,100 should be accepted, and also that the tender of the British Insulated Wire Company, Limited, to supply vulcanised rubber and lead-covered and armoured cables at £230 per mile for three-core cable and £215 per mile for two-core cable, should be accepted. Councillor Berry, in moving the adoption of these recommendations, said the committee had in this taken the advice of their engineer, who had informed them that these boilers were largely in use at electric lighting stations, and that the three boilers, which possessed a capacity equal to six others, also enabled them to effect an economy in regard to the space that they would occupy in the works. The motion having been seconded, Councillor Broadbridge expressed a conviction that the committee had made a great mistake in not accepting the tender of Messrs Fleming and Ferguson to supply six of their boilers for £2,760, which was something like £340 less than the amount of the tender recommended, observing that the boilers supplied by the firm named had the highest reputation in the country. Councillor Horton Stephens said it was quite clear that in order to carry out their business the Council must incur this expense, and there was no doubt that the boilers chosen were the cheapest and enabled them to economise space and buildings. Councillor Evans supported the committee, remarking that he had more confidence in Mr. Wright's judgment than in that of Councillor Broadbridge in regard to the boilers. The report was then agreed to. On Monday the Lighting Committee reported that since the meeting of the Council at which the tender of the British Insulated Wire Company for the supply of vulcanised rubber and lead-covered and armoured cables was accepted, they had received a communication from the company stating that they had made a mistake in their tender, and asking permission to withdraw their offer for the supply of the cables The committee recommended that the British Insulated Wire Company should be allowed to withdraw from the contract, and that the tender of Messrs. Siemens Bros. and Co., Limited (which was the next lowest), be accepted at the prices named in their tender—viz., £289 per mile for three-core cable and £239 per mile for two-core cable.

PROVISIONAL PATENTS, 1895.

MAY 13.

9406. **Improvements in electric switches.** George Hill, 70, Market-street, Manchester.

9429. **Improvements in apparatus for electrolytical purposes.** Herbert Guthrie, 46, Lincoln's-inn-fields, London.

9433. **Improvements in electrically signalling on locomotives and apparatus for that purpose.** Robert Burn and Leonard George Tate, 28, Southampton-buildings, Chancery-lane, London.

9442. **Improved means for insulating electric conductors.** George Gatton Melhuish Hardingham, 191, Fleet-street, London. (The firm of Felten and Guilleaume, Germany.)

9445. **Improvements in electric meters.** Albert Peloux, 11, Southampton-buildings, Chancery-lane, London.

MAY 14.

9478. **Improvements in heating and cooking by means of electricity.** Gilbert Scott Ram, 23, Warwick-row, Coventry.

9504. **Improvements in shades or reflectors for incandescent electric and other lamps.** Alfred Allen Barratt and the Artistic Letter Company, Limited, 57, Chancery-lane, London.

9513. **Improvement in electric lamps.** William Henry Sheppard, 52, Chancery-lane, London. (Complete specification.)

9515. **Thermo-chemical processes for generating electricity.** Robert Dunlop Cassells and George Dowie, 14, Lewisham High-road, New Cross, London.

9521. **A photographic telegraph recorder.** John Imray, 28, Southampton-buildings, Chancery-lane, London. (Ader's system.) (La Société Industrielle des Telephones and Clement Ader, France.)

9546. **Improvements in or relating to conduits for electric railways.** Eduard Lachmann, 45, Southampton-buildings, Chancery-lane, London.

9547. **Improvements in and relating to the attachment of an electric lamp to a cap or the like.** Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Alfred Rodriquez and Edward Dayton Rockwell, United States.) (Complete specification.)

MAY 15.

9582. **Improvements in electrical apparatus for transmitting signals between points or stations, such as street fire-alarm apparatus.** Egerton Goolden Pulford, 10, St. George's-crescent, Liverpool.

9636. **Improvements in electric arc lamps.** Siemens Bros. and Co., Limited, and Frederick Booker, 28, Southampton-buildings, Chancery-lane, London.

MAY 16.

9683. **Improvements in apparatus for lighting railway carriages by electricity.** Robert Bell, 62, St. Vincent-street, Glasgow.

9684. **An improved commutator.** William John Harling, 4, St. Ann's-square, Manchester.

9685. **An improved brush-holder for dynamo-electric machines and motors.** William John Harling, 4, St. Ann's-square, Manchester.

9695. **A new or improved hand electric gas lighter.** John Sibley Richardson and Samuel Jevons, 77, Colmore-row, Birmingham.

9698. **Improvements in electrically-driven pumps and in apparatus therefor.** Charles B. Crawshaw and Rankin Kennedy, Hubert-street, Leeds-road, Bradford.

9704. **Improvements in electric track switches.** Joseph Young Porter, 321, High Holborn, London. (Complete specification.)

9708. **Improvements in electric heaters or rheostats.** James Henry Delaney, 23, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, November 23, 1894, being date of application in United States. (Complete specification.)

9727. **Improvements in and relating to telephones.** Sir Charles Stewart Forbes, Bart., 45, Southampton-buiidings, Chancery-Lane, London.

9730. **Improvements in electric igniting apparatus for gas and oil lamps and burners.** James Tarbottom Armstrong, 45, Southampton-buildings, Chancery-lane, London.

MAY 17.

9779. **An improvement in secondary batteries.** William Mather, 28, Southampton-buildings, Chancery-lane, London.

9784. **Improvements in electrodes, pencils, filaments, or the like for electric lamps of all kinds.** Fernand Le Roy, 6, Lord-street, Liverpool. (Complete specification.)

9796. **Improvements in conduits for electric cables.** John Bonthron, William Hart, and James Sherren Lucas, 24, Southampton-buildings, Chancery-lane, London.

9806. **Improvements in diaphragms for use in electrolytical apparatus.** Roger Comboul, 46, Lincoln's-inn-fields, London.

MAY 18.

9816. **Electric carriage-wheel contact.** Edwin Robinson, 5, Glossop-buildings, Moston-lane, Failsworth, Manchester.

9850. **Improvements in electrical switches.** Charles Mark Dorman, Reginald Arthur Smith, and Herbert George Baggs, Ordsal Electrical Works, Salford, Manchester.

9864. **An improved automatic safety clutch applicable to the suspension of electric arc lamps and for other purposes.** Robert Cornelius Quin and George Joseph Phillpott, 18, Hamilton-road, Brighton.

9882. **Improvements in and connected with conduits for electric light wires and the like.** The Safety Tread Syndicate, Limited, Joseph Mason, and Jonathan Mason, 55, Chancery-lane, London.

SPECIFICATIONS PUBLISHED.

NOTES.

Exhibition of Railway Appliances.—This exhibition, at the Imperial Institute, will be opened to-morrow (Saturday) at noon.

Fire at the Prague Exhibition.—The annexe of the exhibition at Prague containing the electric lighting machinery was burned down on Thursday last week.

Telegraphy in Warfare. — The Indian papers recently to hand speak highly of the telegraphic arrangements made in connection with the Chitral expedition.

Baltic Canal.—The German Emperor's marquee at Holtenau is to be constructed after his Majesty's own design. The dining-hall will be lighted by 150 electric lamps.

Waterloo and City Railway.—The Institution of Junior Engineers will pay a visit on Tuesday next, at 6 p.m., to the works in connection with this electric railway.

Eccentric Behaviour of the Electric Light.—According to Dalziel's Agency, a fire was caused last Friday night at the Comédie Française Theatre, Paris, "by the bursting of an electric light."

Forthcoming Book.—Mr. Gisbert Kapp has arranged with Messrs. Whittaker and Co. for a translation from the German of his new work on the alternate-current transformer. It will be published in the specialists' series in the autumn.

Telegraphy in Burma.—The Rangoon correspondent of the *Times* telegraphs that rapid progress is being made with the road and telegraph line to Keng-tung. The Shan chiefs are rendering valuable assistance. Both works will be finished by the middle of June.

Electric Motors on the Stage.—Some ingenious electrical contrivances have been placed in the Court Theatre in Monaco with a view to the more efficient and rapid performance of the work usually done by hand power. The current is taken from the electric lighting plant.

Electric Railways —A cablegram from the United States says that the Manhattan Elevated Railroad Company, which works the New York City elevated roads, has decided to change its motive power to electricity, and is selling an issue of Manhattan Consolidated bonds in London in order to provide funds.

Chinese and Burmese Telegraph Lines.—There has been presented to both Houses of Parliament a pamphlet forming No. 9 of the treaty series, giving particulars of the convention between Great Britain and China respecting the junction of the Chinese and Burmese telegraph lines, which was signed at Tien-tsin on September 6 last.

Telegraph Service Estimates.—The 1895-96 estimates for Civil Services and Revenue Departments were issued on Tuesday. A further sum of £3,890,050 is required to be voted on account for the Civil Services, and a sum of £1,430,000 for the Revenue Departments. The items under the last-named head include Post Office Telegraphs, £450,000.

Institution of Electrical Engineers.—The meetings of the Institution will be discontinued until the autumn. We are in receipt of the May issue of the *Journal* of the Institution, which contains, among other matter, Mr. N. S. Keith's paper on "The Electrolysis of Gold," and Mr. W. Langdon's on "The Employment of the Electric Light for Railway Purposes," with the discussions thereon.

Safety Rules for High-Tension Currents.—One of the duties of the forthcoming congress of German electrical engineers at Munich will be to consider an elaborate code of safety rules for high-tension currents which has been jointly prepared by the Verband Deutscher Elektrotechniker and the Elektrotechnischer Verein, and which is printed in the organ of these societies, the *Elektrotechnische Zeitschrift*, for May 23.

Electric Traction in Turin. — M. Gruslin, of the Società Belga delle Tramvie di Torino, is, it is said, about to receive a concession from the municipal authorities of Turin for the construction of an electric tramway in that city on the trolley system to replace the existing horse traction. It is proposed to employ motors of 25 h.p., which will give the cars a speed double that of the present trams. The new plant is estimated to cost 1,200,000 lire, or £48,000.

Electric Light for Mines.—Mr. Hall, inspector of mines in the Liverpool district, is strongly in favour of electricity for lighting, though he points out that a portable and thoroughly satisfactory miners' lamp is still to be invented. He does not consider the objection that an electric lamp would not afford any test as to the state of the atmosphere of a mine worth consideration, because such a lamp gives so much security compared with any of the safety lamps of the well-known patterns.

North-East Coast Institution.—We have received the May issue of the *Transactions* of the North-East Coast Institution of Engineers and Shipbuilders, which contains the adjourned discussion on Mr. W. C. Mountain's paper on "The Design and Efficiency of Plant for the Transmission of Power by Electricity," and Mr. Mountain's reply; discussion on Mr. Henry Foster's paper on "The Application of the Electric Arc to Machinery and Boiler Repairs"; and a paper on "Turret-Deck Cargo Steamers," by Mr. S. O. Kendall.

The Electric Light in Russia.—The various buildings of the Kremlin, in Moscow, are, in view of the forthcoming coronation of the Tsar, to be electrically lighted by means of 2,000 16-c.p. incandescent lamps and 40 arc lamps. Messrs. Schuckert and Co., of Nuremberg, who are to provide this installation, have been particularly fortunate in securing Russian contracts for electrical work—for example, the lighting of the Imperial Palace at Gatschina, the Marien and Michael Theatres in St. Petersburg, and of the Imperial Grand Theatre in Moscow.

Electric Lighthouses in France.—The new lighthouse at Penmarch Point, Brittany, the thirteenth of those lighted by electricity on the French coasts, will be about 130 yards to the eastward of the present one. Its tower, which will be about 185ft. above high-water line, is being built entirely of the best description of granite, and the light will be of such intensity as will, it is said, enable it to be seen at a distance of nearly 100 miles in clear and from 25 to 28 miles in hazy weather, having an illuminating power of 10,000,000 candles.

The Lalande Microphone.—M. de Lalande has constructed a microphone, to the carbons of which he applies the system generally used in physical instruments to deaden the oscillations. This system consists in immersing in a liquid the oscillating or vibrating portions, or parts which are rigidly connected to them. To this end the carbons of the new microphone are furnished with pieces of ebonite dipping into a bath of mercury likewise in contact with the sounding-board. The mercury, it is asserted, deadens the vibrations of the diaphragm and the carbons.

"Franklinisation."—M. H. Bordier was the author of a note, entitled "Action of the Static Sparks on the Local Temperature of the Regions subject to this mode of Franklinisation," which was read at a recent

Digitized by Google

meeting of the Académie des Sciences. *L'Industrie Electrique*, in referring to this communication, remarks that its nature does not permit of even a brief abstract being made of the paper, and then slyly pokes fun at the authors of "such antiquated and ridiculous terminology as Franklinisation, Faradisation, Galvanisation, and d'Arsonvalisation."

Electric Dispersion.—Mr. P. Drude, in *Wiedemann's Annalen*, describes a method for investigating the relation between the dielectric constant of a substance and the period of the electric waves traversing it, or what may be described as the electric dispersion of the substance. If the dielectric constant decreases as the period increases, there will be normal, if it increases, anomalous dispersion. For alcohol dispersion was found to be normal, and of the same order of magnitude as its optical dispersion. Water showed abnormal dispersion with the large wave-lengths used, whereas ebonite showed no perceptible dispersion.

Church Electric Lighting in Italy.—Considerable interest has apparently been manifested in Italy in the fact that the church of the Corpus Domini in Bologna, in view of a three days' congress which was to be held within its walls, was illuminated by electricity. Two 2,000-c.p. arc lamps lighted the body of the sacred edifice, converted for the nonce into a secular building, while the various corridors were fitted with 16 c.p. incandescent lamps. The current, which was furnished by a dynamo driven by a small steam-engine placed in a building some 60 yards distant, was divided into three circuits—one for each arc lamp, and the other supplying the incandescent lamps.

Electric Traction in France.—Some surprise has been expressed in France that a Belgian firm—the Société Anonyme d'Electricité (Bouckaert et Cie.), of Brussels—should obtain the contract for the conversion of the existing horse tramways in Toulon, some 10 miles in length, into electric lines. This company will supply 30 cars, each fitted with two 15-h.p. motors. There will be three dynamos in the station, each of 200 h.p. and having an output of 132 kilowatts at 400 revolutions a minute. The three steam-engines will be single-cylinder horizontal; the boilers semi-tubular. Overhead conductors will be employed, the return being by the rails.

Personal.—The Queen has conferred the Knight Commandership of the Indian Empire on Mr. William Robert Brooke, late Director-General of Telegraphs in India.—Mr. W. T. A. Emtage, M.A., of Pembroke College, Oxford, now professor of mathematics and physics in the University College, Nottingham, has been elected principal of the Wandsworth Technical Institute.—The Victoria University, Manchester, conferred honorary degrees for the first time on Wednesday. Among those honoured was Lord Kelvin. In the evening a banquet was presided over by Dr. Leech (chairman of the convocation), at which Lord Spencer (chancellor of the University), Lord Ripon, and Lord Kelvin spoke.

Long Telephone-Wire Span.—The telephone wire which has recently been stretched across Lake Valen, in Switzerland, is claimed to supply the longest clear span in the world—namely, 8,000ft. It connects Quinten, which nestles at the foot of the Leistkamm, with Murg. At the former place the wire touches land at a height of nearly 1,200ft. above the sea-level; at the latter it is fastened at an elevation of 430ft. Hitherto, in Switzerland, the longest wire span has been only 3,050ft. The wire, which at the lowest point is 140ft. above the surface of the lake, is 2mm., or 0·079in. thick. One large vessel and 16 small craft were engaged in the operation of placing the cable between the points mentioned.

Curious Accident.—A Welsh paper states that Mr. Harry Baskerville, of Carmarthen, lineman of the Postal Engineering Department, and his assistants were shifting a telegraph post and fastening a wire to a chimney near the Bridge Shop, Llandyssul, on Monday, when the wire snapped, pulling him after the ladder and swinging him clean over the house-top. In the act of falling he shouted to a man who was directly under him, "Look out below!" which caused that man to clear away, and he thus escaped serious injury. Mr. Baskerville had the presence of mind to prepare himself for the fall, and, landing on his side and hand, he escaped with a slight fracture on his forearm.

Rival Illuminants.—The Dresden Electrotechnical Society have held a joint meeting with the Prometheus Institute to hear a paper by Prof. W. Wedding on the latest advancements in lighting. The paper dealt mainly with acetylene, which he stated was cheaper than the incandescent gaslight. Touching upon electric lighting, he held that little progress had been made of late years in connection with the incandescent lamp. Arc lamps, which formed the most brilliant of any light, were not suitable for small candle-powers—an observation not very remarkable for originality. He, however, admitted that they were admirably suited for street-lighting and far superior to incandescent gas lamps.

The Therapeutic Action of Currents of High Frequency.—It is known, *L'Eclairage Electrique* remarks, that M. d'Arsonval has introduced into electrotherapy new processes of electrisation based on the employment of currents of high frequency. MM. Apostoli and Berlioz have been experimenting for over a year with one of his methods, self-conduction, upon 65 invalids, and they have come to the following conclusions: currents of high frequency, when they completely envelop the patient and act by self conduction, are inefficacious and impotent against the majority of hysterical troubles and against certain neuralgic complaints, but the same currents exercise a powerful influence on the nutritive energy.

Cutting Hair by Electricity.—To have your hair singed off by electricity is the latest development of the tonsorial art, says an American contemporary. The apparatus to perform this operation consists simply of a platinum wire stretched over a comb. By pressing a button in the handle of the comb current is applied to the wire, and it is heated to a white heat. The comb is passed through the hair, and as the wire comes in contact with the hair it is burned off, the end of each hair being cauterised as cut, which process prevents the loss of the oily substance with which the hair is filled. The apparatus is connected by flexible cord and attachment plug to a lamp socket, and can be used by any barber of ordinary skill.

Electricity at the Amsterdam Exhibition.—At the international exhibition in Amsterdam, which was opened a fortnight ago and will close in November, electricity figures in the second section of group II. under the following divisions: Electric light—arc systems: apparatus, lamps, and accessories; incandescent systems: apparatus, lamps, and accessories. Electric motors—tramways, underground mine railways and others. Various applications of electricity—galvano-plastics (galvanic silvering, gilding, and nickeling); materials and methods for welding iron, steel, and other metals; methods of transmission and of indication; alarms; telegraphic apparatus; railway signals; cables, wires, and insulators; electric batteries; dynamos.

Technological Exhibition.—A seven days' exhibition of specimens of the practical work of candidates at the technological examinations, held this month in connection with the City and Guilds of London Institute for the

Digitized by Google

Advancement of Technical Education, was opened last Saturday afternoon at the Imperial Institute. The exhibition, which is the second of its kind, comprises specimens of cloth and cotton weaving, dressmaking, metal plate, plasterers' and plumbers' work, mechanical engineering, carpentry and joinery, cabinet-making, and bookbinding. The examinations have now been held for 17 years, and the work is mostly done in workshops attached to schools or factories all over Great Britain, and, to some extent, in Australia, New Zealand, India, and South Africa.

Mason College, Birmingham.—A notice has been issued concerning three Priestley Scholarships in Chemistry, two Bowen Scholarships in Engineering, and one in Metallurgy, which were founded by the late Mr. T. Aubrey Bowen, of Melbourne. They are intended to encourage and afford facilities for the higher study of these subjects in Mason College, where they are tenable for one year, with the possibility of renewal at the discretion of the council of the college. The annual value of each is £100. Although, naturally, good work done at Mason College will be regarded as a specially favourable qualification, the council have thrown all the scholarships open to general competition. The first award will be made in September next, and all particulars may be learned on application to the secretary of the college.

Spiral Wall Socket.—Heretofore, when brackets or other fittings have been fixed to brick or plaster walls it has been necessary to drill a hole in the wall with a chisel, plug this with wood, and then use the latter as the support for the object intended to be fixed to the wall. Mr. Julius Boeddinghaus, of Dusseldorf, Germany, has recently brought out a novel device for the ready adjustment of brackets of all descriptions. It consists in embedding in the wall, while the plaster is being applied, a metal spiral. When the wall is finished the spiral is firmly held in position and can easily be cleaned out. It then forms a socket into which the bracket can be readily screwed and held firmly. The device not only saves time, but does not ruin the walls, carpets, or ceilings, while at the same time offering an absolutely rigid hold for the bracket or other device. It naturally also allows of a ready removal of the bracket.

Rapid-Fire Electric Gun.—An electric gun has been invented by Mr. A. S. Krotz, electrician of the Springfield Street Railway, U.S.A. It is simply a brass tube, open at both ends, around which is wrapped insulated wire, in a series of helices from one end to the other, acting upon iron balls put in at one end of the tube and passing through with ever-increasing impetus. The special advantages claimed for the gun are that it may be made very light in proportion to its capacity for throwing balls; that it cannot possibly explode; that it is economical in operation; and that the limit of the number of balls it will throw within a given time is the number of balls that can be put into its breech. For field service it is claimed it will far surpass anything now in use. The inventor estimates that from 700 to 1,000 shots per minute can be fired. Tests have been already made that are said to have been highly successful.

Photography by Electric Light.—On the occasion of a representation of "Harischandra" by Mr. Balivala's company, at the Novelty Theatre, Bombay, in honour of the Hon. Mr. Pherozeshah M. Mehta, Mr. Shapur N. Bhedwar, says the *Indian Engineer*, took a photograph of the whole audience by means of electric light. The mode adopted by this gentleman was that he used 21 arc lamps of 2,000 c.p. each. A row of 10 lamps was placed at the front end of the stage, on the top of the proscenium, while two lamps were placed almost touching the stage in order to counteract the shadows of the top lamps. In addition to these, on the right-hand side of the dress circle a row of six lamps was fixed in step fashion—that is, the highest lamp at the back and the lowest in front. Similarly, in order to counteract the shadows of these lamps, two other lamps were placed on the left-hand side of the dress circle, and one lamp was hung in the centre of the theatre on the extreme top. Some idea of the extent of the lighting may be obtained when it is stated that the area of the theatre is about 350 square yards, and has sitting room for 1,200 people. The lamps were lent for the occasion from the electrical department of Messrs. Nowrojee Wadia and Sons, and by Mr. J. N. Tata. The whole of the installation was erected under the direction of Mr. Bhedwar by Mr. Jehangir Nowrojee Bellihomjee, a well-known electrician of Bombay.

Magnetism of Volcanic Rock. — Signor G. Folgheraiter is the author of an article in vol. iv. (1895) of the *Atti* of the Accademia dei Lincei, entitled "The Induced Magnetism of the Volcanic Rocks of the Terrestrial Magnetic Field." He has conducted experiments on volcanic rocks with the object of determining the quantity of magnetism induced in them after having been heated to such a temperature as to entirely lose their permanent magnetism in the case of both slow and rapid cooling, and he hopes to be able to deduce from these observations conclusions relative to the conditions under which the rocks were remagnetised that were permanently magnetised. The pieces of rock which were experimented with were cut into the form of small parallelepipedons, weighing about 50 grammes, and whose length was twice or thrice that of their other dimensions. Care was also taken that they were cut in the direction in which the original rock stood. The specimens of basalt examined, the author said, might be divided into two groups: (1) those which were primarily only weakly magnetised, and in this case, after heating to redness, the magnetisation always augmented, but in different degrees, in the various specimens; (2) those basalts which were originally powerfully magnetised, and in this case, after heating, the magnetisation was considerably diminished. In both groups the magnetisation suffered no change during three months, and sudden cooling gave the same results as slow cooling.

A Simple Electric Chronograph.—Mr. Carl Barus, in the *American Journal of Science*, describes a simple chronograph pendulum which is likely to be very useful to those who have no break-circuit chronometer or seconds clock at their disposal. It is a simple mechanism by which an ordinary seconds pendulum is both kept in motion and made to record its oscillations on one or more chronographs sharply. The heavy metallic bob of the pendulum is electrically connected with the knife-edge, and its top is surmounted by a soft-iron armature, which is attracted during part of the swing by an electromagnet, and thus kept in motion. A longer and very much lighter pendulum, consisting of a flat bob suspended by two wires, is suspended by the side of the first, and swings in the same plane, but with a longer period. As the heavy pendulum approaches it, it touches a platinum spring projecting from the other bob, makes current for a moment, and works the chronograph, and at the same time sends the current through the electromagnet. The contact is quite momentary, as the spring causes the wire pendulum to be hurled off ballistically. On its return it is brought to rest, without rebounding, by a stop, against which it leans till the seconds pendulum returns. The bob of the light pendulum is made up of two small square parallel plates, between which the wires and the platinum strip are clutched by a single central screw. A band of platinum foil is wrapped round the

Digitized by Google

heavy bob in order to ensure reliable electric contact. The chronographs and the electromagnet are connected in parallel. The records show that the time of contact does not reach 0·1sec.

Electrical Competition.—The Société d'Encouragement pour l'Industrie Nationale offers some special prizes in the electrical industry and others. A premium of 2,000f. will be awarded in 1896 for a small domestic motor, working independently or connected with a central station, and having an output of from 6 to 20 kilogramme-metres per second. This prize has already been awarded four times: on the first occasion to a hydraulic motor, on the second to a steam-engine, on the third to a gas-engine, and on the fourth occasion to a system of house-to-house transmission of power. It is now desired to vary the form and system of the motors, so that it would seem that the society is anxious to see what electricity can do in connection with its offer. A premium of 1,000f. will be awarded in 1896, if it be earned, for a new alloy useful to the arts. The society is induced to hold out this prize for competition in view of the great results which have been achieved with aluminium, and of the possibilities that one or more of the newer metals may present of forming a useful and successful alloy. A premium of 2,000f. will be given in 1896 for an electric incandescent lamp of a decimal candle-power using 0·05 ampere at 100 volts. The object is to obtain a lamp of small illuminating power running at a high voltage. The last prize is one of 3,000f., which is offered for bestowal in 1897, for a treatise embodying important improvements on the present methods of producing permanent magnets. Competitors should forward their schemes, models, etc., to the Secrétariat de la Société d'Encouragement pour l'Industrie Nationale, rue de Rennes, 44, Paris, before December 31 of the year preceding the distribution of the premiums.

Deaths from Electricity.—Mr. A. J. Farnsworth, an American engineer, writes that it has been frequently pointed out that it is current, and not voltage, that kills, and that the human body is not at all like a voltmeter, or other device of constant resistance, which can always be placed across the terminals of the circuit for which it is intended. If we should attempt to name a voltage that is capable of being handled at all times, by all persons, and under all circumstances with impunity, we would be compelled to make it very low indeed. The writer would not dare place it above 50 volts, and deaths have actually occurred from contact with 50-volt circuits, although probably from leakage currents. On the other hand, many persons have received shocks from contact with circuits of several thousand volts without injury, and D'Arsonval cites the case of a man subjected to an E.M.F. of 2,000 volts for several minutes without any disagreeable results to speak of, beyond temporary unconsciousness. Of course, the reason for this great discrepancy is that the resistance of the body changes enormously under different conditions of contact. It is also exceedingly likely that different conditions of health in an individual render him at one time more likely to succumb to electric shock than at others. The writer is also convinced that deaths of persons shocked by electricity have been the result of fright and superstition. Recently a coachman was shocked from a 104-volt circuit, and, although he was entirely uninjured, it took several hours and many persons to convince him that he would not die. Pale and trembling, he expected each moment to be attacked by convulsions and other symptoms of the poison with which he apparently considered himself inoculated.

The Pollak Rectifier.—At a recent meeting of the Elektrotechnische Gesellschaft at Frankfort-on-Main, Mr. C. Pollak read a paper which treated of the various uses to which the arrangement that he has devised and denominates a *Gleichrichter*, or rectifier, can be put. The instrument, he said, was designed to charge accumulators by means of alternating currents and also, in conjunction with a battery, to give continuous currents, and his object has been to form out of the purely alternating-current system, by means of rectifiers and accumulators, a new composite method, with a view to restrict the size of central stations and to utilise them to the fullest possible extent. The switching, he continued, differed from the ordinary method in charging accumulators only in that the automatic switch is polarised so that it may immediately operate if the current should change its direction. The first installation of this kind in which rectified alternating currents for electrolytic purposes have been permanently used on a large scale was fitted up in the works of the author's firm. The municipal central station supplied all the energy required in the form of single-phase alternating currents at 3,000 volts. In the works the current was transformed down to 65 volts and then rectified. The current thus obtained served to charge accumulators as well as to run continuous-current motors, arc and incandescent lamps. There were four rectifiers for every 350 amperes required, of which two or three were incessantly, night and day, in operation. The rectifier needed no foundation and very little room and attention; in charging accumulators it did not require more oversight than a dynamo, as the brushes only had to be shifted at the commencement and towards the end of the charging. In working, Mr. Pollak stated, *in* conclusion, the current supplied by the rectifier differed in no way from the ordinary continuous current. The method is fully described and illustrated in the *Elektrotechnischer Anzeiger* of May 23.

Electric Gold-Dredging Plant.—An interesting account was given recently by Mr. Robert Hay, of the application of water power in producing electricity for use in gold dredging in Shotover River, New Zealand. The water is obtained at a creek 1½ miles distant from the dredging ground, and brought by a race cut in the side of the hill, or, in places where the ground is not suitable, in a timber flume to a pressure-tank at a level of 524ft. above the pipes at the generator-house. From this tank to the Pelton wheel the water is carried in rolled-steel pipes, constructed in lengths 19ft. 6in. bolted together by wrought-iron flanges riveted to the pipes. The prime mover of the generating plant is a 4ft. Pelton reaction waterwheel, upon the buckets of which the water, from a nozzle 1½in. in diameter, impinges at a pressure of 228lb. per square inch. This wheel drives two series-wound dynamos working at a normal speed of 700 revolutions per minute, each developing a current of 40 amperes, at an E.M.F. of 650 volts, or nearly 70 h.p. The dynamos are coupled in series. The conductors, of a length of two miles, are of No. 4 S.W.G. bare copper wire, and are supported upon insulators carried by cross-arms upon old 40lb. rails. The current is conducted to two motors in the dredge, one for driving a centrifugal pump and the other for operating the buckets, winches, and revolving cylinder. These two machines are duplicates of the dynamos, and are coupled in series, so that when the bucket motor is switched off, the pump motor absorbs the surplus power by increasing the speed of the pump, and causing it to throw more water. The dredge is constructed for the most part of steel, and is capable, when operating at a depth of 20ft., of an output of 90 cubic yards per hour. The dredgings are delivered through a revolving screen, for separating the stones and coarser material, upon baize tables set at an inclination of

Digitized by Google

1 in 12. Two 10-ampere arc lamps light the dredge at night, and are joined in multiple series with the motors, with suitable arrangements for their control. The cost of the installation and the weekly working expenses are £7,000 and £35 respectively.

Electricity v. Coal.—Mr. Sydney F. Walker discusses this question in a Welsh paper. He says: "It is quite true that in order to generate electricity you must consume some agent in which some other form of energy, and preferably heat, is stored, and of all possible agents coal is decidedly the most economical. But oil is rapidly taking the place of coal for a great many purposes. Where electricity will come in is in economising the consumption of coal and of oil by enabling very large engines and boilers to be used at convenient places, and also by utilising the at present wasted natural sources of energy, such as the rainfall, the rise and fall of the tide, the wind, and even the direct rays of the sun. At present it is cheaper to burn coal or oil, and to use the expensive energy of steam or gas, than the energy of falling water, of wind, or the direct rays of the sun, because the coal and oil can be consumed in any convenient spot where the work is to be done, while the other sources of energy are available only at inconvenient positions. But the practical development of transmission of power by electricity is gradually changing all that. The increase of the efficiency of electrical power transmission and the growing familiarity with higher and higher voltages are bringing the natural sources of power more and more within the limits of practical usefulness. Already the dream of generations of engineers, the utilisation of the energy of the falls of Niagara, is an accomplished fact, in part at least; the city of Buffalo, some 17 miles away, being lighted by electricity generated by the energy of the falling water, and some of its factories having their machinery driven from the same source. It is but the development of this, certainly a large development, but one that may possibly take place within the lives of some of the present generation, for us to be utilising the energy of Niagara in the same way in this country. Long before that goal is reached, however, coal will have to fight for its own existence as an industrial necessity."

Cable Routes.—On Friday last Lord Rosebery received a deputation from the Association of Chambers of Commerce in favour of inter-Imperial postal and telegraph routes between this country and the colonies, and between the colonies themselves, without such routes passing through other countries. The deputation was introduced by Sir Albert Rollit, president of the London Chamber, who expressed the desire of the chambers for a more close connection between the colonies and the mother country, which was one of their chief objects. With this view they approved most heartily of the result of the conference at Ottawa, and were of opinion that as the mail service to the United States was already heavily subsided, a similar Atlantic route to the Dominion of Canada itself should also be similarly subsidised. He pointed out the dangers our commerce might incur in case of war by the passage through possibly hostile countries of the means of telegraphic communication between the mother country and the colonies. The proposals of the chambers were for an Atlantic line and for a land route through the Dominion of Canada, and two Pacific lines, to Australia and New Zealand, which would bring them in close contact with China and Japan, a matter which it was impossible to overlook at the present moment. To show how greatly the colonies desired this, he might mention that the Dominion Government, which already paid heavily, would be ready to increase the present subsidy to £175,000. What they really desired was an Imperial postal mail subsidy. The vessels for this service would cost £400,000 each, and be 20-knot boats, and the saving of time would be 29 hours to Montreal and 24 hours to Vancouver. But in addition to Canada, the Australian colonies would also be largely benefited. He concluded by presenting a memorial on the subject. Mr. Plummer (Newcastle), as an ardent advocate of Imperial federation, regretted that the initiative in this matter had been left to the colonies themselves, and not taken up by this country. Lord Rosebery, in reply, said he had no decision on the part of the Government to announce. The Government had received Lord Jersey's report and referred it to a departmental committee, whose report has not yet been received. The Government had the matter practically under consideration, and hoped to be able shortly to give a satisfactory reply.

Electrical Trades Section.—A meeting of the Electrical Trades Section of the London Chamber of Commerce was held on Tuesday last, Mr. E. Garcke occupying the chair. The proceedings took the form of desultory discussions, and the attendance was very small. With respect to the special committee which had considered the telephone question, the Chairman said so many opposing interests were representing that the conclusions arrived at were mainly of the nature of compromises. Mr. Sydney Morse regretted that no one had represented the Chamber before the Parliamentary Committee from a purely commercial standpoint. Mr. Garcke said the question of light railways would be referred to a joint committee of the electrical and engineering sections. A committee has been formed of various trades in the Chamber to consider the Factories and Workshops Bill, and the chairman undertook to attend it on behalf of the Electrical Trades Section. The Crystal Palace and District Electric Supply Company, Limited, wrote complaining of the manner in which rates were fixed, and it was decided, on the motion of Mr. Garcke, seconded by Mr. Morse, that a strong representation be made to the council to take into consideration the existing law of rating with a view to its adjustment. The National Traction Engine Owners' and Users' Association wrote with respect to the section dealing with the subject of electric traction. It was stated that Major Flood-Page was looking after this matter. A new general committee has been appointed by the Chamber to deal with the question of merchandise marks. Mr. Sellon was appointed to act on this, and the chairman said he would find a second representative. The section had under consideration whether they should offer a prize or prizes in electrical or other subjects under the commercial education scheme of the Chamber. It was decided to take no action. Mr. Morse brought forward the fact that the Board of Trade were reducing the period of 42 years for metropolitan electric supply companies to 42 years from 1888. He approved of the orders lapsing at the same time, but considered that the companies should as an offset have better terms. It was agreed to write to the Board of Trade setting forth these views. Mr. Morse also drew attention to the fact that the traction protective clauses were not always inserted in private Bills as recommended by the Select Committee of 1893. It was agreed to write to draw the attention of the authorities to this matter. The last business to be transacted was the consideration of the revised Board of Trade electric light regulations. It was arranged to send out circulars to the electrical supply companies in London inviting suggestions with a view to an interview being held with the Board of Trade officials, and to write to the Board of Trade that this course had been adopted.

ELECTRIC LIGHTING OF TRAINS.—III.

BY R. W. WEEKES, WHIT.SCH., A.M I.C.E.

(Continued from page 588.)

MIDLAND RAILWAY COMPANY.

Although this company has now discontinued lighting its express trains by electricity, it has done so with regret, and the cause of the abandonment will be explained below. Mr. W. E. Langdon has from the first taken a lively and practical interest in the various methods of train-lighting, and his first attempt to light a train electrically will be of interest. The following is condensed from his remarks on the subject, in the discussion on Mr. Massey's paper before the Society of Telegraph Engineers and Electricians in 1884. A system of primary batteries was employed, the batteries being of the Holmes-Burke type.

A carriage, consisting of six compartments and a guard's van, was fitted with the incandescent light. There were two lights in one compartment, one light in each of the other compartments, and two lights in the guard's van. The battery was placed in the van. The wires were carried along the roof of the carriage, and the lamps were fixed in the inside of the roof in the same manner as were the ordinary oil lamps. The van was therefore capable of being uncoupled and coupled as required. The lamps used were of 5 c.p., and the illumination of the compartments was pronounced by Mr. Langdon to be very good, and a very great advance upon the oil lamps. Still, he thought improvements could be made. Although one could read very well in the compartment containing two 5-c.p. lamps, it was not so easy in the remaining compartments, which had only one 5-c.p. lamp.

The fittings of the first-class compartments absorbed very much more light than those in the third-class compartments, and that may have accounted for a better light being obtained in the latter. The battery consisted of 15 cells, three parts of five cells each. The E.M.F. of the battery was 1·85 volts, and its resistance was one-fortieth of an ohm per cell. The lasting power of the battery was said to be 10 hours. The battery received daily attention. The experiment was carried out in connection with the London and Bradford express, and the single journey occupied five hours five minutes. There was a certain time during which the light was made use of when the train went through tunnels; the consequence was that the light was not run economically. The liquid which kept the battery going had to be replaced daily. Mr. Langdon's experience with regard to the plates, so far as he was able to ascertain at that date, was that they required re-amalgamating about twice a week. The liquid employed was sulphuric acid (diluted 1 to 12) in the zinc cell, and a patent preparation, which Mr. Holmes termed oxydone, for the carbon cell. Fumes were given off by the battery, and it was necessary to carry them away. This was to a certain extent objectionable. In the experiment, the fumes were not found in any way to interfere with the comfort of those whose duties required their presence in the van. The experiment, so far as concerned the Midland Railway, was regarded only with the view of testing the applicability of the electric light to railway travelling, and, with respect to that, Mr. Langdon said the experiment was perfectly successful.

The question of cost he did not think it would be fair to go into upon so small an experiment. It was evident that the battery was run under exceptional circumstances, and was not at that time being used economically—a great portion of it being wasted. Mr. Langdon considered that the question of the cost as regarded lighting by a primary battery could not be dealt with until they had had some more complete experiments—*i.e.*, larger trains fitted. There was one point which it was perhaps desirable to draw attention to, and that was whether railway carriages should be provided with one or two lights in each compartment. His opinion was that no compartment should be without two lights, so that in the case of anything happening to one through the rupture of its carbon filament, or something else, there would be another lamp left to illuminate the compartment. If 10-c.p. or 20-c.p. lamps were used, that, again, would alter the arrangements for the source from which the lighting power was derived. Undoubtedly, the most complete way of lighting a train was for each carriage to carry its own source of light, but that was hardly possible when using the primary battery, for with primary batteries that require to be charged every day it would hardly be possible to take the cells out and replace them to the necessary extent. Also the question of the quantity of force that had to be provided must be considered, for whether it was a primary battery or whether it was a dynamo, a certain force would have to be provided for a certain number of carriages which would have to be lighted from that source. These were all questions which he imagined would engage the attention of those gentlemen who were engaged in attempting to introduce the electric light to railway travelling, but they were questions of moment, because there were no railways in the kingdom whose traffic was not subject to be broken up and put together in a very haphazard sort of manner. In some cases as many as eight or ten carriages might be found between the guard's van and engine, and in others perhaps only three or four carriages, and some system of controlling the power would be necessary. In the experiment on the Midland Railway they used a switch which was placed in the guard's van and under the control of the guard, who had the power of increasing or decreasing the battery power. He mentioned finally that, although the train had been running for nearly four weeks since the electric light was fitted, they had only experienced one instance of failure of the lamps, and that was due to the filament of one of the carbons being destroyed.

As is foreshadowed in the above, the primary battery system was not destined to be continued on the Midland Company's trains, and the question of electric lighting was held in abeyance till 1888, when the directors authorised Mr. Langdon to equip two trains to run between London, Manchester, and Liverpool. The first of these was ready in May, 1889, and the second followed shortly afterwards. One of them was wired upon what is known as the "parallel" system, and the other upon the "series" system—*i.e.*, in the former the lights and batteries were arranged in parallel, whilst in the latter the batteries were in series, the lights in each coach being worked from the cells carried by it. It is needless to say that this was done for the sake of comparison. The main advantage of the "parallel" system is that any deficiency in the electrical energy of one vehicle is wholly, or to a great extent, met by the efficiency of those adjacent to it—the one can borrow from the other. The main disadvantage of the "series" system is that a break in any part of the train—a loose connection, etc.—cuts off the charging circuit, and throws the entire onus of the lighting upon the batteries. But it is somewhat less costly, in that smaller conducting cables may be used. Experience speedily displayed the advantages of the "parallel" over the "series" system, and the arrangement of the second train was modified accordingly. In each case the electricity was generated by a dynamo driven by belting from the wheels of the guard's van.

The first dynamos were supplied by the Brush Company, and were similar to the machine described in my last article. The design and manufacture of subsequent dynamos was placed in the hands of Messrs. J. H. Holmes and Co., of Newcastle-on-Tyne, and I had the honour while with them to prepare the drawings for the first set made. The following is a list of what this dynamo had to do automatically:

(*a*) To switch itself into circuit when its E.M.F. had risen to the required value.

(*b*) The E.M.F. must afterwards be practically independent of the speed.

(*c*) An automatic reversing gear must be provided to reverse the connection with a change in direction of rotation.

Mr. J. H. Holmes decided to use a Gramme-wound armature, which has not the self-regulating properties of the Brush open-coil armature. The E.M.F. of a Gramme armature is proportional to the product of the strength of the magnetic field into the number of revolutions of the armature. If, therefore, the field strength can be decreased in the same ratio that the speed is increased, a constant

Digitized by Google

voltage will be obtained. To effect this, Messrs. Holmes arrange two dynamos, Q and R (Fig. 8), having their armatures upon the same shaft, so as to revolve together, but influenced by separate magnetic fields. Q is the main generating machine, the strength of the magnetic field of which is regulated by R. The magnets of both dynamos are separately excited from a set of accumulators, C (Fig. 9), those of Q being provided with two distinct exciting circuits. One of these is an ordinary high-resistance shunt

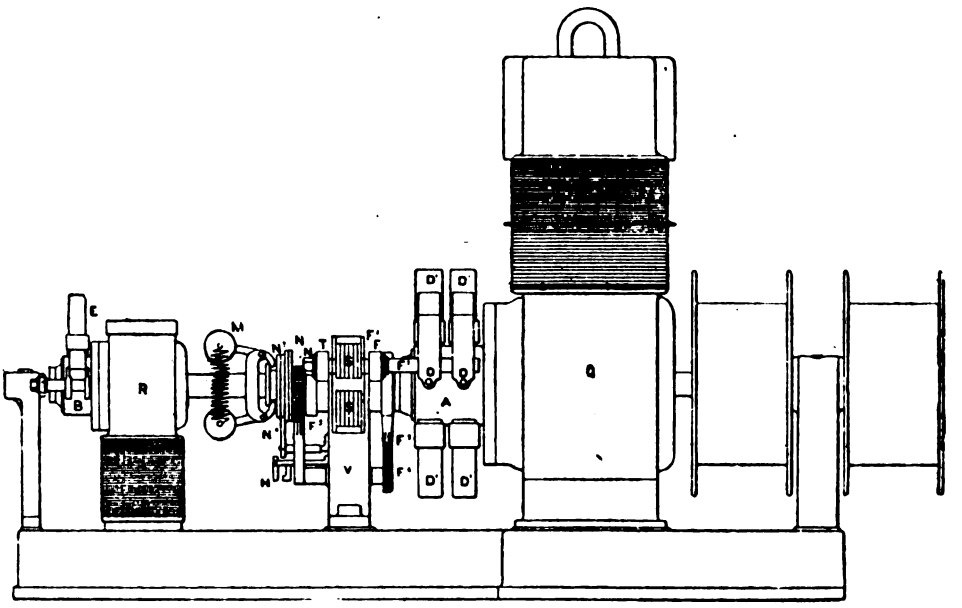

FIG. 8.—Elevation of the Holmes Train-Lighting Plant.

circuit connected to the accumulators, and the other, which is of less resistance, is coupled up to the armature of the small demagnetising armature of R in series with the accumulators. This regulating armature is so connected that its E.M.F. opposes that of the accumulators. The high-resistance shunt circuit is of such proportions that, at the maximum speed at which it is intended to run the machines, it will give, without the aid of the regulating circuit, a magnetic field of sufficient intensity for the required E.M.F. in the generating armature. When thus driven, the second exciting circuit ought to have no current passing through it, a result which is brought about by the E.M.F. of the regulating armature being at its highest speed equal and opposite to that of the accumulators, which provide the current for exciting the magnets. If, however, the speed falls, the E.M.F. of the regulating armature is lessened in the same proportion, and being no longer equal

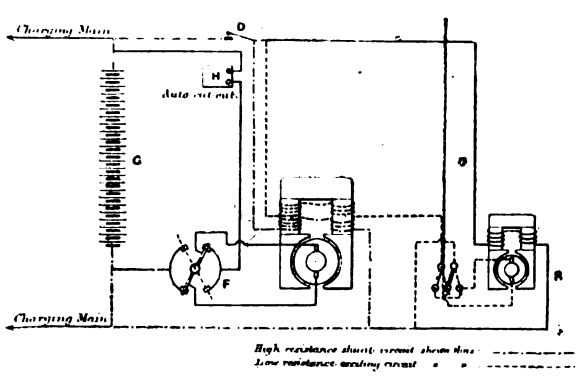

FIG. 9.—Sketch of Connections.

to the external pressure, permits a current to flow through the second or low-resistance exciting circuit of the magnets of Q, thus increasing the intensity of the magnetic field to make up for the reduction of speed. The result is that a practically uniform E.M.F. is maintained.

As will be seen from the diagram of connections, Fig. 9, the field of the small dynamo, R, is constant, as it is always united by the accumulators. All the automatic switching and reversing gears are controlled by the governor, M. The gear for altering the lead and reversing the polarity of the brushes of Q automatically when the axle commences to revolve in an opposite direction is shown in Fig. 10. The brushes, D (Fig. 8), are radial to the commutator, and are held in spring-holders, D^1, which are carried by bars, F^1, projecting from the brush arms, F F. These arms are mounted loosely on the inside pedestal, and they can be rocked automatically from one position to another, according to the direction of revolution of the shaft. The bars, F^1 F^1, are made to enter between one or other pair of contact jaws, S or S^1, which are connected respectively to the screw terminals, T T^1, for the circuit wires, so that as the polarity of the brushes is reversed on the reversal of the direction of rotation of the shaft, their connection with the circuit is at the same time reversed by the movement of the arms, F. The jaws, S S^1, on the right-hand side are coupled respectively with the jaws, S S^1, on the left-hand side by means of the copper bars, S^2. The brush arms and the contact bars, F^1 F^1, are

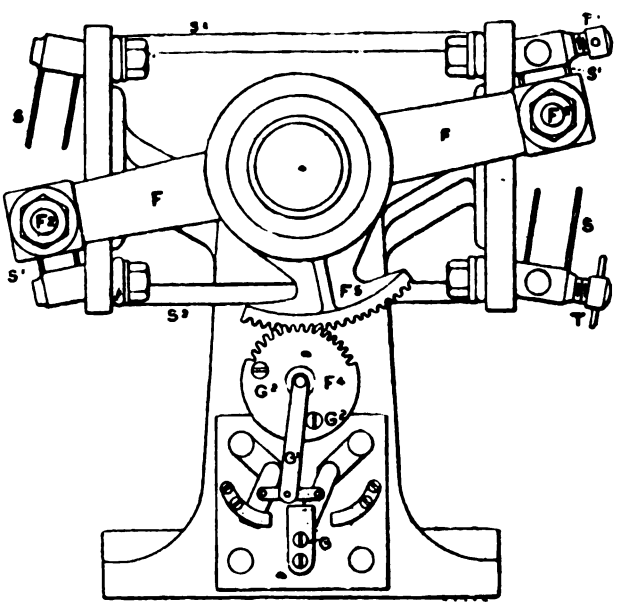

FIG. 10.—Reversing Gear.

moved over when the direction of rotation is changed by means of toothed gearing driven by the friction plates, N N^3. The plate N^3 is keyed to the shaft, but is free to be moved along so that the governor can draw it back as the speed increases.

The rotation of the brush arms at the same time reverse the connections from the demagnetising dynamo in the way shown at G, in Fig. 10. The next action of the governor is to close the shunt circuits of the two dynamos; finally, at a higher speed again, the main switch, which is of the quick-break type, is closed. The inverse operations

Digitized by Google

take place as the speed decreases, so that the main current is always broken before the shunt is disconnected. The weight of the dynamo, with bedplate, is 15cwt., and the weight of the countershafting, pulleys, etc., 13cwt.

Fig. 11 and 12, which represent a portion of a guard's van, will serve to illustrate the arrangement adopted on the Midland Railway. Upon the axle, A (Fig. 12), are keyed two driving pulleys, B B, which transmit the motion by link belting to a countershaft, C; from this, again, two short link belts are led to the dynamo, Fig. 11. Duplicate driving gear is employed to meet breakage or other mishap to the belting of either pulley. It will be observed that the distances between the centres are very short. It was the only way in which the dynamo could be arranged without displacing other gear, which could not be done.

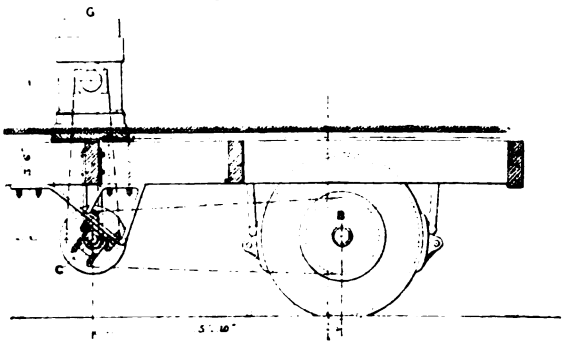

FIG. 11.—Sectional Elevation of Driving Gear.

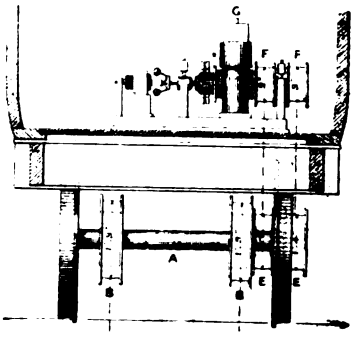

FIG. 12.—End Elevation of Driving Gear.

They may be conveniently arranged in boxes level with the footboards.

In arranging the accumulators in the train it is desirable, in order to meet the concussions due to shunting, etc., that the plates forming the cell shall be longitudinal to the train. In order to compensate for the increased pressure when the dynamo is in circuit, each vehicle is provided with an automatic relay which, when the voltage rises above what is required for the lamps, throws a sufficient resistance (usually 0·25 ohm) into the circuit.

With the object of distributing the current equally throughout the several parallels in the train, a small permanent resistance (0·25 ohm) is placed in each battery circuit. The output of the machine is scarcely affected by this arrangement, which, besides ensuring that each set of batteries or lamps receives its proper share of current, prevents an excessive current passing from a highly-charged set of accumulators into a set in an exhausted condition.

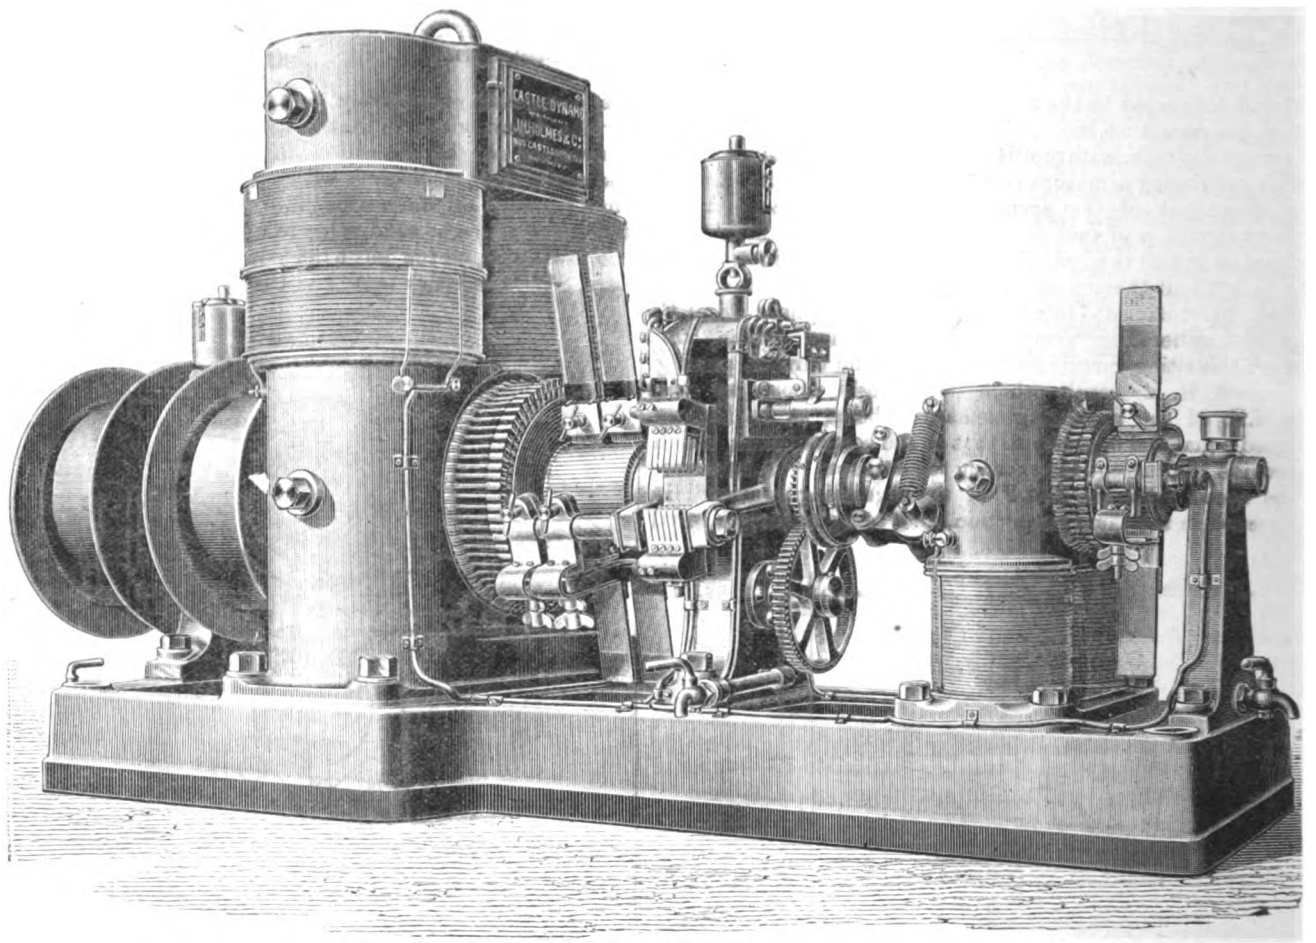

FIG. 13.

The accumulators employed were of the E.P.S. type, constructed and supplied by the Electrical Construction Corporation. With uncoupled trains the practice on the Midland was to place the dynamo in the guard's department and the cells in an adjoining one. The train is thus deprived of one compartment only—viz., that devoted to the cells. With main-line trains, where each vehicle carries its own batteries, the accumulators are of a smaller type—viz., C 15 for the Pullman cars and seven-compartment carriages, and C 11 for the smaller coaches. In all cases the electrical pressure is 35 volts, so that 18 cells are necessary for each

The important parts having been dealt with severally, the arrangement of the whole may now be described. Fig. 13 gives the view of the generating set. Fig. 14 represents a guard's van with dynamo and two coaches. From the two poles of the dynamo proceed the main cables, P and N, which are continued, by means of the couplings between each coach, throughout the train.

Digitized by Google

Similarly, a third main, L—the lamp main—is carried from the switch, S, in the guard's van throughout the train. The switch, S, provides a means by which the lighting main, L, may be connected to the positive main, P. Between the charging mains, P and N, are arranged the accumulators, C C′ C″, and between the negative pole and the negative charging wire is placed the automatic relay, G, the coils of which form the permanent resistance of 0·25 ohm already referred to. The same wire which joins this relay

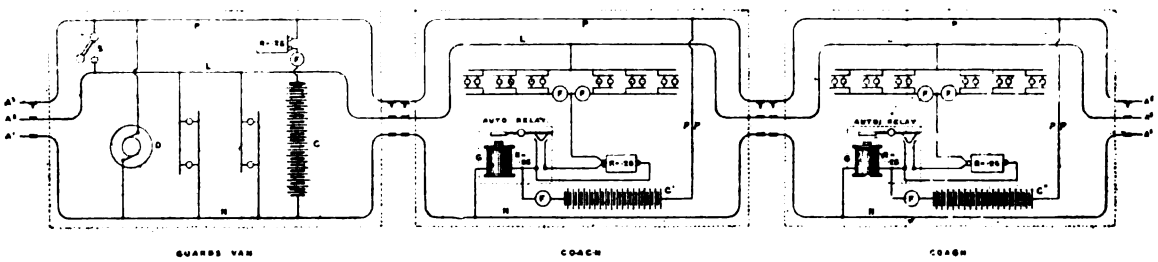

FIG. 14.—Method of Wiring the Carriages on the Midland Railway.

to the batteries makes connection with the lamp circuit, the opposite pole of which is joined to the lamp main. Safety fuses are arranged as shown at F.

ELECTRICAL COUPLING.

The difficulty of providing an efficient coupling is a matter of great importance. With trains which are not broken the details are simple, but where the marshalling of carriages has to be smartly dealt with at terminal or intermediate stations, it is essential that the coupling should not only provide for a good electrical connection, but also that it should admit of easy handling without the possibility of a mistake.

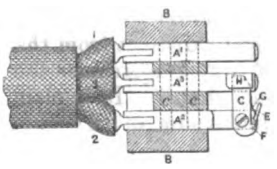

FIG. 15.

Fig. 15 is a sectional side elevation and Fig. 16 is a perspective view of one-half of a coupling enclosed in its iron case, and in the position which it occupies when coupled up for use. Each portion of the coupling is composed of three forked-shaped bars, Fig. 17, the projections, $a\ b$ and $a^1\ b^1$, which are split for the purpose of securing elasticity, interlocking the one with the other, and forming a reliable electrical contact between the opposite halves, A and A^1. Three of these bars are coupled together by insulating pins passing through the holes, c, and are then inserted in a block of ebonite, B. To the several bars, $A^1 A^2 A^3$ (Fig. 15), the main

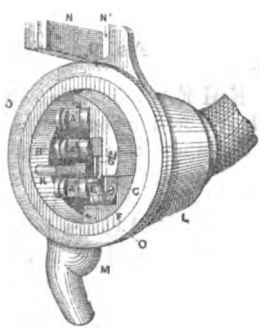

FIG 16.

cables are connected. A^1 and A^2 are joined to the cables forming the poles of the batteries, and A^3 to that forming the lamp circuit. A^2 has attached to it a movable connecting bar, C, which serves to join A^2 and A^3 when required, and thus complete the lighting circuit. C is provided with a trigger-piece, E, pivoted at F, free to be pressed inwards toward C, but otherwise retained in the position represented by means of the spring, G. Beyond its fulcrum, F, this trigger-piece is provided with a shoulder, which limits its movement away from C beyond the position desired. In Fig. 16 is shown a hooked rigid bar, K, the object of which is to operate the connecting-piece, C. K passes over the trigger, E, and forces back the connecting bar, C, until it rests in the shoe H attached to the bar A^2. On the two halves of the coupling being drawn apart, K engages with E, and thus draws the bar C over the shoe H in connection with A^2 to the shoe H^1 in connection with A^3. In this way, when the two halves of the coupling are pressed together, the cross-connection, C, is broken, and the three bars, A^1 A^2 A^3, are placed in contact, thus establishing the communication of the several cables.

The position of K in relation to C, when the coupling is closed, is that represented in Fig. 18. The hook, K, is not in electrical connection with either of the bars, but is fixed to the block of ebonite in which they are bedded. For slip-coaches, a special flat bar, not provided with a hook, is employed, the object being that the contact-piece, C, may be thrust back, but not again drawn over into the contact position when the coupling is pulled apart.

Fig. 16 shows the general arrangement of the whole, which is similar to that of the automatic brake coupling. M is the hook at its lower part, and N the straight bar, with a slot, N^1, so arranged that the bar, N, of the one

FIG. 17.

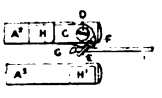

FIG. 18.

half-coupling shall enter the slot, N^1, of the other half-coupling, and the hook, M, of the one engage with the corresponding part of the other. O is an indiarubber ring fixed in an undercut groove formed in the flange of the metal case, L, serving to exclude the wet. The weight of the two, when hooked together and left suspended

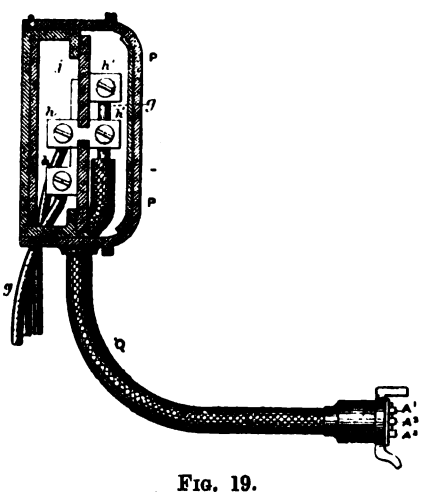

FIG. 19.

between the vehicles which they connect, draws them firmly together at the upper part.

Fig. 19 represents in sectional side elevation the half-coupling joined to the connecting-box, P, fixed on each end of the vehicle. The three cables, g, from the vehicle are brought up and attached to terminals, h, fixed to an insulating disc, J. To a continuation, h^1, of these terminals are attached the three leads, g^1, comprised within the combined cable, Q, and which are at their other ends attached to the bars, A^1 A^2 A^3.

Digitized by Google

At a convenient point at each end of the vehicle is also placed a dummy coupling, which, as is implied by the name, is not electrically connected. It is composed of a block of wood, to which is fixed the hook, K, and is intended to provide a position of rest for the coupling when the train is broken up, and to act as an automatic switch. On the coupling being placed upon it, the connecting-piece, C (Fig. 15), is thrust back by means of the hook, K, and the lights are thereby turned out. If they are required to be kept on, it is only necessary to allow the coupling to hang down instead of placing it upon the dummy.

Remarks on the Midland System.

The reasons which led to the abandonment of the electric lighting of the trains on the Midland Railway to lines can only be conjectured by outsiders. The opposition of gas lighting was likely to be the most weighty of these. The light supplied electrically under Mr. Langdon's supervision was good and well maintained. The exigencies of the main-line traffic were exceedingly hard on the accumulators employed. Of course, a sufficient number of carriages has to be equipped to run the busiest portion of the year when long trains are required. The trains were repeatedly broken up, and it frequently occurred that the accumulators in some individual carriage enjoyed but for a short time the fostering care of the dynamo. The carriage would after that be left in a siding for perhaps two or three weeks and then suddenly be used again. As a result, the accumulators suffered, and the dynamos had to give an excessive current while keeping up the normal pressure of the lamps. The dynamo part was, I understand, perfectly successful, and maintained a good constant pressure independently of the speed. Then, after a time, the question of uniformity of lighting had to be considered, and the directors decided that the smaller competitor should go to the wall. I have been unable to ascertain recent figures as to the cost of maintenance, and shall refer to Mr. Langdon's paper again for the figures he published in 1891. The paper read by him before the Institution of Civil Engineers has been of great service to me while working up information on train lighting.

THE THEORY OF ALTERNATING CURRENTS.—V.

BY A.INST.E.E.

§ 14. **Circuits with Induction and Resistance in Series—Reactance.**—The importance attached to the presence of self-induction in a circuit has already been mentioned, and in this paper we propose to collect the various factors which have been considered separately, and which are connected very intimately in alternating-current circuits, and explain how to deal with the quantitative relationships between them. From § 1-§ 5 we know that

(1) L, the coefficient of self-induction in absolute units, represents the number of lines of force linked with the circuit due to a change in the current strength at the rate of one absolute unit per second.

(2) If L be given in henrys (practical units), its magnitude is 10^9 times the absolute unit.

(3) If a continuous current changes at the rate of C amperes per second, the inductance is L C henrys, and the counter E.M.F. or E.M.F. of self-induction, E_s, is L C volts.

(4) $L = 4\pi n^2 A/10^9 l = 4\pi^2 n^2 r^2/10^9 l = 4\pi^2 n^2 r^2 \mu/10^9 l$;

where n = number of turns in coil, r = radius of coil,
A = area of coil = πr^2;
l = length of coil in centimetres, and μ = permeability of core.

It is therefore evident that in an alternating-current circuit, containing a coil of inductance L, and in which a current of C virtual amperes with a frequency of $\frown\!\!\smile$ cycles per second is passing, the counter E.M.F. is $2\pi \frown\!\!\smile$ L C virtual volts. Since 2π is the number of radians corresponding with each cycle, therefore $2\pi \frown\!\!\smile$ is the angular velocity of the armature This counter E.M.F. is a function of the current traversing the circuit, and, as we shall see presently, it is one of the components of the impressed E.M.F. It is the existence of this counter E.M.F. that makes Ohm's law, as stated for direct currents, inapplicable for alternating-current circuits, since it reacts on the impressed E.M.F., and for this reason it is termed the *reactive E.M.F.*—that is, the *reactive E.M.F.* $= 2\pi \frown\!\!\smile$ L C virtual volts, or, in words,

Reactive E.M.F. = 2 π × frequency × henrys × amperes;
= angular velocity × henrys × amperes.

It will also be noticed that the equation $(2\pi \frown\!\!\smile \text{L}) \times \text{C}$ = reactive E.M.F. is of the same form as R × C = E, from which it follows that $2\pi \frown\!\!\smile$ L is a quantity equivalent to resistance, and for this reason it is measured in ohms. To this quantity—$2\pi \frown\!\!\smile$ L, or ω L, where ω is the angular velocity—the name *reactance* has been given by the American Institute of Electrical Engineers, at the suggestion of Messrs. Steinmetz and Bedell, and is meeting with general acceptance. When we remember that the reactive E.M.F. is an induced pressure, and obeys the general laws of induced currents, it is easy to see that its maximum value occurs at the moment when the value of C is zero. For when C is a maximum the number of lines of force passing through the coil is a maximum, and they are at right angles to the plane of the coils, and as at this moment this corresponds to the position of the revolving coil (armature) of our ideal alternator, § 7, when in the vertical position, the rate of change in the linkages is a minimum, and the induced E.M.F. or reactive E.M.F. is zero. When, however, C is zero (and this occurs when the revolving coil of the ideal alternator is at right angles to the vertical position), the rate of change in the number of linkages in the coil is a maximum, so that in all cases the reactive E.M.F. follows the current, producing the inductance at right angles. If these results be represented graphically, the reactive E.M.F. must be plotted in a direction at right angles to the current, of which it is a function. Thus we see that the reactive E.M.F., in overcoming the resistance of the coil, absorbs no power for it acts at right angles to the current, and is quite distinct from that component of the impressed E.M.F. which overcomes the ordinary resistance of the rest of the circuit. It is plain, then, that the impressed E.M.F. is the sum of two component E.M.F.'s, but since their directions are not coincident—one being in quadrature with the other—the geometrical and not the arithmetical sum is taken. This is shown graphically as follows, the problem being a simple exercise in compounding two forces at right angles to one another:

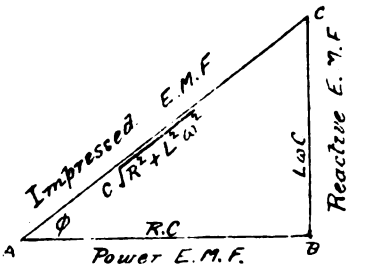

Fig. 9.

In Fig. 9 the E.M.F. overcoming the resistance of the circuit is denoted by the horizontal line A B, and is termed the power E.M.F., since this resistance consumes power, and the other component, the reactive E.M.F., is denoted by B C at right angles to A B. To compound these two forces the extremities A and C are joined by the line A C, which denotes the impressed E.M.F. in magnitude and direction. Hence

Impressed E.M.F.

$$= \sqrt{(\text{power E.M.F.})^2 + (\text{reactive E.M.F.})^2} \quad (1)$$

This expressed in symbols is

$$E^2 = (R\,C)^2 + (L\,\omega\,C)^2 = C^2\,[R^2 + L^2\,\omega^2],$$

$$\therefore E = C\sqrt{R^2 + L^2\omega^2} \quad . \quad . \quad . \quad . \quad (2)$$

where $\omega = 2\pi \frown\!\!\smile$, or $2\pi/T$, T being the periodic time of a cycle.

From (2) we get the value of the current, thus

$$C = \frac{E}{\sqrt{R^2 + L^2\,\omega^2}} \quad . \quad . \quad . \quad . \quad . \quad (3)$$

Digitized by Google

This is the general form of the equation, corresponding to Ohm's law, and may, in fact, be called Ohm's law for alternating currents. In such cases C and E are virtual amperes and virtual volts respectively.

§ 15. **Angle of Lag.**—It will be noticed from the above figure that the power E.M.F. makes an angle ϕ with the impressed E.M.F., and since the current flowing through the circuit coincides in direction with the power E.M.F., it is evident that the current *lags behind* the impressed E.M.F., and the angle B A C, or ϕ, is termed the *angle of lag*. The tangent of this angle, or tan ϕ, measures the *retardation of phase*, and it may be mentioned here that ϕ can never exceed 90deg. From Fig. 9 we see that

$$\tan\phi = \frac{L\omega}{R} = \omega\frac{L}{R} = \omega \times \text{time constant (see § 6)},$$

an expression which emphasises the facts mentioned in § 6.

By noting that $C = \frac{E}{R}$, when self-induction is absent in a circuit, it is obvious that the effects of self-induction are twofold—*i.e.*, (1) a retardation of phase in the undulations of the current, and (2) the current strength is diminished in the ratio of R to $\sqrt{R^2 + L^2\omega^2}$—that is, as if the resistance had increased in the ratio of $\sqrt{R^2 + L^2\omega^2}$ to R.

It should be noticed that ω—angular velocity—depends upon the speed, and, in consequence, self-induction is a more important factor than the resistance at high speeds. This is clear from the following simple exercise. A circuit has a resistance of 50 ohms and an inductance of 0·5 henry, then if the frequency is 100, $\sqrt{R^2+L^2\omega^2} = \sqrt{(50)^2 + (2\pi \times 100 \times \cdot 5)^2} = 316\cdot5 = 6 \times R$.

Maxwell has expressed the fact that a retardation of phase is due to self-induction in circuits through which periodic current flow, by writing the instantaneous value of the current as follows:

$$C = \frac{D \sin(\theta - \phi)}{\sqrt{R^2 + L^2\omega^2}} \quad \ldots \quad (4)$$

which expresses *Maxwell's law* algebraically. θ is the angle through which the armature of the alternator has turned from its vertical position in the time under consideration, and ϕ is the angle of lag due to self-inductance, whilst $\sqrt{R^2 + L^2\omega^2}$ indicates the cause of the diminution of the current strength. For practical purposes, however, the form given in equation (3) § 14 is the most convenient, since the ammeter and voltmeter gives the actual values of C and E.

§ 16. **Impedance.**—The denominator—$\sqrt{R^2+L^2\omega^2}$—in equations (3) and (4) is a quantity which in Ohm's law for alternating currents takes the place of the resistance of the circuit, and is measured in ohms. It has been termed "virtual resistance," in conjunction with the terms "virtual volts" and "virtual amperes"; but its generally accepted name is *impedance*, a term which was first introduced by Mr. Oliver Heaviside, and finally adopted by the British Association Committee on Electrical Standards at the Newcastle meeting, 1889, in preference to the term *résistance apparante* adopted at the Paris Congress the same year. The above committee define *impedance as the ratio of the effective E.M.F. to the effective current.* Considered by itself, impedance is the sum of every form of obstruction—such as dissipative resistance, reactance, and condensation (which will be considered in our next)—met with in alternating-current circuits. Seeing that impedance is measured in ohms, it is not advisable to term dissipative resistance ohmic resistance, as is frequently done. Since impedance is the square root of the sum of two squares, or

$$(\text{Impedance})^2 = (\text{resistance})^2 + (\text{reactance})^2,$$

impedance may be graphically represented by the hypotenuse of a right-angled triangle, as in Fig. 10, in which the sides A B and B C = R and L ω respectively. In the triangle A B C, Fig. 9, giving the E.M.F.'s, it will be noticed that C is a common factor in each expression, so that Fig. 10 is the previous figure modified, and is useful in determining impedance and angle of lag from the quantities R, L, and ω. The method of applying the above principles in practice is shown in the following solution of an example given at the City and Guilds Institute examination in 1892.

Example.—If with 120 alternating volts having a frequency of 70 periods per second, there is produced in a circuit of four ohms an alternating current of 24 amperes, what is the coefficient of self-induction, and the angle of lag of the current?

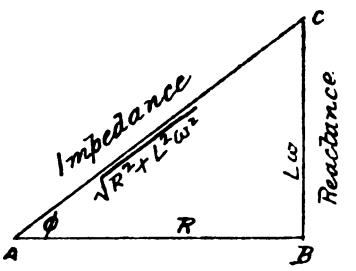

Fig. 10.

(1) Determination of L, the coefficient of self-induction. Substituting the given values in the equation,

$$C = \frac{E}{\sqrt{R^2 + L^2\omega^2}},$$

we get

$$24 \text{ amperes} = \frac{120 \text{ volts}}{\sqrt{(4)^2 + (2 \times \frac{22}{7} \times 70 \times L)^2}} = \frac{120}{\sqrt{16 + (440L)^2}}.$$

$$\therefore \sqrt{16 + (440\,L)^2} = \frac{120}{24} = 5,$$

or, $$(440\,L)^2 = 25 - 16 = 9.$$

$$\therefore 440\,L = 3,$$

and $$L = \frac{3}{440} = 0{\cdot}00682 \text{ henry}.$$

(2) Determination of ϕ, the angle of lag.

$$\text{Since } \tan\phi = \frac{L\omega}{R} = \frac{2.\pi \frown L}{R} = 2 \times \frac{22}{7} \times 70 \times \frac{3}{440} \times \tfrac{1}{4}$$
$$= \cdot 75;$$

$\therefore \phi = 36°\ 52'$ or 37° (approx.) from tables of tangents.

§ 17. **Curves Showing Lag.**—It is very interesting and instructive to show the retardation of phase due to inductance in a circuit by means of a set of curves as in Fig. 11.

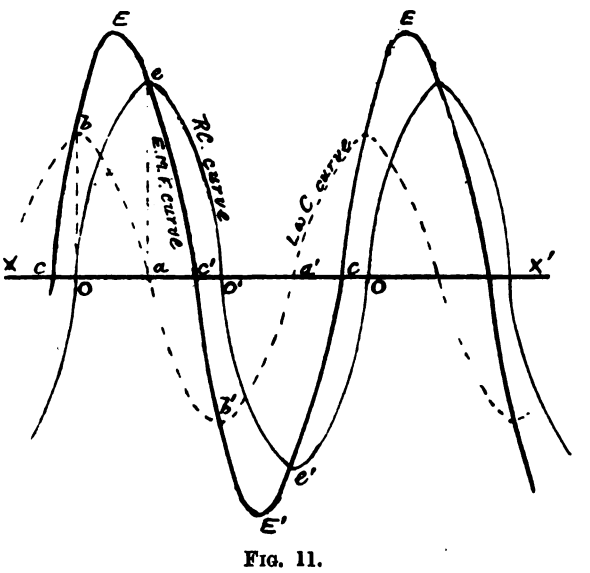

Fig. 11.

To further make the example instructive, we shall represent graphically the example just considered numerically. If the self-induction were absent, then the pressure required to drive 24 amperes through the four ohms resistance is found as follows: E = C × R = 24 × 4 = 96 volts = power E.M.F. In the figure the curve O e O' e' O represents this

Digitized by Google

E.M.F., and is drawn to scale, the ordinate $a\,e$ denoting 96. Since inductance is present, the E.M.F. of self-induction is $L\,\omega\,C = 2 \times \frac{22}{7} \times 70 \times \frac{3}{440} \times 24 = 72$ volts, and as this reactive E.M.F. is in quadrature with the power E.M.F. its maximum value occurs when the power E.M.F. is zero, and the ordinate O b is drawn to the same scale as before, from O equal to 72, and the curve $b\,a\,b'\,a'$ represents the pressure overcoming the reactance. To get the impressed E.M.F. curve, the ordinates of the two curves—the power E.M.F. curve and the reactive E.M.F. curve—for the same points on the line $x\,x'$ are added, and we get the curve $c\,E\,c'\,E'\,c$, and the set of curves thus drawn depict the facts in the preceding paragraphs.

RESONANCE IN TRANSFORMER CIRCUITS.*

BY FREDERICK BEDELL AND ALBERT C. CREHORE.

The reactive action of a condenser in an alternating-current circuit produces effects of theoretical interest and practical importance. The resultant observed phenomena under different conditions of operation are many and various; but under whatever particular sets of conditions the condenser is used the effects produced are closely correlated, and may be grouped together in one class. Electrical resonance is one of the striking phenomena of this class. In a single circuit resonance is obtained when, inductance and capacity being present, the resultant reactance is zero—that is, the reactance of the condenser is exactly equal and opposite to the reactance due to self-induction. The natural period of the circuit then equals the period of the impressed E.M.F. Complete resonance is thus obtained only when the impressed E.M.F. varies harmonically.

Effects corresponding to resonance in a single circuit may be produced by the reactive influence of one circuit upon another, occasioned by the mutual induction of the two circuits. Such effects have been discussed by Dr. M. I. Pupin, who treats the case of a transformer containing a condenser in the secondary circuit; to this class of phenomena he gives the name "electrical consonance." Additional discussion of the same subject has been given by Mr. C. P. Steinmetz.

Resonance, in this case, occurs when the relation between the primary and secondary is such that the apparent reactance of the primary circuit is zero. The elastic influence of the condenser is transferred from one circuit to the other on account of their mutual relationship, and the natural period of the primary circuit depends not only upon the value of its own constants, but upon those of the secondary as well. There is a surging of energy back and forth between the primary circuit and the secondary condenser, by intervention of their common magnetic field: the period of these surgings determines the period of the system. A condenser in either primary or secondary circuit may give rise to such oscillations.

In the general sense of resonance, the case here described would be a particular case, but for distinction we may apply the term "simple resonance" to the phenomena observed in a single circuit, the term "consonance," suggested by Dr. Pupin, being used when the resonant action is transferred from one circuit to another by the mutually inductive influence between them.

The conditions necessary for consonance, although not so simple as those for simple resonance, are definite, and may be readily determined. These are in part discussed in the papers already referred to. We have had occasion to investigate the action of condensers with transformers, and to develop their general theory, interpreting the results both analytically and graphically. The application of this general treatment to the case of resonance or consonance throws light upon the nature of the phenomena, and brings out certain important relations. With these results many of the conclusions of Dr. Pupin agree, but not so some of his deductions, particularly the statement of the conditions under which consonance occurs—namely, when the apparent impedance of the primary circuit is either a maximum or a minimum. To make our discussion complete, we may be pardoned, therefore, if we touch upon some ground in part covered before.

Problems of this nature are usually capable of two essentially different modes of treatment, leading to identical results: first, the general analytical treatment; second, the synthetical graphical treatment. Which to use is a matter of preference. It is a choice of which way to go around a block; one way or the other may be shorter, but the same point is reached by either route. These methods are well illustrated in the present instance. In the study of resonance and consonance the graphical method is the more direct. It is replete with obvious conclusions, and at once brings out relations not simply shown by analytics.

After a brief analytical treatment we will pass to the graphical.

Analytical Treatment.

Let us use the following notation:

I_1 = primary current.
R_1 = resistance of the primary circuit.
L_1 = self-induction of the primary circuit.
C_1 = capacity of the primary circuit.
K_1 = reactance of the primary circuit.
J_1 = impedance of the primary circuit.

Let I_2, R_2, L_2, C_2, K_2, and J_2 represent the corresponding quantities for the secondary circuit, within and without the transformer.

E = harmonic E.M.F. supplied to the primary circuit.
ϕ = angle of phase difference between primary E.M.F. and current.
M = coefficient of mutual induction between the primary and secondary circuits.
$\omega = 2\pi \times$ frequency.

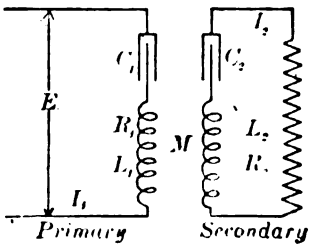

FIG. 1.—Arrangements of Circuits.

Let R_1', L_1', K_1', and J_1' represent the apparent values of the quantities indicated.

It is to be noted that

$$\text{reactance} = K = \omega L - \frac{1}{C\,\omega};$$

$$\text{impedance} = J = \sqrt{R^2 + K^2};$$

$$\text{apparent impedance} = J_1' = \sqrt{R_1'^2 + K_1'^2}.$$

on account of which OB would be little more than 90deg. behind OA.

The vector sum of the active E.M.F., OH, and the reactive E.M.F., HT, determines OT, the E.M.F. to overcome the impedance proper of the primary. The impressed E.M.F., OF, is the sum of OT, and the back E.M.F., TF.

Under the assumption that I_1 is constant, evidently OB is constant. As the secondary capacity or reactance is varied, the point D moves on the circle ODB, and the point F moves similarly on the circle TQFPG. This determines the phase of the primary E.M.F., OF, which may be either in advance of the current or behind it, being in phase with it at two points, P and Q. In the case represented in the figure, the E.M.F. is behind the current.

The line, TF, showing the back E.M.F. due to the secondary current, may be resolved into

$$\text{the active E.M.F. } TW = TF \cos\theta_2 = \left(\frac{M\,\omega}{J_2}\right)^2 R_2\,I_1;$$

$$\text{the reactive E.M.F. } WF = TF \sin\theta_2 = \left(\frac{M\,\omega}{J_2}\right)^2 K_2\,I_1.$$

These are the components of the back E.M.F. Adding these to OH and to HT respectively, we obtain the total values of the active and reactive E.M.F. in the primary—viz.:

$$OZ = R_1 I_1 + \gamma^2 R_2 I_1 = R_1' I_1;$$
$$ZF = K_1 I_1 - \gamma^2 K_2 I_1 = K_1' I_1.$$

* From the *Physical Review*, New York.

Digitized by Google

The diameter of this primary circle is the value of TF, when in the position TG, which occurs when K = 0. The secondary current is then in the direction of OB, and we have $I_2 = M\omega I_1 \div R_2$. The diameter of the primary circle is then

$$M\omega I_2 = M\omega \frac{M\omega I_1}{R_2}.$$

A primary condenser changes the length of HT, the point T moving towards H, as the condenser reactance is increased; in fact, it may be moved to the right of H. For a case in which the primary reactance is due to inductance alone, the diagram as drawn applies.

With the secondary condenser removed, the point F would move to some point as Y, and the point D to a corresponding point, Y', depending upon the resistance in the secondary circuit, and upon the amount of magnetic leakage, a small amount of which is here assumed present. The limiting positions therefore of the point F are Y and T. As TY would be the position of TF in the absence of the secondary condenser, it follows that a line drawn from Y to F in any position shows the component of the primary E.M.F. due to the secondary condenser. The point F could not lie on the dotted portion of the curve.

If we divide the E.M.F. diagram, Fig. 2, by the value of the primary current for which it was constructed, we obtain (Fig. 3) an impedance diagram, independent of current or E.M.F. Here OH represents ohmic resistance [or a power coefficient where other losses are involved]; HT is the primary reactance; OT is the primary impedance. The apparent primary impedance, OF, is the sum of the impedance OT and of TF, an impedance component due to the reaction of the secondary; of this, YF is due to the presence of the secondary condenser.

From Fig. 3 we have

$$OZ = R_1' = R_1 + \gamma^2 R_2;$$
$$ZF = K_1' = K_1 - \gamma^2 K_2;$$
$$OF = J_1' = \sqrt{R_1'^2 + K_1'^2}.$$

For the case in which the secondary alone contains a condenser,

$$\frac{1}{C_1\omega} = 0 \text{ and } K_1 = L_1\omega.$$

For the general case, in which we suppose that condensers with capacities C_1 and C_2 are located in the primary and secondary circuit respectively, as shown in Fig. 1, we have the solution for the primary current—

$$i_1 = I_1 \sin(\omega t + \phi),$$

where
$$I_1 = \frac{E J_2}{\sqrt{a^2 + b^2}},$$

and
$$\phi = -\arctan\frac{b}{a} + \arctan\frac{K_2}{R_2},$$

$$\tan\phi = \frac{-\frac{b}{a} + \frac{K_2}{R_2}}{1 + \frac{b}{a}\cdot\frac{K_2}{R_2}} = -\frac{b R_2 - a K_2}{a R_2 + b K_2}.$$

Here a and b are abbreviations which, in this general case, have the values—

$$a = -\omega^2 (L_1 L_2 - M^2) + \left(\frac{L_1}{C_2} + \frac{L_2}{C_1} + R_1 R_2\right) - \frac{1}{C_1 C_2 \omega^2},$$

$$b = \omega (R_1 L_2 + R_2 L_1) - \left(\frac{R_1}{C_2\omega} + \frac{R_2}{C_1\omega}\right);$$

or, $a = R_1 R_2 - K_1 K_2 + M^2\omega^2$,

$b = R_1 K_2 + R_2 K_1$.

Substituting these values of a and b, we obtain

$$\tan\phi = -\frac{R_2^2 K_1 + K_1 K_2^2 - M^2\omega^2 K^2}{R_1 R_2^2 + R_1 K_2^2 + M^2\omega^2 R}.$$

By rearrangement we obtain our results in the following useful form:

$$\tan\phi = -\frac{K_1 - \gamma^2 K_2}{R_1 + \gamma^2 R_2} = -\frac{K_1'}{R_1'};$$

and
$$I_1 = \frac{E}{\sqrt{(R_1 + \gamma^2 R_2)^2 + (K_1 - \gamma^2 K_2)^2}} = \frac{E}{J_1};$$

where
$$\gamma = \frac{M\omega}{J_2} = \frac{I_2}{I_1}.$$

We thus have for the primary circuit—

apparent resistance $= R_1' = R_1 + \gamma^2 R_2$;
apparent reactance $= K_1' = K_1 - \gamma^2 K_2$;
apparent impedance $= J_1' = \sqrt{R_1'^2 + K_1'^2}$.

The apparent primary reactance equals the real reactance diminished by a multiple of the secondary reactance. The apparent primary resistance equals the real resistance increased by the same multiple of the secondary resistance. This multiple is the square of the ratio of secondary and primary currents.

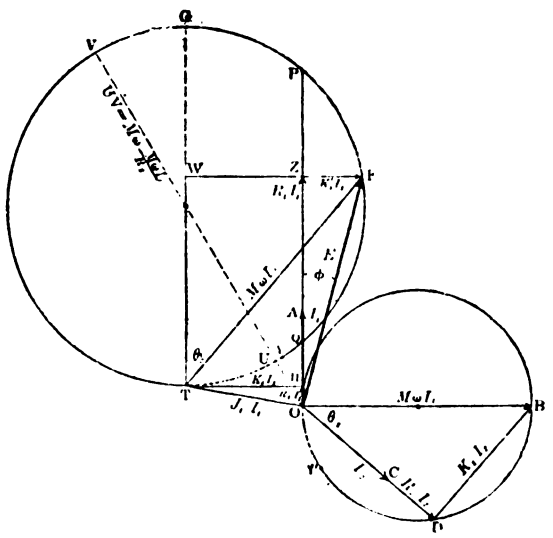

FIG. 2.—Impedance Diagram. Positive Rotation is Counter-clockwise

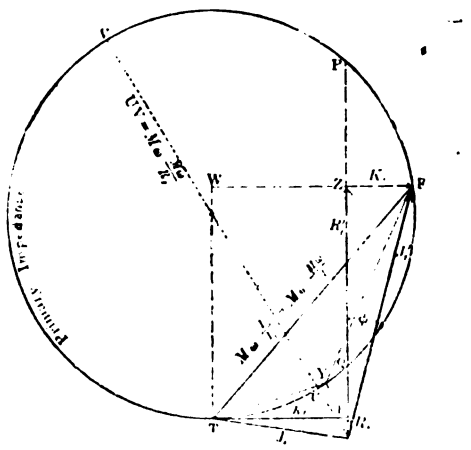
For completeness we may add

$$i_2 = I_2 \sin(\omega t - \phi - 90\text{deg.} - \theta_2),$$

where
$$I_2 = \frac{M\omega I_1}{J_2},$$

and
$$\tan\theta_2 = \frac{K_2}{R_2}.$$

These results are independent of any assumption concerning magnetic leakage. They are rigorously correct when the capacities and coefficients of induction are constant, and the impressed E.M.F. is harmonic. Where the E.M.F. is not harmonic, the solution may be applied to each component of the complex wave; or we may make use of the idea of an equivalent sine wave, which, although useful, and in many cases capable of giving approximately correct results, is not rigorous for this case.



3. Impedance Diagram (obtained by dividing E.M.F. Diagram, Fig. 2, by I

The conditions for consonance are readily obtained by noting the conditions under which the apparent reactance of the primary is zero. These will be discussed after the graphical treatment of the problem, from which these results analytically obtained are independently derived from geometrical considerations.

GRAPHICAL TREATMENT.

In the graphical treatment of resonant phenomena, or of any alternating-current problem, there are four correlated

Digitized by Google

methods of representation. We may plot E.M.F.'s, as in Fig. 2; impedances, as in Fig. 3, obtained by dividing our E.M.F. diagram by current; admittances, as in Fig. 4, the reciprocal of our impedance diagram; and currents, as in Fig. 5, obtained by multiplying the admittance diagram by an E.M.F. Figs. 4 and 5 are reciprocal to Figs. 2 and 3. There is a close relation between all of these diagrams. We will build up Fig. 2, step by step, and discuss it in detail; the full discussion of the other diagrams will scarcely be called for. Our particular study is to determine the action of the condenser in the secondary circuit.

In Fig. 2, let OA = I_1 represent the primary current, which for the present is assumed constant; OB = $M \omega I_1$, drawn 90deg. behind OA, represents the E.M.F. induced in the secondary by the primary current, the instantaneous value of this E.M.F. being $M \frac{di_1}{dt}$. Positive direction of rotation is taken as counter-clockwise.

The secondary current, OC, lags behind OB by an angle θ_2, whose tangent is $K_2 \div R_2$. The primary impressed E.M.F., E, is the sum of three components: OH = $R_1 I_1$, to overcome primary resistance; HT = $K_1 I_1$, to overcome the reactance of the primary circuit; and TF = $M \omega I_2$, to overcome the back E.M.F. induced in the primary by the secondary current. These components are in the direction of the primary current, and at right angles to the primary and secondary currents respectively. When iron is present, R_1 is strictly a power coefficient, hysteretic and ohmic; OH is the power E.M.F. for all expenditure of power excepting in the secondary. Eddy currents and hysteresis are thus taken into consideration, in so far as they occasion an expenditure of energy. Hysteresis would likewise cause a lagging of magnetisation behind the magnetising current.

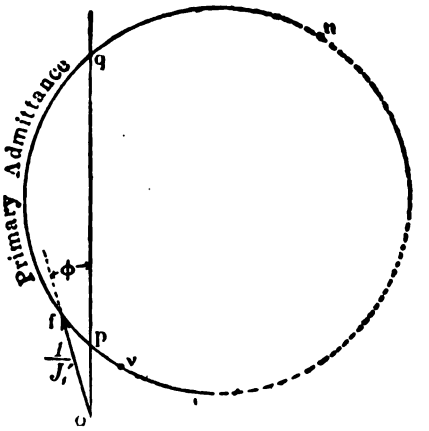


FIG —Admittance Diagram (the Reciprocal of the Impedance Diagram).

From Fig. 2 we also have

$$E = I_1 \sqrt{R_1'^2 + K_1'^2} = I_1 \sqrt{(R_1 + \gamma^2 R_2)^2 + (K_1 - \gamma^2 K_2)^2}.$$

We have thus obtained by geometrical methods the results derived above by analytical processes. In Fig. 3, for the maximum and minimum values of the apparent impedance, we have OV and OU; for consonance we have the values OQ and OP. We may note that while for consonance the secondary condenser decreases the apparent reactance of the primary to zero, it gives rise to a corresponding increase in the apparent resistance.

If, in Fig. 3, OF is a vector representing the apparent impedance of the primary, we may obtain the value of the admittance by taking the reciprocal of OF. Now OF is a vector drawn from the origin O, and lies on the circle TQFPG as the secondary reactance is changed. By the principle of reciprocal vectors it follows that, if the locus of the impedance vector is a circle, the locus of the admittance vector (its reciprocal) will likewise be a circle. In Fig. 4, *of* is a vector representing admittance, being always equal to the reciprocal of OF, Fig. 3. The circle *vpfqu* in Fig. 4 is reciprocal to the circle VPFQU in Fig. 3. We may note the reciprocal points *u*, *v*, *p*, *q*, and U, V, P, Q. The points of minimum and maximum impedance U and V correspond to the points of maximum and minimum admittance *u* and *v*. The admittance diagram is evidently independent of current or E.M.F.

Let us now assume an alternating E.M.F., **E, constant** in value, supplied to the primary circuit. **Multiplying** our admittance diagram (which for simplicity is **not complete**) by E, we obtain the current diagram, Fig. 5. **Here** *oh* is the power current in the direction of the **E.M.F.**; *ht* is the reactive current, and represents no work. **The resultant** is *ot*, the open-circuit current, which is denoted **by** I_0. It is to be observed that *oh* is the current representing **the power** expended in all ways other than in the **secondary** circuit. The actual current, I_1, which flows in the **primary** when the secondary is closed, is the resultant of the **open-circuit** current, *ot*, and the component, *tf*, due to the **reaction** of the secondary, which is equal to the **secondary current** multiplied by the ratio of secondary to **primary turns** ($S_2 \div S_1$).

As the secondary reactance is varied, the **primary current** changes in magnitude and direction **according to the** reaction of the secondary, as lies upon the circle, **as shown**, as a locus. The dotted portion of the circle **corresponds to** the dotted portion in the previous figures. **This diagram** corresponds to that of Mr. Steinmetz.

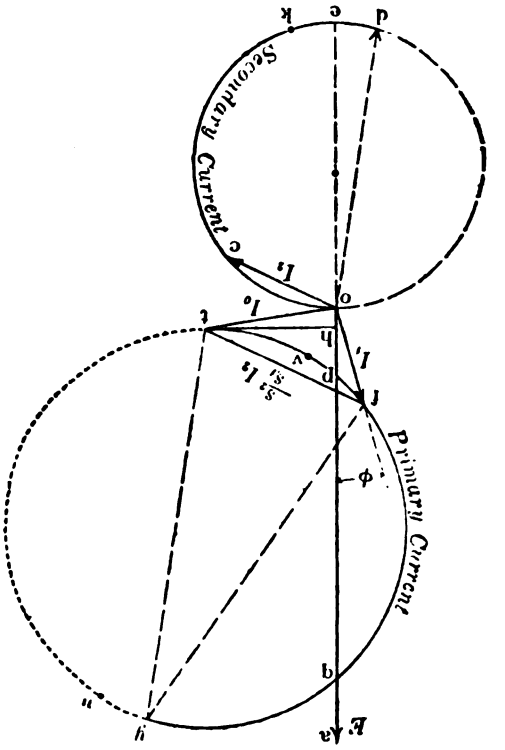

FIG. 5.—Current Diagram Admittance Diagram Multiplied by Primary E.M.F., E).

The points of consonance, *p* and *q*, correspond to P and Q above. If consonance can be obtained at all, there are two values of the primary current for which it may be obtained.

The secondary current, I_2, varies proportionally to *tf*, and is drawn as *oc*, with its locus on the circle *cked*. In the present case (which assumes a certain amount of magnetic leakage), the secondary current would take the position *od*, if the secondary condenser were removed from the circuit. It could only move on to the dotted part of the curve in case self-induction were added to the secondary circuit, or, what is the same thing, the magnetic leak increased. We thus see the action of the condenser and of magnetic leak are opposed, and that magnetic leak may be thus compensated for. In fact, the secondary circuit may be given a capacity which will over-compensate for magnetic leakage; as a constant-potential transformer is loaded the secondary E.M.F. may rise, despite the magnetic leakage drop and the fall in potential due to ohmic resistance. In the absence of condenser, magnetic leak, and open-circuit losses—that is, if *oh* were zero—the secondary current would be in the direction *oe*. Losses on open circuit, eddy currents, hysteresis, etc., give to the open-circuit current the power component *oh*, and in the absence of magnetic leak the secondary current would assume the position *ok*.

In the present instance the point of minimum impedance,

Digitized by Google

U, and maximum current, u, are on the dotted portion of their respective circles, and so could not be actually obtained. This, however, is not necessarily so. By the principle of reciprocal points it follows that the product of the maximum and minimum currents is equal to the product of the two consonant values of current—that is,

$$ou \times ov = op \times oq.$$

We may best examine the conditions of consonance by returning to Fig. 2. When the primary circle does not intersect OP there can be no consonance. Analytically we would obtain imaginary values. If there is one condition for consonance there must be two, corresponding to the points P and Q, except in the limiting case, when the circle is tangent to OP. Then HT would equal the radius of the circle, and

$$K_1 I_1 = \frac{M \omega}{2} \frac{M \omega I_1}{R_2}.$$

For consonance to be possible, we must therefore have the relation

$$M^2 \omega^2 > 2 K_1 R_2.$$

The points of consonance are determined by equating the value of primary apparent reactance to zero ; thus

$$K_1' = K_1 - \gamma^2 K_2 = 0 ;$$

or

$$\frac{K_1}{K_2} = \frac{M^2 \omega^2}{R_2^2 + K_2^2}.$$

Two values of K_2 will satisfy this condition. Frequency is an important factor in this criterion. The conditions for consonance are obtained when OD is perpendicular to TQ or to TP.

A particular case, which may be termed "pure consonance," is obtained when the natural period of each circuit independently is equal to the period of the impressed E.M.F. The period of the system in this case is evidently the same as the period of either circuit. We have K_1 and K_2 each equal to zero. The point T coincides with H, and OD takes the position OB.

We have seen that all our conclusions concerning consonance may be obtained independently by analytical or by graphical methods, the results by the two methods being easily identified. The graphical method, however, appeals to us as the more evident.

Although it is readily shown that the loci of primary impedance and admittance are circles, as the secondary reactance is changed, the conditions are not easily obtainable for a wide range of variation. The diagrams here drawn are for an assumed case, and the secondary capacity is varied from zero to infinity. Ordinarily, the range of variation would be small, as Dr. Pupin has pointed out, and as has been the result of our own experiments. It is to be hoped that Dr. Pupin, who has experimented so faithfully on simple resonance, will bring out equally valuable results from his experiments in electrical consonance.

In addition to the effect of consonance, the action of a condenser to counterbalance leakage has been pointed out above. Although scarcely germane to the present discussion, we may call attention to another effect which may be produced by means of a properly proportioned condenser in the secondary circuit. If the secondary reactance be made zero (inside and out of the transformer), simple secondary resonance is obtained, and a constant primary current will transform to a constant secondary E.M.F.

PRESENT RANGE AND ACCURACY IN THE MEASUREMENT OF ELECTRICAL RESISTANCE.*

BY HERSCHEL C. PARKER.

The measurement of electrical resistance may justly claim one of the foremost positions among physical determinations for range and for accuracy. The limits from theoretical and practical considerations we may place at one ten-millionth of an ohm (1×10^{-7}) for the lower, and ten million million ohms (1×10^{13} or 1×10^{7} Ω) for the higher—that is, a range from one to one hundred million million million (1 to 1×10^{20}). It should be remembered that this scale is uniform throughout, measurements being easily made in all parts of it with an accuracy varying from 1 per cent. to ·01 per cent. Difficulty only is encountered at the extreme limits. The lower limit is determined by the sensitiveness of the galvanometer and the current available. The higher, also by the sensitiveness of the galvanometer, the E.M.F. used, and the insulation of the instruments.

A few comparisons with other physical magnitudes may, perhaps, prove interesting. The wave length of sodium light is $5{\cdot}9 \times 10^{-7}$ metres. The distance from the earth to the sun is $1{\cdot}5 \times 10^{11}$ metres. The ratio is 1 to $2{\cdot}5 \times 10^{17}$. Hence the ratio of 1 to 10^{20} is the same as that of the sodium wave length to 400 times the distance from the earth to the sun. That is, from ·00059mm. to a distance that would require more than two days for light to travel. Again, taking a copper bar, the area of the cross-section being equal to 1·6 square centimetres, we may measure the resistance of a length from 1mm. to 10^{17} metres. A distance requiring about 10 years for radiant energy to traverse, moving with the velocity of light.

In the determination of mass a parallel case would be from 0·00001 gramme (shown by the most sensitive balance) to 10^{12} kilogrammes (equal to about one billion tons. The ratio of one gramme to the earth's mass is 1 to 1×10^{27}. In the measurement of length the different light-waves may easily be determined and stellar distances accurately calculated ; but it would be hardly possible by laboratory methods to measure any given intermediate distance.

It may be well to outline a few of the methods used in determining electrical resistance. For resistances varying from 0·01 ohm to 1,000,000s ohm we have the universal Wheatstone bridge method. For low resistances, some method independent of leads and contacts must be employed. Hence we must use fall of potential measurements, and avoid any error which may be caused by variations of the current. This may be accomplished in the following manner : across the copper bar whose resistance is to be measured is placed a Thomson or a d'Arsonval galvanometer, and in series with the low resistance is placed an ammeter. Now, suppose the galvanometer and ammeter are read at the same time, and that a current of 10 amperes was used ; then

$$R = \frac{E}{10}.$$

The value of 1deg. on the galvanometer scale should, of course, have been previously determined in fractions of a volt. A Thomson galvanometer of 10,000 ohms resistance may have a figure of merit of 50,000 Ω. Then a deflection of 1deg. would correspond to a potential difference of ·0000002 volt across its terminals, and R would equal $\frac{\cdot 0000002}{10}$ × deflection. If a d'Arsonval galvanometer whose figure of merit was 500 Ω and resistance 500 ohms was employed, then 1deg. deflection is equal to ·000001 volt. Low resistances may also be determined very satisfactorily by the Thomson double bridge method. For very high resistances we have the usual deflection method. If a galvanometer whose figure of merit is 50,000 Ω be used and an E.M.F. of 200 volts, we obtain a constant of 10,000,000 Ω. It is hardly necessary to state, however, that the measurement is really limited by the insulation of the apparatus.

The greatest accuracy is attained in the comparison of standard ohms by Carey Foster's method. Here an agreement of results to even ·001 per cent. may be reached. For a great majority of resistance measurements an accuracy of 1 per cent. is all that is desired, even though with care a higher might be obtained. The limits of measurement that have been given above seem to be justified by the present state of the science, but it seems probable that they may be considerably advanced by the use of special methods.

Vol. XIV. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers or binding can be obtained, price 2s.

THE DUTIES OF THE TECHNICAL PRESS.

The policy of the large daily papers has now reached such a stage of finality that little change is to be expected in their methods of procedure. Papers of one political creed are allowed by common consent to write strong leading articles with the professed object of exposing the personal and political weaknesses of the gentlemen who hold views different from theirs. The effect, although often hard on individuals, tends to the cleansing of political life. Technical papers have few such duties to perform, but the superabundant knowledge possessed by their editorial staffs is apt to lead them astray. It would be difficult to find, say, a Liberal paper regularly exposing the weaknesses of its leader's hand. Yet we regret to acknowledge that the electrical Press is repeatedly guilty of this fault. Any information tending to correct faults found to exist in the manufacture and running of electrical plant we welcome heartily, but such fine investigations as lead to the publication of the fact that a steam joint blew in a certain station, which caused the pressure of the supply to fall half a volt below the Board of Trade requirement for one and a quarter minutes, do not further the advance of the industry of electric lighting. Other interesting details as to why the lights in the same district were extinguished for a few minutes may follow soon after the above, and in this way the general idea is spread that a certain supply company is in a bad way, whereas the company may be supplying a light far more regularly than the gas supply in many provincial towns. We say emphatically that those gentlemen who have nothing better to do than to pick holes indiscriminately in everything they come across are a curse to the profession. We require our staff to bear in mind the following outlines as to the duties of the technical Press, and hold that a uniform acceptance of the same would be beneficial—*i.e.*, that the ends for which our paper is published are to foster the industries connected with it by giving prominence to all new work successfully accomplished; to give technical information to those engaged in the profession of electrical engineering; to publish as promptly as possible the advances made in methods of increasing the utility of the profession; and to protect the untechnical public from fraudulent adventurers. These are wide-reaching requirements, and are at times given a somewhat loose construction; and, again, as in many other matters, it is easier to learn what to do from a statement of what not to do.

In this connection we agree with several prominent engineers in the profession that it is not the duty of the technical Press to chronicle the breakages of the governor belts in electric lighting stations, nor the flickering of an erring arc lamp. Mr. Preece informed us at Cheltenham that he has had some six thousand street boxes for telegraph purposes under his charge in London for years, and that explosions due to gas occur more frequently than we care to state. But he also stated that during that time no one has been in any way hurt by these explosions, as also no one has been hurt by

Digitized by Google

the explosions in the electric lighting street boxes. He facetiously added that the horse that expired in Cannon-street died from fright. That fright has by the injudicious action of the technical Press been spread through the length and breadth of the land, and every member of electric lighting committees is anxious to know if their towns are likely to be devastated by such explosions. Provided the lids of the boxes can be lifted easily so that the force of the explosion can be easily dissipated, no harm is to be expected even should the gas get the better of the ventilating gear.

Again, it is not the duty of the technical Press to assist any budding consulting engineer in gaining notoriety by publishing the defects in the supply furnished by the leading electric lighting companies. If the gentleman doing this sort of thing had devised any means of preventing the irregularities which may exist, it would be a different matter, but otherwise the information is abortive. Further, no useful ends are attained by damning a gentleman who reads a paper before an engineering institution because the said gentleman has sufficient information by him to fill more than one paper a year. The expression of the President of the Institution of Electrical Engineers at a recent meeting on this subject has our full endorsement. It is not the duty of the technical Press to run amuck amongst those members of the profession who, perhaps, are not blessed with that superabundance of knowledge possessed by every office boy on their staffs. A want of that knowledge may lead to mistakes, but an honest endeavour to forward the industry should not be recklessly condemned. The last negative clause is perhaps as important as any two of the preceding together. A technical paper should not be bound or controlled by a clique, or by any association of contracting firms. The editors of such papers, although they may be able men, are tied hand and foot, and must give unfair prominence to certain subjects. The result is, that the general public are deceived. It is a matter of difficulty to hold the balance even without the control referred to above, but when a man has to please certain contracting firms, or a clique, in order to retain his position, his paper descends from being a technical paper into a puffing circular.

DUBLIN TRAMWAYS—OUR LEADER-WRITER'S REPLY.

Our leader of May 17 with regard to the Dublin Tramways report has drawn forth a somewhat heated letter from Mr. James L. Owen, which we printed in our last issue. We are led to understand that Mr. Owen has had an extremely wide and intimate acquaintance with electric traction, and we cannot but appreciate that his "certain knowledge" of such matters forces him to express his disagreement with us in terms which are, to say the least, discourteous.

So far as we are aware, the opinion we expressed—viz., "that economical and efficient operation can best be secured by a trolley wire over the centre of the car roof"—is most thoroughly sustained by practically all electric traction engineers, whether European or American. We would suggest that the line at South Staffordshire is by no means a thing of yesterday; that it has been visited in all probability by representatives of most of those constructing companies which are now engaged in traction work; that the methods there adopted have been given wide publicity through the technical Press and the publications of learned societies; and that, notwithstanding these facts, this method of line suspension has been followed only, to the best of our knowledge, in the Bristol line now under construction by the British Thomson-Houston, Limited, and there to only a limited extent. In that city, the authorities refusing a span wire, bracket-arm poles placed either between tracks or along one kerb have been adopted, but the desire to get car and trolley wire as near together as possible is shown by the fact that bracket arms ranging from ten to twenty feet in length will be used wherever the line is supported only from one side of the roadway.

Mr. Owen undoubtedly over-estimates the danger that lies in the possibility of span wires breaking and falling into the street. Such accidents are of the rarest. It is true that top-seat cars are not in *general* use throughout the United States, but it is also true that they are successfully employed on the Californian lines with a span-wire system of construction, and that their popularity is steadily increasing. If span-wire accidents were of the frequency which Mr. Owen's alarmist statements would indicate, the question as to whether roof seats be used on a line or not would matter little. A falling line would be quite as dangerous to the travelling public in other vehicles in the streets as to those who happened to occupy a slightly more elevated position.

We are quite willing to apologise for having wounded Mr. Owen's feelings by referring to the South Staffordshire as a "country line," and to concede that, even if the greater part of its route is along country roads, it does pass through several considerable towns. Most terms are relative in this world, and we merely desired to indicate our belief that the conditions were decidedly unlike those which would maintain in such cities as Dublin, where the most efficient service must be secured to the public. Notwithstanding the confidence with which Mr. Owen asserts that local authorities will not countenance the span wire, the fact remains that sixteen miles of tramway track are now being electrically equipped with span-wire suspension in Dublin and its suburbs.

Let it be understood that we quite appreciate the æsthetic objection to the span wire or to any wire of any nature in a city street. As we have already said, we greatly prefer the centre-pole method of suspension (which is no more obnoxious than the system of lighting from poles at refuges used in London highways) wherever there can be space enough secured between the tracks, but we certainly do not believe that the sole function of a city street is to please the æsthetic eye, and we do believe that its first use is to afford the best and most rapid method of transit, and that within reasonable limits nothing should be allowed to stand in the way of that end being attained.

Digitized by Google

We are sorry to disagree with Mr. Owen; sorry that his experience and "certain knowledge" differs from that of possibly more prominent traction experts; sorry that our "inconsistencies" and "power of making statements which are unsupported by facts" have brought down his criticism upon us; but our sorrow is greatest that he should express himself with needless intemperance when referring to a wholly unprejudiced opinion even if it be at variance with his own.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

DUBLIN TRAMWAYS.

SIR,—Who is Mr. James L. Owen, of 120, Colmore-row, Birmingham, or am I so deficient in that little grain of faith that I am unable to recognise the high priest and apostle of electric traction when he does arrive and preaches in the wilderness that there is only *one* system of overhead traction, and of this he is the prophet?

Although recognising the great responsibility I incur in not accepting the dictum of a prophet, I desire, as a fellow-sinner, to extend my practical sympathy to you in your lost condition by adding my protest to yours—to that portion of Mr. Hammond's report which recommends the South Staffordshire system as the best.

I am, I fear, so case-hardened in my infidelity that, unlike Mr. Owen, I feel strong enough in experience as to have no intention of damning the South Staffordshire system to prove the merits of any other system. On the contrary, I desire to give all credit to those who were responsible for the South Stafford installation, and for the ingenious way in which the prejudices of the local authorities were overcome (if it was the local authorities who had to be overcome).

No doubt the case was a hard one. The tramway company was weak financially, and the local authorities knew it, and Mr. Dickenson no doubt wisely advised his company to agree to this system rather than close the lines, even if it did mean the introduction of an untried system on a doubtful principle and certain loss in mechanical efficiency. But, as you say, this case should not be put forward as a precedent. The engineer who sacrifices his principles to the whims of a local authority is lost; it is like the preamble of a Bill, so capable of proof until the sting of the clauses is felt which are more or less disastrous according to the financial constitution of the promoter and his fighting capacity.

In these days it is sad to contemplate the low estate to which the engineer has fallen since the days of Stephenson, Brunel, Bateman, and others. Now he is the peg on which a company hangs its conscience, the respectable signatory to other people's reports, the advertiser to somebody's system, who does not scruple to jeopardise the success of his works by pandering to the pet theories of ignorant councillors, and who, under the mystic raiment of a 5 per cent., covers the nakedness of the large profits of the contractors with a semblance of professional philanthropy.

I am not prepared to raise any question as to which system of overhead traction is advisable for Dublin, but I am prepared to suggest there may be cases where it might be somewhat difficult to apply the South Staffordshire trolley, especially in Sackville-street, which, for the conductor to be anywhere near the kerb, would necessitate a trolley arm 40ft. to 50ft. long.

No, Sir, the progress of electric traction in this country is considerably handicapped by the ridiculous contentions of engineers who have systems of their own to ride—and their name is legion. It is the duty and policy of the engineer to advise according to the particular conditions and requirements of the district. This principle is not going to be altered because Mr. Owen thinks the fire-escapes cannot be modernised to suit the march of progress. Leeds has the span-wire system and is proposing to extend it; Coventry, also. These towns apparently do not appear to share Mr. Owen's views. In London millions of passengers travel annually by 'bus and tram under a network of telephone wires without this suggested fear of wholesale decapitation.

Mr. Hammond's experience in the erection and working of overhead electric traction exists at present mainly in theory. It may be that with some practical experience he will change his ideas, which are as numerous as the colours assumed by the caterpillar as a protection when feeding on various shades of green. His suggested close relationship between traction and lighting is one of them, and can be considered at present as seriously as another one he suggested to the Municipal Corporations Association, that he would get over the difficulty of the overlapping load in working tramways from the central lighting station by the employment of horses during that period.

Mr. Owen should learn that the removal of the mountain depends very much on the material composing it, and mountains of ignorance and prejudice are easily converted into molehills by public requirements and the common-sense advice of the engineer who has no system to ride.—Yours, etc.,

STEPHEN SELLON.

ELECTRIC LIGHTING OF TRAINS.

SIR,—Referring to the article on p. 586 of your last number, I beg to point out that it was in November, 1883—not November, 1884, as stated—a District train was fitted with the electric light, and that the experimental running in public took place in January and February, 1884. The engine, "as used with a Siemens dynamo in 1881," was *not* a central-valve engine (as the writer of your article was assured by Mr. Crompton), and the date should be 1883-4. I recommended the use of an engine and dynamo fixed on the locomotive, but the whole of the motive power and gear were placed in a guard's van in order that the company might obtain full particulars of working cost.—Yours, etc.,

W. H. MASSEY.

25, Queen Anne's-gate, S.W., May 28, 1895.

P.S.—I note on p. 595, in your report of the discussion on Mr. Robinson's paper, that Mr. Crompton bought his first Willans engine 19 years ago. It would be interesting to have the exact date, and to know what the engine has been used for. I remember trying a Willans engine coupled to a Weston dynamo which I took to Thames Ditton in 1882—only 13 years ago, and I had tried several of these engines for other purposes more than 20 years ago, but I cannot trace the engine mentioned by Mr. Crompton. The four 50-h.p. sets were supplied by Messrs. Willans and Robinson to Buckingham Palace in 1884, being some of their earliest electric light engines.

OPPORTUNITIES IN ELECTRICAL ENGINEERING.*

BY A. A. ATKINSON.

(Concluded from page 601.)

There has been a great deal said by way of discussion as to whether it will be most in accord with the fitness of things to educate the student along broad and general lines as a basis, and allow him afterwards to specialise in any direction he may wish, or to train him directly in the applications with which he must have to do, only giving him enough of the technicalities to serve as a basis for future work in case he should have the opportunity or inclination to pursue such a course. These may properly be classed as technical and practical courses. In other words, I shall call technical that course of study in which are included a rigid course in higher mathematics, advanced mathematical physics, the higher mathematical theory of electricity, and much mechanical engineering. These fill up most of the first three years of the course. The fourth is devoted to laboratory work in measurements, dynamo tests, engine tests, lectures on the telegraph, turbines, heat engines, and finally a thesis. The entrance to such a course generally requires of the student qualifications such as would admit him to the

Digitized by Google

freshman classes in any literary or scientific course. On the other hand, I shall call practical that course of training in which the mathematics, physics, chemistry, and mechanical training all look toward the engineer in practice, and which includes such parts as will be directly available for him in his everyday work, leaving the refinements for his own individual filling in afterwards, instead of teaching him the refinements and sending him out to fit some of it, if he can, to whatever application he may.

By way of further suggestion of the distinction from the purely technical, let me say that the practical course will include lectures and practice in wiring for the various kinds of distribution for lighting and power; calculations for alternating and direct current wiring under various conditions; the theory and application of electricity for railways, stationary power, lighting purposes, including the modern types of machines—direct, alternating, and polyphase; designing and calculations for the winding of dynamos and motors; theory of steam, with practical instruction in the care and operation of boilers and engines, dynamos and motors. His knowledge of lighting and power distribution will be enlarged by model plans and specifications drawn up by him to meet certain requirements in railway and central and isolated station work. More and more detail will be required in this as the student progresses, until he is able to draw and specify for actual work. We could go on further in contrasting the two lines of study, but it will be apparent to almost anyone stopping to give the matter any consideration what their distinctive features must be. The one a very general basis upon which any application may be built by a sort of second experimental training, while the other is intensely practical in all its aims and work. The one may develop the theorist, the electrical investigator, the electrician; but even here real practice in the bone labour of the profession would be of much benefit. The other will produce the artisan, the superintendent, the installing and consulting engineer. So that, assuming in both cases that the student has been apprised of the difficulties and necessities—in short, the real situation confronting him—in order he may not go out with puffed or false ideas, each course prepares for a different line of work. Of course, the one line may develop afterwards into the other.

The question now is, with conditions as they are, which offers the most to the young man? So far as it can be seen at present, considering the number of positions open, the practically educated young man has the advantage, though if the technical graduate be willing to begin low in order to learn the practical elements of the business and to convince his employer of his superior ability and skilfulness, he will find plenty of opportunities for promotion; he can then leave the lower position to another beginner. But unless he be willing to do this, the practical man, who is in a sense previously prepared for work in any application, has much the advantage. Besides, he knows the practicalities, the other has them yet to learn.

I believe the day is past when we should expect new and wide applications to develop suddenly to require the services of a number of men; the surprises in lighting and power transportation are not in the future. When these things were new, men not educated had to fill the positions; horse-drivers became motormen, fire-stokers station men, and steam engineers "electricians." Now, as these industries widen, and that rapidly, the great problems are a more efficient service, stricter economy in all directions, and a gradual weeding out of the undesirable, thus making room for those prepared to render the best service. Necessarily, this process has been slow for several reasons, but now that the various departments of the electrical business have become permanently established, this will be more rapid. The bad wiring, the wretched installation, the miserable economy of operation which have prevailed in the majority of cases in light and power plants for small towns, and also in very many not so small, will gradually disappear, because the services of trained men are beginning to be appreciated and sought. For the same reasons new installations will be manned by those who are prepared for the work.

* From *Electricity*, New York.

I can probably best indicate the situation to the electrical student by outlining the kinds of positions that may be open to him. So not by any means including all, but serving as a broad basis of division, let us lay down the following: (1) original investigation and invention; (2) consulting and constructing engineer; (3) superintendents of light and power plants, including isolated and central-station work, stationary power, railways, mining, etc.; (5) artisans in light and power; (6) artisans in factories. Those belonging in the first class I shall call electricians; those in the second, third, and fourth classes may properly be denominated electrical engineers. To be sure this is not meant to consider those cases where some member or stockholder of the company is made "superintendent" whether there is an engineer besides him or not. If he has not the electrical knowledge, and does not actually superintend the electrical part of the work, his title is a misnomer. Properly, in small towns where this is done, he should be superintendent or business manager of the "company," and not of the plant or works. It will be quite evident also that the station man in a small plant who also looks after the wiring and general repairs, is not entitled to the distinction of electrical engineer. He is merely an artisan, and the plant and town are without an engineer.

I assume in this connection that only he who has practically passed through the preceding steps and has arrived at the point of being the real superintendent of all the construction and repair of electrical appliances, whose theory and practice and experience entitle him to this distinction, shall be called electrical engineer in the sense in which I am using the title. Under (5) and (6) I mean to include all, highest to lowest, engaged in actual work in manufacturing establishments, and in the actual operation of electrical appliances in lighting and power.

As to numbers, we observe that those belonging to class (1) are comparatively few. Their preparation will be of the highest kind, technical and theoretical. The work of research must be undertaken only by those who have an intense love of truth for its own sake, and are willing to devote many weary days to its search with the expectation of no other reward than the great satisfaction of having added something to the world's knowledge. Science may indeed pause to do them tardy honour. Men of this stamp we all can name, and none are more deserving of the world's gratitude for their noble sacrifices in behalf of truth. Such men have established the laws of chemistry, physics, and electricity—indeed, have built the foundations of knowledge in all lines. They have established the bases for the modern practical applications of science, and they have invented practical devices for applying their discovered principles. They have given us the photophone, the phonograph, telephotography, the telautograph, the possibilities of electrical welding, heating, cooking, transportation, and hundreds of others. And yet their work is not done. There are the problems of light without wires, the real nature of electricity, light and power without the present wasteful methods—perhaps by maintaining very high-frequency vibrations — electrical energy directly from the sun, methods of improving the magnetic circuit of dynamos, earth telephony, etc.

Very little need be said about class (3), for the number of places is necessarily limited, being open generally only to those who have received a special training in the factory itself. New establishments select men of experience from factories elsewhere. But those who are fortunate enough to secure places as artisans are the material—some of them—out of which those more enviable men are made.

There are much greater opportunities in class (2), and these will be on the increase. As the tendencies are more and more to stricter economy, least first expense, and more efficient service in general, the electrical engineer will be more and more in demand. The time is rapidly approaching when every central station, lighting and power, and every form of electrical business will have their consulting and installing engineers. The preparation for this work must be founded in practice. Without going into detail, it is apparent that the technicalities of engineering alone will be of little avail. The reason for many failures in the successful installation and operation of electrical plants has been that the "theories" of those in charge were not

Digitized by Google

backed up by a thorough practical knowledge and experience.

Classes (4) and (5) have the advantage of by far the greatest number of individual opportunities; and as the financial condition of the present improves this will be true in a still larger measure, since capital being less conservative will hasten to invest in the business which, when rightly managed, promises the largest per cent. on the outlay. The gradual adoption of electricity by steam roads and by new competing roads joining important centres, the rapid extension for lighting into towns everywhere, the enlarging of existing plants to meet the exacting demands for greater and better service, the extension of electric power into mines and other forms of industry—all will have the effect of opening up new and wider opportunities. But in the same proportion there will be the greater demand for more thoroughly prepared men. This needs no particular illustration; but to take a single instance, lighting, as representative of the situation in general, it has been stated on good authority that if electricity should supplant gas for lighting purposes the cities of New York and Philadelphia alone would at once require all the dynamos and lamps now in use in all the United States. I believe this is what we are gradually but surely coming to. With the inevitably cheaper production and more satisfactory results gas must die hard after a severe struggle, the Welsbach with its other devices. It can readily be seen what the advantages of electricity are, and the people will demand and get it. It needs no argument that the preparation for these two classes must be a thoroughly practical one—practical in the sense in which I have been taking it.

Under the head of (6) comes a number of positions, though much smaller than under (4) or (5). On the whole these places are not so desirable, since the chances for advancement will be limited to very few in this line of work.

From the foregoing outline it will be apparent that the men educated along what I have called practical lines have far the better chance for promotion under the present conditions, and the places they are at once able to fill are much more numerous. The technical graduate is prepared for (1). True he may work in (2) and the rest if he first goes to work to prepare for them by practical study and experience, either in school or under private instruction, with an apprenticeship. This done, his higher instruction will be of much advantage to him. But I cannot help deprecating the tendency of our so-called technical schools in their instruction to sail off into the generalities, refinements, and abstractions to the neglect of those things which are more essential for the immediate use of the great majority of their graduates.

I wish to repeat that there are and will be opportunities abundant for those rightly educated. In numbers they compare at least very favourably with those in other professions. Students must, of course, be taught the difficulties of low salaries at first—not speaking of the many favourable exceptions to this—hard work, and perseverance. But is this any less true in most other kinds of business as a rule? One great reason for the apparent overcrowding of the electrical profession is that so many are educated for positions that do not exist instead of preparing to meet the conditions as they are.

ALTERNATING AND INTERRUPTED ELECTRIC CURRENTS.*

BY PROF. GEORGE FORBES, M.A., F.R.S., M.I.C.E.

LECTURE III.

(Concluded from page 603.)

Now, I can bring before you some other illustrations of the same sort to show you that the skin resistance may become very high indeed, and may even almost prevent an electric current from passing through a good solid conductor. This is really an explanation of the experiment which was made by Faraday so long ago, in which he had a wire going round the room and separated by a few inches where the two ends came together, into which an electrical discharge from a powerful Leyden jar was sent at the two ends, when the discharge preferred to cross the air-space rather than to travel round the copper conductor, although that was an excellent conductor. That was owing to the suddenness of the discharge, and the experiments I am going to show you are illustrative of the same fact. To show it, perhaps, in a more complete manner, I will take a copper arch (Fig. 30)—this is one of Mr. Campbell Swinton's arrange

Fig. 30.

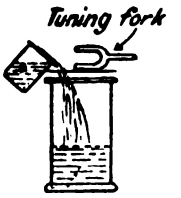

Fig. 31.

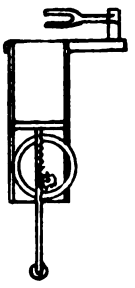

Fig. 32.

ments for which I am indebted to him—and I will send into it an oscillatory discharge. I have the means of producing very rapid oscillations in the apparatus before you. The terminals will be connected with the two ends of the arch at the base, and there is an incandescent lamp stretched across the two vertical pillars which form the sides of the arch. Any person looking at this in relation to the ordinary method of using currents would say, when we applied the current it would all flow through the thick arch and none would flow across this very high-resistance lamp; but, as a matter of fact, the resistance opposed to these very high oscillations becomes so great that it is very difficult to get the current to go up the whole length of this wire, and still more difficult to get it to go right round, and instead of going right round by that thick conductor, which would offer a certain amount of skin resistance, a great portion of the energy prefers to go across that thin filament where the skin resistance is not so predominant a feature. [*Experiment.*] At this height, you see, comparatively little of the current is able to go through the lamp. When we bring the lamp lower down, nearer to the terminals, we get more and more of the current able to pass through the conductors up to the lamp, and when we bring it down low enough we are able to get the lamp up to its full incandescence. But a mere removal is enough to prevent the current passing along the conductor sufficient to light up the lamp.

Now that I have explained to you the nature of skin resistance, and I have explained how it was produced owing to its being a solid conductor, in order to demonstrate this to you better I will now take a strip of copper instead of a piece of solid circular section. This strip of copper is of exactly the same weight per unit length, it is the same section as the wire, and it is of the same conductivity. And what I wish to show you here is that the induction of one part on another is not such a serious matter in the case of the strip, where the distances are greater than in the case of the wire, where they are all very close to the central part of the section. We will now put on the current. There, you see that the current is able to pass through the copper strip much more easily at the top than it was before. The light is very dim, but as I gradually lower the lamp, gradually there is more light. The lamp, however, is not yet at its full incandescence, and it is only when I bring it down near to the base of the arch that I am able to get sufficient current through the lamp to bring it to its full brilliancy. The difference between the copper strip and the solid copper rod is most marked.

Now, I will show you the effect with an iron rod, and in this case I have chosen an iron rod of such a section that it has exactly the same conductivity as either the copper rod which I first used or the copper strip which I used in the second place. And here the opposition to the passage of a current is very much greater than in either of the cases which we had before, as will be obvious as soon as I put the thing into action. [*Experiment.*] Gradually, as we lower it, it is coming towards its full brilliancy; but you see when the lamp reaches the same level at which in the first case it arrived at its full brilliancy, it has not arrived at its full brilliancy in this case simply for the reason that the iron between the lamp and the terminals offers such an amount of opposition that there is very little current able to pass through the lamp even at that height, and we have to lower it very low indeed before it arrives at its full brilliancy. These three experiments illustrate in an extremely good way the general character of the phenomena of skin resistance, which not only from a purely scientific point of view are of great interest, but also require careful consideration in dealing with engineering problems.

Now, passing from skin resistance, I wish to talk a little—

* Lecture delivered before the Royal Institution.

Digitized by Google

I cannot very well show you electrical experiments, although I shall show you experiments illustrative of electrical oscillations—about the phenomena of electrical resonance, such as the rise in pressure noted some time ago on the conductors running from Deptford to London, owing to the considerable capacity of the mains used. You will see the distinction I draw between effects of resonance and oscillations. Let me introduce the subject by saying a few words about ordinary resonance. I have here a spiral spring suspended from the ceiling to which I can apply a force at regular intervals. And I will show you that when I apply a very small force to the spring at regular intervals it accumulates the energy, and eventually gives rise itself to a much greater force than that which I had been imparting to it at each individual motion. And also you will see that the velocity of motion after I have repeatedly given an impulse to the spring becomes very much greater than it would be with the same force applied at a single effort. The reason of this is that the spring is capable of oscillating in a perfectly definite period. The period of oscillation depends upon two things—it depends, first, upon the elasticity of the spring, which tends to draw it back when once it has been displaced; and, secondly, it depends upon the mass or momentum of the spring, which resist the movement. These are the only two things that come into play in this spring. There is no friction. It is not in a vessel of oil or anything of that sort which would produce friction, and the electrical analogy is simply a circuit in which there is capacity—that is, the elasticity part of it—and self-induction—that is, the momentum part of it. Just as with the mechanical spring, when we know the mass and elasticity of it we can calculate the period, so, substituting for mass and elasticity the electrical units which I have given on the table, you can calculate what the period of an electrical oscillation is also. [*Experiment.*] I exert a very slight force upon it at each stroke, and, you see, before I have taken more than two or three strokes its motion is increased to a very considerable extent. The oscillation of the spring now in its own period is very violent indeed—that is to say, the current that is flowing through that electrical system is very much greater than that which is due to the E.M.F. That is the real interpretation of the increased velocity of the spring.

I will now give you another illustration of electrical resonance. I take for that purpose a jar (Fig. 31) containing a little water, and also a certain amount of air. The air is capable of vibrating, and if the length of the jar is fixed it is capable of vibrating in a perfectly definite period. When I cause a tuning-fork to vibrate, and hold it over the mouth of the jar, it sets the air at the upper part of the jar vibrating; this vibration communicates itself to the air in the lower part, and it is then reflected from the bottom just in exactly the same way as that spring was. The air at the top of the jar represents the free end, and the water being fixed corresponds to the ceiling. I will now show you that the air in the jar will resound to this tuning-fork, and greatly increase its sound. The period that it will resound depends upon the length of the column of air. [*Experiment.*]

I used then a tuning-fork of low note. Here I have one of a higher note, and you will see that this column of air will no longer resound to it, and we must find a column of air of different length which will do so. I will cause the tuning-fork to vibrate, and then get Mr. Mitchell gradually to fill up the jar with water. As the water is poured in you will find the sound gradually increases, until when we reach a certain length the resonance is complete. [*Experiment.*] Knowing the elasticity of the air, and knowing the weight of the air, we can calculate the period just the same as we can in the case of the spring, and so we can in any electrical system where we know the farads and the henrys. As in the case of the spring and the air, the period depends only on the elasticity and momentum, so in the electrical phenomenon it depends on the capacity and self-induction, and not upon the resistance. The resistance may tend to dim the resonance, but does not alter its period.

As an illustration of ordinary resonance, I will show you an apparatus (Fig. 32) which I got out some time ago for measuring the amount of firedamp in the coal mine. It consists of a tube, whose length I can vary by means of a wheel, and tuning-fork which resounds to it. [*Experiment.*] There is no resonance now; there is now; there is none now. I pass through a maximum of resonance. I adjust the length of the tube by turning the wheel till I get the maximum, and I read by the index that there is no firedamp. The elasticity of the firedamp is the same as the elasticity of the air, but the mass that is to be moved is not so great, and therefore it will move more rapidly than with the same column of air in it.

Leaving the question of electrical resonance now, the last feature of interrupted and alternating currents which I wish to show you is oscillations. In order to illustrate the phenomena, I have prepared a model to carry out our analogies. These oscillators which I am going to use consist of a capacity and a self-induction which are so chosen as to give a very rapid period of oscillation, so that effects are produced by an alternating current with these oscillators which could not be produced by the alternating currents alone. I will now show you by means of a simple model what the character of these is. I have a spring which you see here (Fig. 33). It has a natural period of oscillation. I have applied a strip of paper to the piece of watch-spring, so that I can blow against it and produce a disturbance. The velocity of the motion represents the amperes of the current; and what I want to show you is that I can get far more powerful currents from this by a broken current than I can by using an undulatory current. I have arranged it so that in the first place I move a jet of air up and down so as to be undulatory in it character. [*Experiment.*] There, now notice the amount of the motion and the amount of the velocity. You notice it moves backwards and forwards as the air pressure increases, and the velocity is comparatively slow.

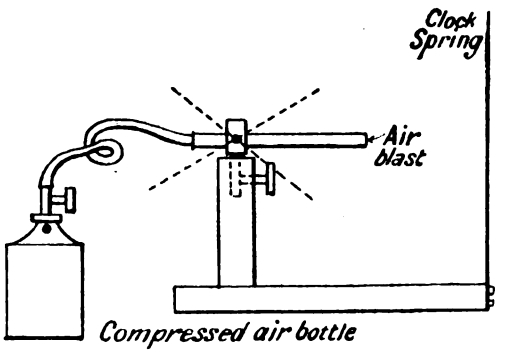

Fig. 33.

Now, I am going to use the same jet of air, but instead of passing it so as to be continuously pressing upon it, but with more or less force, I am going to pass it across the spring so as to be acting upon the spring only for a minute space of time, and then leave it to its own oscillation. [*Experiment.*] There, you see the velocity is 100 times as great as it was before, although the amount of pressure which I am applying summed up over a second is not nearly so great, and yet I get enormously more velocity than I did before when I was applying an undulatory current. In the electrical analogy, if I have an oscillating system I am able to produce a far greater current by allowing it freely to oscillate than if I apply a gradually increasing and diminishing current to the system.

Now, as an illustration of this I will show you an experiment with the oscillatory discharge. These oscillatory discharges of high voltages have been used so frequently of late years that I suppose most people have seen them. At the same time they are very instructive experiments, and it will not take but a few moments to arrange them. I just wish to show you the lighting up of a tube (Fig. 34). The experiment was first shown in

Fig. 34.

this room extremely well by Mr. Nikola Tesla, of America, some few years ago, and it has justly gone by his name ever since. The oscillations are transmitted through my body and are able to light up the tube. [*Experiment.*] Here you see the tube lights up through my body, and the oscillations are shown by the intervals of light. It lights up only when the discharge has taken place, and you are thus enabled to see the nature of the oscillatory discharge.

I have now come to the end of the experiments which illustrate this part of my subjects, and I feel sure that those of you who have listened to these lectures, and have seen the admirable arrangements which Mr. Campbell Swinton has made, will not be disappointed if I show you another experiment, using the same apparatus but not connected with the subject of the lecture. The experiment is a very remarkable one, and is originally due to Lord Armstrong. He first found it out when using a hydro-electric machine in which he got great currents at high pressures by means of a jet of steam. In the arrangements which I am showing you I get the high E.M.F., or rather Mr. Campbell Swinton has obtained it, by using an induction coil, and using a continuous current through the induction coil. In most of the experiments which I have been working before, we have used an alternating current, because if we had used a con-

Digitized by Google

tinuous one we could not have interrupted it rapidly enough. In the present instance we are using a continuous current. From experiments I have shown you before, you know that when we make contact with a primary there is an induced current in the secondary, and a reverse one at break. We are able to almost eliminate the current in one direction, and to thus secure the secondary current almost entirely in one direction; and this is emphasised by having a spark gap which the current has to leap over, and which is wide enough to prevent the spark passing at the make, but not too wide to prevent it passing at the break. This is really an experiment on continuous currents, and not on either alternating or interrupted currents.

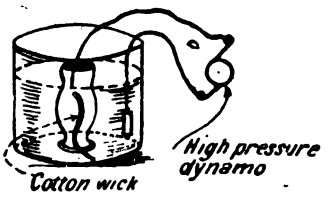

Fig. 35.

In this experiment the apparatus (Fig. 35) is not shown on the screen inverted: it is shown in the same position as it is on the table in front of the lamp. Here, in a square glass trough, I have an inverted bulb, open at the top and open at the bottom, with a piece of cotton wick coming through the narrow neck-like opening at the bottom of the bulb. The wick is at present coiled up in the bulb, and a short end is projecting into the liquid below. The high-pressure electric current is taken to the water outside, and the other terminal to the water inside the bulb. According as I pass the current in the one direction or the other so the cotton wick will be seen to move out of the bulb, or to be retracted again into the bulb; and the most remarkable feature about this is that at the same time that the cotton wick is moving in one direction the water is moving in the other, and by the projection on the screen you will actually be able to see the direction in which the water is moving. In order to carry out this experiment, the purest distilled water is necessary, and provided everything goes well we ought to see the motions easily.

I may say that Lord Armstrong has shown this experiment to a few of his friends, and Mr. Campbell Swinton has shown it to me and others, but very few persons have seen it. I can only say, in explanation, that it is probably due to the same phenomena as electrical endosmose. If you have a vessel of liquid with a septum of porous material, there is an electrical action between the septum and the liquid which tends to draw the liquid through the septum, and it is probably a mutual action between the porous material and the water. Probably this is the same effect exhibited in this experiment; there is a mutual action between this wick end and the water outside, and the mutual action causes the one to be drawn downwards and the other to be pushed upwards. [*Experiment.*] Now you will notice that the water is rising in the bulb, and the wick is coming out at the bottom. We will reverse the current, and as soon as we do that you will see that the action takes place in the opposite direction, and the wick is going upwards while the water is going out at the bottom.

MOUNTAIN-CLIMBING RAILWAYS.

BY ERNEST SCOTT.

(Concluded from page 456.)

The Lauterbrunnen Railway is worked by water ballast, and has a gradient of 60 per cent., the minimum being 42 per cent. It connects the rack railway to Interlaken with the electric railway from Grutsch to Murren. As the gradients vary all the way up, provision is made for equalising the differences in stress on the wire rope by allowing the water in tank of the descending car to gradually run out. A concrete channel in the permanent way carries away the waste water. To guard against the front wheels mounting the rails during the ascent, a pair of grappling irons are fixed to the car, and travel loosely along the underside of the rack flanges. In the event of the car lifting above ⅛in. they clutch the flanges. Two cocks are provided for playing water on to the brake wheels in the descent.

The electric railway from Grutsch to Murren is worked by electric locomotives and overhead trolley wire. Current is generated at 600 volts by a Brown dynamo, direct coupled to an Escher, Wyss, and Co.'s turbine. A noteworthy feature of the motors is that they do not require more than *double* the normal current at starting. This is low, and is due to the spring suspension of the motor, the elastic medium thus provided assisting in overcoming the inertia of the tram. The mean fare for the up and down journey is about 7¾d. per mile, and the total number of passengers carried per day is 600.

Table I. gives particulars of the most important mountain railways that have been laid down. Where separate locomotives are used, they are invariably arranged so as to push the passenger car up the mountain side. The ordinary tee or Vignoles type of rail is almost invariably employed, because the broad flange is easily secured to the sleepers. The steepest gradient is that of the Stanserhorn, 61 per cent., and this is the only line on which the rack has been dispensed with altogether. The cost of construction and equipment per mile of track varies very considerably, from £50,000 to £14,000. In the most recent cable railways, with the winding drums worked by electric motors, it is about £25,500. The percentage of working expenses to receipts varies, with a few exceptions, between 85 and 45 per cent., the average working cost per car mile being 5d. The total weight of permanent way, including rails, rack, sleepers, and fastenings, averages about 200lb. per yard. Creeping of the rails is one of the principal difficulties in laying the permanent way of these lines. It is usual to fix iron anchors, or creep arresters (firmly embedded in the concrete or masonry), to every fourth or fifth sleeper. Owing to the question of stability under wind pressure, the cars are always built of the half-open type with cloth hangings, which in ordinary weather may be drawn, but in case of a high wind must be close reefed. The radius of the curves employed is often very small, and as the wheel base of the cars and locomotives are always fixed it is usual to increase the width of gauge slightly, the outer rail being also raised to allow for centrifugal force. For a radius of 600ft. the gauge would be increased 1-16in., and the outer rail raised ¼in., whilst for a radius of 300ft. the gauge would be increased 3·32in., and the outer rail raised 1⅛in. This is for a 3ft. 3⅜in. gauge; it would, of course, have to be slightly modified for a different gauge and according to the wheel base. One of the sharpest curves employed is that on the Wengern Alp Railway, 197ft., with a gauge of 2ft. 7½in. Steam locomotives usually carry four sets of braking gear, all of which can be operated from the foot-plate—viz., air brake, two rack-wheel brakes, and a steam brake; this latter in the electric locomotive having its counterpart in the electric brake or the motor working as a dynamo. On the Swiss and German railways the important work of putting down the foundations, laying the permanent way, and tunnelling is nearly always done by Italian workmen, who have gained for themselves quite a reputation for good work. They are paid about 25s. per week. The cost of masonry runs out at about 8s. per cubic yard, and tunnelling £16 per lineal yard.

The lines already projected in this country are Snowdon (3,571ft.), Ben Nevis (4,373ft.), Arthur's Seat, and Snaefell (2,000ft.). The site for the line of the first named has already been surveyed and work has commenced. The Abt differentiated rack is being used, and the gauge of the rails is 2ft. 7½in. It is proposed to use a waterfall as the source of power, driving dynamos by means of turbines, the current being supplied to the motor cars at 500 volts by overhead trolley wire. The motor car will carry 66 passengers, and the trailer, which will be used in busy seasons, another 40. The length of the line is about 4½ miles long, and the maximum gradient 17 per cent., with curves of 350ft. radius. The pitch of teeth in rack is 4·72in., and the rack wheels are 18in. diameter with 12 teeth. Two steam locomotives have been ordered and will be used for the construction of the line and for making tests. The Snaefell line will be finished this year.

A good deal of public interest has been awakened in connection with this railway up Snowdon. The Society for the Preservation of Sites of Historical Interest and Natural Beauty have, through Mr. H. D. Rawnsley, of Bangor, published an energetic protest against the railway being built—the following being one of the most telling paragraphs: "What we protest against most, however, is the commercialising of scenery. Snowdon unrailwayed, unvulgarised, and unexploited is a better investment for Wales, for Llanberis or any of the villages that cluster round its base, than Snowdon turned into a mixture of tea-garden and switchback. The love of natural scenery, hardly more than a century old in Great Britain, is working gradually downward into the mass of the people, and the inevitable crowding of the cities, with all the accompaniment of train and tram, as inevitably makes men desire more and more something that is without these accompaniments for their rest and enjoyment." Notwithstanding this strong local appeal, Mr. Assheton Smith, the proprietor of part of Snowdon, who has on several previous occasions opposed railways up Snowdon on æsthetic grounds, has changed his views and now given facilities to the promoters of the new scheme.

It is hardly necessary to point out the almost noiseless working by electricity, and that mechanical structures are not always, if ever, an eyesore—*e g.*, the Forth Bridge, about the design of which so much was said from the æsthetic point of view. In this connection it may be interesting to recall one or two of the objections urged in the Houses of Parliament against the introduction of the steam railway: "The country gentry were told that the smoke would kill the birds as they passed over the locomotive. Even cows, it was said, would cease to yield their milk in the neighbourhood of one of these infernal machines. Sir Isaac Coffin asked what was to become of coachbuilders and harness makers, coachmasters and coachmen, innkeepers, horse breeders, and horse dealers, and went on to say that iron would be raised in price 100 per cent. or probably altogether exhausted. It would be the greatest nuisance, the most complete disturbance of quiet and comfort in all parts of the kingdom that the ingenuity of man could invent."

The question has often been asked, What is the good of rack railways? In reply to this question, we can give the omnipresent if sordid argument that it causes trade and circulates some money. It enables invalids to breathe the invigorating air of the high mountains. It has rendered accessible, with comfort and ease, mountain heights the view from whose summits had before been possible

Mont Generoso	Lugano	5 376	Rack	Abt	Steam locomotive
Rhigi	Lucerne	5,741	Rack	Riggenbach ladder	Steam locomotive
Llanslebourg	Mont Cenis	5,880	Double rack	Agudio	Wire rope locomotor
Wengern Alp	Interlaken	6,183	Rack	Riggenbach ladder	Steam locomotive
Stanserhorn	Lucerne	6,200	Wire rope	—	Electric power station
Mount Washington	United States	6,262	Rack	Ladder	Steam locomotive
Glion-Naye	Geneva	6,397	Rack	Abt	Steam locomotive
Pilatus	Lucerne	6,778	Rack	Locher	Steam-engine car
Scheynig Platte	Interlaken	6 791	Rack	Abt	Steam locomotive
Mount Wilson, Pasadena	Southern California	7,000	Wire rope	Abt	Electric motor station
Central Pacific	United States	7,021	Adhesion	—	Steam locomotive
Rothhorn	Brienz	7,388	Rack	Abt	Steam locomotive
Mainton and Pikes Peak	United States	7,500	Rack	Abt	Steam locomotive

only to the young, sound in body and of athletic tendencies. Those who have seen the little miniature trains slowly toiling up the mountain side cannot but think that, after all that has been said to the contrary, modern progress is no foe to the finer things of life, but an ally bringing to millions privileges and pleasures which hitherto have been denied to all but few. Excursionists whose time is very limited have also to be considered, and although the fare when calculated out per train mile and compared with the ordinary rate of 1d. per mile appears high, there is no doubt, the large and increasing number of people who travel and get their knowledge of the country by excursions will welcome the innovation. These railways give ready access to observatories already built, and by cheapening the cost of transportation will probably be the means of multiplying the number of observatories.

Although none of the hills of these islands look like mountains when compared with the huge and high masses of the Continent, yet there is considerable scope for mountain-railway speculation. For instance, Helvellyn, 3,166ft.; Ingleborough, 2 400ft.; the Peak, 1,800ft.; Snaefell, in the Isle of Man, 2,000ft.; Plinlimmon, 2 500ft., containing the sources of the Severn and the Wye; Ben Macdin, 4,300ft.; Ben Lomond, 3,200ft. These and many others are visited by an increasing number of tourists every summer, and in nearly every case there is sufficient water power available within a radius of four or five miles. It is, however, in rack and adhesion lines with gradients up to 10 per cent, such as are met with on country roads all over the British Isles, that we shall have the greatest and most beneficial development. The cost per mile, including electrical equipment of road railways, 3ft. 3⅜in. gauge, suitable for country districts, is about £6,000 per mile. As an instance may be mentioned the short railway from the Lake of Lucerne to the foot of the Stanserhorn, which cost only £4,500 per mile. It is three miles long, metre gauge, and runs along the highway, leaving 13½ft. for ordinary vehicular traffic. Although there are only 12 trains per day each way, and a resident population of only 3,000, it has already yielded a return of 4 per cent. on the capital. This is an ordinary adhesion line and an exceptionally low cost per mile.

Combined rack and adhesion lines come out considerably higher, from £10,000 to £30,000 per mile, the cost varying according to the gradients, cost of transportation of material, character of rock formation on hilly section, etc. Table II. gives particulars of some of the principal rack and adhesion lines. The question whether simple adhesion or rack and adhesion is preferable depends on local conditions, requirements of traffic, etc.; for instance, the electric tramcars on the Florence, Genoa, and Zurich travel at eight miles an hour up grades of 8, 7, and 6 per cent., depending on adhesion only. It must be remembered, however, that they are only tramcars of the ordinary seating capacity (about 40), and there is no special provision for luggage.

The light railways for serving agricultural and country districts which are being talked about at the present time will probably have a train load of 60 to 90 tons, and besides giving seating capacity for 200 will have several luggage vans. For such railways the combined rack and adhesion system will be found to be the most suitable—the adhesion gradients being worked up to, say, 3 per cent. and rack grades from that up to 10 per cent. or more, if necessary.

Now that the much-talked-of Jungfrau Railway is again to the front, it may be interesting to recall Colonel Locher's ingenious suggestion for carrying passengers above the perpetual snow-line. His device is that two circular tunnels be cut as nearly straight as possible, through which the cars, acting as pistons, are pushed up by compressed air, the air being supplied by centrifugal fans at about 1½lb. per square inch. He estimates that the ascent of the Jungfrau could be accomplished by this method in about 15 minutes at a speed of 15 miles per hour.

A short bibliography is appended, which will be useful to those who wish to follow the subject further. Mr. du Riche Preller is the best English authority, and his writings on this subject are very extensive. Authentic data with regard to costs of construction and maintenance, etc., can be got from the statistics which the Swiss Federal Government publish from time to time.

TABLE I.—PARTICULARS OF SEVERAL MOUNTAIN RAILWAYS.

Name and location.	Year of opening	Length, miles.	Maximum rise in feet.	Highest point above sea-level in feet.	Gauge.	Weights.	Rails.	Rack.	Gradients.	Speed in miles per hour.	Number of passengers.	Cost of line.	Cost of line and equipment per mile.	How worked.	Remarks.
Righi-Vitznau, Lucerne, Switzerland.	1871	4·35	4,200	5,741	4ft. 8½in.	Engine, 12½ tons; train load, 28 tons.	35lb. per yard.	Riggenbach's ladder.	Average, 22 per cent.; maximum, 25 per cent.	3	82	£89,400	£20,416	Steam locomotive.	Vertical boiler; locomotive separate from passenger car.
Mount Pilatus, Lucerne, Switzerland.	1889	2·77	5,382	6,778	2ft. 7½in.	Total train load, 18 tons.	40lb. per yard.	Locher's double rack back-to-back.	Average, 36·6 per cent.; maximum, 48 per cent.	2·2	35	92,460	35,904	Steam locomotive car.	Car wheels without flanges; locomotive and car in one; boiler horizontal, placed transversely to track.
Maniton and Pikes Peak, United States.	1891	8·75	7,525	14,300	4ft. 8½in.	Engine, 32 tons.	40lb. per yard.	Abt double rack.	Minimum, 12½ per cent.; maximum, 25 per cent.	6	100	—	—	Steam locomotive.	Engines by Baldwins, of Philadelphia; cylinders 18in. diameter, 24in. stroke; six driving cogwheels, two being for emergencies.
Catskill Mountains, United States.	1892	1·3	1,630	—	3ft. 0in.	Car complete, 14 tons.	35lb. per yard.	Abt rack, 23lb. per yard, as a safety factor only.	Minimum, 4 per cent.; maximum, 34·4 per per cent.	8	75	—	—	Cable railway, with steam power.	Engine and boiler house at summit; winding drums 12ft. diameter; Abt rack used for safety purposes only. Erected by Otis Elevating Company.
Brienz-Rothhorn, Switzerland.	1892	4·75	5,180	7,388	2ft. 7½in.	Engine, 17 tons; total weight, 26 tons.	40lb. per yard.	Abt double rack, 35lb. per foot.	Maximum, 25 per cent.	4	48	84,000	17,684	Steam locomotive.	Road wheels 1ft. 9in. diameter, run loose on axle; rack wheels 18in. diameter, with 12 teeth; engine cylinders 12in. diameter, 22in. stroke; wheel base 4ft.
Mount Salève, Savoy.	1893	5·59	2,700	3,746	3ft. 3⅜in.	Car body, 4·4 tons; motors and gearing 6 tons; total weight, 14 tons.	30lb. per yard.	Abt single and double rack.	Minimum, 8 per cent.; maximum, 25 per cent.	5	44	92,000	15,660	Electric motor car.	Each car supplied with two 40-h.p. double-reduction motors, running at 600 revolutions, and speed reduced 13 to 1; current supplied by third rail, main lines and rack being used as return.
Burgenstock, Lucerne, Switzerland.	1888	·59	1,443	2,884	3ft. 3⅜in.	Car empty, 4 tons; total weight, 6 tons.	45lb. per yard.	Abt double rack with anchor as a safety factor.	Minimum, 32 per cent.; maximum, 58 per cent.	2·3	40	15,920	25,728	Cable railway, with electric transmission of power — 1,600 volts.	Cable railway; two series-coupled Thury motors, each 60 h.p., at the summit drive the winding drum through gearing having a total reduction of 140 to 1.
Monte Salvatore, Lugano.	1890	1·1	1,972	2,897	3ft. 3⅜in.	Car empty, 4·5 tons; total weight 6·8 tons.	35lb. per yard.	Abt double rack with anchor as a safety factor only.	Minimum, 17 per cent.; maximum, 60 per cent.	2·3	40 standing room for 10 more.	27,610	25,100	Cable railway, with electric transmission of power — 2,000 volts.	Motor station midway up the incline, which is worked in two sections. Oerlikon (Brown) 75-h.p. motor works the winding drums through gearing.
Stanserhorn, Lucerne.	1893	2·5	4,590	6,080	3ft. 3⅜in.	Car empty, 4·5 tons; total weight 6·8 tons.	40·25lb. per yard	No rack.	Minimum, 12 per cent.; maximum, 61 per cent.	2·3	40 standing room for 10 more.	66,750	26,700	Cable railway, with electric transmission of power — 1,600 volts.	Three sections and three motor stations, each having a 40-h.p. Thury motor; current generated at 1,600 volts pressure at the same power station as for Burgenstock.
Wengern Alp, Interlaken.	1893	10·68	—	6,183	2ft. 7½in.	Car empty, 5·07 tons; total weight 8 tons.	41½lb. per yard	Riggenbach's ladder.	Maximum, 20 per cent.	5	48	160,000	14,247	Steam locomotive.	Locomotives of the Abt type; they have two rack wheels, each of 18 teeth.

Digitized by Google

Lanslebourg, Mont Cenis (French slope)	1868	·83	1,150	5,880	4ft. 8½in.	Locomotive, 12 tons; train, 24 tons.	—	Agudio double rack, back to back.	Average 26 per cent.; maximum, 31·8 per cent.	5	—	—	40,000	Wire-rope locomotor.	Rope travels, at 23 miles per hour, by side of rack. Rack made out of flat steel bar, crimped to form teeth while hot. Section of bar, 4⅜in. by ½in.
Lauterbrunnen to Grutsch, Bernese Oberland.	1890	·75	2,214	4,887	3ft. 3⅜in	Car, 7·8 tons; passengers and luggage, 3 tons.	40·3lb.	Riggenbach ladder as safety factor only.	Minimum, 42 per cent.; maximum, 60 per cent.	3	30 standing room for 10 more.			Ballast water system, with wire cable.	Stress in cable is equalised by allowing water in descending car to gradually run out into concrete channel in permanent way.
Grutsch to Murren, Bernese Oberland.	1891	2·7	492	5,350	3ft. 3⅜in.	Locomotive, 7·2 tons; passengers and luggage, 3·5 tons.	35lb.	Riggenbach ladder as safety factor only.	Minimum, 3 per cent.; maximum, 5 per cent.	7	40	18,624	60,000	Electric locomotive, overhead trolley.	Two 30-h.p. motors to each car; current generated at 600 volts by dynamo driven by turbine.
Barmen, Rhenish Prussia.	1894	2·0	550	—	3ft. 3⅜in.	—	35 lb. grooved tram rails in streets.	Riggenbach ladder.	Minimum, 14 per cent.; maximum, 18·5 per cent.	4½	28 standing room for 8 more.	—	—	Electric motor car; two oblong metal frames collect from overhead wire.	Eight motor cars; each car has two axles carrying toothed wheels, and revolved by two 36-h.p. Siemens-Halske motors, 500 volts.

THE SELECT COMMITTEE ON TELEPHONY.

The Select Committee of the House of Commons on the Telephone Service on Friday had under cross-examination **Mr. J. S. Forbes**, chairman of the National Telephone Company. In order to test the allegation that the service was inefficient by reason of delays, he put in a statement of local messages, exclusive of trunk messages, for one day (April 3, 1895) passing through the exchanges at Glasgow, Aberdeen, and Edinburgh. It showed that in Glasgow, out of 69,406 messages dealt with, 59,020 occupied less than half a minute in placing subscribers in effective communication; in 2,694 cases five minutes and over were occupied, the reasons for delay given being that the subscribers did not answer quickly or the junction lines being engaged. Broadly speaking, similar results were brought out in Aberdeen and Edinburgh. At the London Queen Victoria-street exchange, the number of messages dealt with by one operator in charge of 50 subscribers during seven hours on the same day was 508, of which 176 occupied under half a minute, 146 under one minute, 116 two minutes. He put in a return of local messages through the more important exchanges on the company's system, from which it appeared that in the Lime-street exchange, London, there were 2,135 subscribers, the number of local messages per day, including Sundays, and exclusive of trunk messages, being 22,625, and the cost to subscribers per message was 1·04d. In Liverpool there were 3,938 subscribers, the number of local messages per day was 96,644, and the cost to subscribers per message ·25d. In Manchester there were 2,962 subscribers, and 70,952 local messages per day, and the cost to subscribers per message ·27d. The telephone was therefore very much less used in London than in Liverpool or Manchester. In London it did not appear to be so much an essential of the commercial machine.

Mr. Benn: Is that not because in London the charge is higher? No; the greater the business, the more the instrument is worked to its full capacity, the less the charge.

The **Chairman**: And probably the more effective the telegraph service, the less demand for the telephone service?—It is a problem for this committee why it is that London compares so unfavourably with the great provincial towns.

Mr. Benn: May it not be because in London the system is inefficient?—I have not contended that ours is the perfection of service. No doubt people are irritated by what appears sometimes to be unusual delay. They wait for a second or two, and they think it must be a minute. In Germany, with all their perfection, people have to take their turn. They are disciplined to wait; we are not. He continued that, notwithstanding defects, the service was growing, and as evidence of its growth he mentioned that in the United Kingdom the number of new subscribers to the company's system during the year ending December, 1894, was 12,502, the number who had ceased to be subscribers being 4,410; while in London the numbers of new and ceased subscribers were respectively 1,596 and 806. He discussed the question whether it was better to have one uniform moderate tariff over an extensive area or a series of concentric circles, with varying rates for each half-mile or other fraction of a mile, and gave his opinion that the latter course was possible, but extremely inconvenient, and he put in a return to show that it was not popular in London. This return showed the number of subscribers on the metropolitan exchanges having a limited local service and the number on the same exchanges having full metropolitan service. The local service includes free speaking between Sydenham, Bromley, Redhill, Epsom, and Streatham. The number of subscribers to the local service was—in Croydon, 61; Kensington, 3; Kingston, including Richmond and Wimbledon, 2; Battersea, 1; and eastern, 3. The numbers of subscribers having full metropolitan service, on the other hand, were, in the same exchanges, 250, 342, 36, 67, and 279 respectively. The number of private houses connected in the Metropolis was 492. Uniformity, combined with moderation, was the policy which the company pursued. The witness also put in a return of the number of lines and population in various centres as at December last, which, he said, showed that at these particular centres the rates of the National Telephone Company bore favourable comparison with similar places in America, and that they had not made such a poor advance in the development of the telephone in this country as was sometimes asserted.

On Tuesday, Mr. Arnold Morley presiding, Mr. J. S. Forbes, chairman of the National Telephone Company, was further cross-examined.

Replying to **Sir C. Cameron**, the **Witness** gave information as to the terms on which different companies had been bought up by the National Company. The construction capital of these companies was £1,813,000, and the purchase value £3,105,000. The amount of what some people called watered value—though, he remarked, there was a good deal of "spirit" in it—was £1,292,000.

In reply to **Sir J. Fergusson**, he estimated that in London the metallic-circuit system would be completed by the end of the year. Manchester was undergoing the same transformation, and Glasgow was being arranged for. Within the year he thought that, if they received the necessary facilities, they would be able to complete the lines so as to fulfil the engagements they had entered upon.

Questioned by **Mr. Tully**, he said that if cheap rates were to be brought about by municipalities it meant that merchants, manufacturers, financiers, and other people who used the telephone could well afford to pay a great deal more than they did pay, for the users were to be relieved at the expense of the general good.

In answer to **Mr. Snape**, he further stated that every man in England could use the telephone for 6d. a day, and, therefore, he did not think it was beyond the resources of the class of shopkeepers and small tradesmen if they required it.

Mr. A. C. Morton, M.P., put in a statement on behalf of the City Commissioners of Sewers, to show that there was considerable dissatisfaction on the part of telephone users in the City with regard to the service of the National Telephone Company.—*The Times.*

LEGAL INTELLIGENCE.

MUIRHEAD v. THE NATIONAL ELECTRIC SUPPLY COMPANY, LIMITED.

This was an action by Mr. John Muirhead, a former director of the National Electric Supply Company, Limited, to recover £300,

Digitized by Google

being the sum due for director's fees incurred between 1891 and 1894. By the articles of association it was provided that the remuneration of the board of directors should be £200 per annum to the chairman and £100 per annum to each of the other directors. The memorandum of association provided that there should first be set aside out of the net profits of the company such percentage thereof as should from time to time be appropriated by the articles of association to payment of directors' remuneration. Mr. Muirhead was an ordinary director. No net profits had, in fact, been made by the defendant company.

Mr. McCall, Q.C., and **Mr. Clauson**, for the plaintiff, argued that the fees were payable although no profits had been made. "*Re* Lundy Granite Company, Harvey Lewis's Case" (26 L.T., 673; "Isaac's Case" (1892, 2 Ch., 158).

Mr. J. Eldon Bankes, for the defendants, argued that upon the construction of the memorandum and articles in question when read together the agreement between the company and the directors was that the fees should be payable only out of profits

Mr. Justice Day, on Friday last, gave judgment for the defendant company, holding that Harvey Lewis's case (*ubi sup.*) was decided upon grounds not applicable to the present case, and that upon the construction of the memorandum and articles of the defendant company the directors' fees were not payable except out of profits, and that, there being admittedly no profits, the plaintiff's claim failed. His lordship granted a stay of execution for seven days, and directed that the £300, which had been paid into Court under the Master's order, should remain there pending an appeal.

FOWLER v. THE CHELSEA ELECTRIC SUPPLY COMPANY—SANDON v. THE CHELSEA ELECTRIC SUPPLY COMPANY.

The first of these actions (heard before Mr. Justice North on Friday last) was by the tenant of a flat at the mansion, 75, Cadogan-gardens. The second was brought by the landlord and tenants of other flats in the house. In both actions it was sought to restrain the defendant company from continuing an alleged nuisance occasioned by noise and vibration. The actions were brought on on motions for interlocutory injunctions. It was arranged in each case that the motion should stand till trial, the writs being treated as statements of claim, the defendants to put in statements of defence within a fortnight, and leave being given to apply to have the trials expedited.

Mr. Swinfen Eady, Q.C., with Mr. Rowden, and Mr. Samuel Hall, Q.C., with Mr. Badcock, were for the respective plaintiffs; Mr. C. A. Cripps, Q.C., Mr. Vernon Smith, Q C, and Lord Robert Cecil for the defendants.

COMPANIES' MEETINGS.

HASTINGS AND ST. LEONARDS ELECTRIC LIGHT COMPANY, LIMITED.

The annual general meeting of this Company was held at Hastings on Thursday last week, Mr. F. A. Langham occupying the chair.

The report, which was taken as read, was as follows: "The directors present to the shareholders the annexed accounts for the past year, duly audited by the Board of Trade, in accordance with the provisional order. The past year has been an eventful one in the history of the Company, and although, for reasons easily to be explained, the directors are unable to declare a dividend, they consider the Company to be in a sound financial position, the amount earned having been £6,641, as against £5,390 in 1894. It will be seen that large outlay has been incurred in the purchase of additional premises, as well as for new machinery, and arrangements have been completed with the ground landlord whereby the old leases of the four blocks of buildings which now constitute the extensive works of the Company have been surrendered, and a new lease of the whole granted, so that the Company now possess amply sufficient space for a large and increasing business for many years to come. Owing to the change of electric supply from the high-tension direct-current system to the alternating high-tension transformer system, considerable outlay had to be incurred in alterations of consumers' fittings, etc., and this outlay had to be charged to the revenue account. This, however, was exceptional, and will not again occur. A large sum had also to be expended on the public lighting, from which income has only been received since 1st July last. The directors, finding that the installation work was not remunerative, have abandoned it, and sold the stock in-trade, and for the future intend to devote their efforts to the supply of the light only, and they trust that arrangements (now under consideration) will be shortly made whereby a large reduction in the cost of the light can be made to large consumers, not only without detriment to, but to the improvement of, the income of the Company. Messrs. H. M. Baker and G. Roddis retire from the directorate by rotation, but they are eligible, and offer themselves for re-election. The auditors, Messrs. Hart Bros., Tibbetts, and Co., also retire, and offer themselves for re-election."

The **Chairman** moved the adoption of the report, and **Mr. Tyrrell** seconded the motion, which, after some discussion, was adopted.

Mr. Roddis was re-elected a director, and Mr. A. L. Ward was appointed a director in the place of Mr. Baker, who did not offer himself for re-election.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY, LIMITED.

The twenty-ninth ordinary general meeting of this Company was held last week at the Cannon-street Hotel, Mr. W. S. Andrews occupying the chair.

The **Chairman**, in moving the adoption of the report and accounts, said the receipts for the half-year had amounted to £82,815, against £80,338. There was a small increase in the international words exchanged—namely, about 14 per cent.—but a decrease of 18 per cent. in the words exchanged internally; still, notwithstanding that decrease in the words exchanged in Brazil itself, there was a small augmentation in the amount of money derived from that traffic, arising from the circumstances that the messages were conveyed, on an average, a greater distance than in the corresponding period of 1893. The expenses last half-year were £36,403, against £35,592. After deducting £11,601 for debenture interest, and £5,000 for the debenture redemption, there remained £40,059, of which £8,000 had been placed to the reserve fund. The Board now recommended the payment of a dividend of 6s. per share for the half year, making, with the interim dividend 3 per cent. for the year. The item of exchange was the governing factor in their business, and with a satisfactory exchange the Company would be able to give a very gratifying account of its operations. With reference to the litigation with the Brazilian Submarine Company touching this Company's claim of £6,000 a year, and the question of the control of the tariff, which the Brazilian Submarine Company had claimed, the whole matter had been decided in their favour, with costs. As the shareholders were aware, the Government had given notice to acquire the Company's lines under the original concession, and the Legislature had passed an Act, which had been duly signed by the President, and had become the law of the country. Negotiations and arbitration would in due time be begun in Brazil, and the shareholders would have to await the outcome with what patience they might. Governments did not, as a rule, move with lightning speed, and it was not likely that a question of this magnitude would prove to be an exception.

The motion was seconded by **Mr. C. W. Earle**, and carried unanimously.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Braila.—Tenders are invited by the municipal authorities of Braila, Roumania, by June 17 (29), for lighting the town by gas and electricity. Security required, 25,000f.

London, E.—The Shoreditch Vestry invite tenders for the wiring of the Town Hall We have already given particulars. Tenders must be sent in by 10 a m. to-day.

Manchester.—Tenders are invited by the Paving, Sewering, and Highways Committee for laying a system of underground telephone pipes, etc. We have already given particulars. Tenders must be sent in by to-day.

Brighton.—Tenders are invited by the Corporation for the preparation, supply, and delivery at Brighton of cast-iron lamp pillars and copper canopies for electric light arc lamps by to-morrow (June 1). We have already given particulars.

Godalming.—The Town Council invite proposals for the installation of the electric light for public and private lighting within the borough. Further particulars may be obtained upon application to Mr. Samuel Welman, borough surveyor, Church-street, Godalming.

Grimsby.—Tenders are invited for the lighting of the public streets for one year, for the Urban Sanitary Authority. Forms of tender, copy of specifications, and any further information may be obtained on application to Mr. Marshall Petree, borough surveyor, Town Hall. Tenders, sealed and endorsed "Tender for Street-Lighting," to be delivered at the town clerk's offices, West St. Mary's-gate, by 5 p.m. on June 7.

London, E.C. - Tenders are invited by the G.P.O. for the purchase of about 35 tons of old copper (wire, plates, etc.), a large quantity of other metals (brass, zinc, iron, and steel), india-rubber-covered wire, mercury deposit, indiarubber, tinfoil, felt, rope, tar barrels, raw hide pieces, etc. A form of tender can be obtained from Mr. Charles E. Stuart, controller of stores, G.P.O., Telegraph-street, E.C. Tenders will be received until Monday, June 17.

Huddersfield. — The Electric Lighting Committee of the Huddersfield Town Council invite tenders for high and low tension cables, and transformers, complete in cast-iron cases, with switches, fuses, and covers, required during the ensuing twelve months. Specifications and form of tender may be obtained on application to Mr. A. B. Mountain, borough electrical engineer, St. Andrew's-road, Huddersfield, to whom tenders are to be sent not later than the 1st June, endorsed "Tenders for Cables and Transformers."

York.—Tenders are invited for the following articles during six months ending December 31, 1895, delivered carriage paid at the stores at York, for the North-Eastern Railway Company: (1) telegraph apparatus; (2) telegraph wire and line stores. Payment for each month's delivery will be made at the end of three clear months, or in cash, less 2½ per cent discount. Forms of tender may be obtained on application to Mr. Graves, Telegraph Department, York, and tenders must be sent to Mr. C. N. Wilkinson,

Digitized by Google

secretary, York, sealed, and marked "Tender for Telegraph Stores," by noon on June 10.

London.—The Secretary of State for War gives notice that purchases for specific quantities of various articles will be made from time to time during the current year. Among them are electrical instruments for submarine mining and telegraph cable and wire. Manufacturers who may be desirous of tendering should apply to Mr. G. Lawson, director of army contracts, War Office, Pall-mall, S.W., by letter, giving at least names of two well-known firms or public bodies who have purchased from them and are in a position to certify as to the quality of their productions. Applications unaccompanied by references will not be noticed. Firms whose names are already on the War Office list need not apply, as forms for tendering will be sent to them in due course.

RESULTS OF TENDERS.

Hanley.—The Corporation have accepted the following tenders: Condenser for electric light station, Messrs. W. H. Allen and Co., £755; boilers, electric light mains, etc., Messrs. H. and T. Danks, Oldbury, £1,060.

Cardiff.—The following tenders have been received for bottling stores, extension of brewery and electric lighting, County Brewery, Cardiff, for Messrs. William Hancock and Co., Limited. Messrs. J. P. Jones, Richards and Budgen, and C. Jones are the joint architects:

Stephens, Bastow, and Co., Limited, Bristol	£13 250
Knox and Wells, Cardiff	13,105
H. Davies, Cardiff	12,987
J. Allan, Cardiff	12,947
Lattey and Co., Cardiff	12,898
E. Turner and Sons, Cardiff (accepted)	12,648
A. Berridge, Cardiff	12,458

BUSINESS NOTES.

Western and Brazilian Telegraph Company.—For the past week the receipts were £2,712.

Leigh.—The Council's Electric Lighting Bill has been ordered to be reported to the House of Commons.

Snowdon Mountain Tramroad and Hotels Company, Limited. The subscription list closed on Wednesday.

Llandudno.—The District Council's Electric Lighting Bill has been ordered to be reported to the House of Commons.

Brazilian Submarine Telegraph Company.—The directors have declared a quarterly interim dividend of 3s. per share payable on June 22.

Hastings.—Mr. W. J. Lester has completed the erection of a chimney stack, 156ft. high, in connection with the local electric light company's station.

Rio de Janeiro.—News dated 4th inst. from Rio states that the electric light was inaugurated in the locomotive shops of the Central Railway the previous day.

Pontypool.—The Electric Lighting Bill of the Pontypool Electric Light and Power Company has been ordered by Mr. Mellor to be reported for third reading.

Alderley Edge.—The Electric Lighting Bill of the Council has come before Mr. Mellor as an unopposed measure. The Bill has been ordered to be reported to the House of Commons.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 26th inst. amounted to £1 135, as compared with £874 in the corresponding week of last year.

Carlisle.—The Bill embodying the provisional electric lighting order granted by the Board of Trade has been ordered to be reported for the third reading in the House of Commons.

Radcliffe.—A Bill to confirm the provisional electric lighting order has come before Mr. Mellor, chairman of Ways and Means, in the House of Commons. The Bill has been ordered to be reported to the House.

Storage Batteries.—We have received from the newly formed D. P. Battery Company, Limited, 66, Victoria-street, Westminster, a price-list of the well-known "D. P." storage batteries, which have been largely used in the United Kingdom for the past six years.

Harrow.—The District Council have received a letter from the Board of Trade forwarding a copy of revised regulations governing the supply of electric light, and asking for the Council's observations if they desired to make any. No action was considered necessary.

Barnet.—A meeting of the Urban District Council has been held. Messrs. Vaughan and Brown, of Kirby-street, E.C., wrote asking permission to put before the Council a well-prepared proposal for carrying into effect the provisional order *re* electric lighting. The letter was referred to a committee.

Isle of Man.—The electric railway to the summit of Snaefell Mountain is being rapidly proceeded with, and is expected to be ready for July. The overhead system will be adopted and when completed there will be a complete stretch from Douglas to Laxey thence to Snaefell, of about 10 miles.

Harrington Electric Light Company, Limited.—This Company has been registered, with a capital of £3,000, to enter into an agreement, made May 10, with William A. Whiteley, and to carry on at Long Eaton, Derbyshire, the business of an electric light and power company in all its branches.

Agricultural Hall.—The private electrical installation of incandescent lamps for the Royal Military Tournament at the Agricultural Hall, Islington, is being supplied from direct-coupled gas-engines of the Dawson Gas-Engines Syndicate's high-speed type, running at a speed of 660 revolutions per minute.

Liverpool.—A meeting of the Special Lighting Committee of the Corporation was held on Monday, at which it was reported that the draft agreement for the purchase by the Corporation of the Liverpool Electric Supply Company's undertaking was still under the consideration of the directors of the company.

Clifton.—A meeting of the parishioners has been held to consider the question of the proposed renovation of St. John's Church, Clifton. The vicar, the Rev. A. C. C. Anstey, who presided, stated that the matter of electric lighting had been introduced, but that seemed to drop, as they had not sufficient information about it.

City and South London Railway.—The returns for the week ended May 26 were £884, compared with £931 for the corresponding period of 1894, being a decrease of £47. The total receipts for the current period of the present half-year are £19,604 against £19,144 in the corresponding period of 1894, an increase of £460.

Chester.—A meeting of the Electric Lighting Committee has been held, at which it was resolved to recommend the Council to accept the contract of Messrs. Parker, Limited of Wolverhampton, to provide the city with an installation of the electric light. If the Council approve of the recommendation, the work will be proceeded with without delay.

Telephone Catalogue.—We have received from the Electrical Company, Limited, 122, Charing Cross-road, an illustrated catalogue of their telephones. Among the sets dealt with are the students' telephone, without bell; the domestic telephone set, with bell; micro-telephones, with and without bell; desk set; portable set, with hand microphone and bell; and magneto-induction sets.

Hanley.—The Town Council have held a meeting, at which the Electric Lighting Sub-Committee recommended the acceptance of the tender, amounting to £755, of Messrs. W. H. Allen, Sons, and Co., for the supply of a condenser required at the electricity works. Mr. Cottam, electrical engineer, tendered his resignation, having obtained an appointment at Hampstead, and this the sub-committee accepted.

The Telephone in Aberdeen.—The National Telephone Company has 1,029 subscribers in Aberdeen, and 866 exchange subscribers. On 3rd inst. the number of local messages was 15,054, and in more than 14 out of every 15 cases effective communication occupied less than half a minute. At the central exchange the average daily number of local messages in the counting week in March was 11,996, or 14 per subscriber, the mean cost for each message being ·37d.

Nottingham.—We understand that, although, as is natural in this bright weather, the demand is somewhat slack now, since the public supply was commenced at Nottingham there have not been a single cause of failure. There have been no complaints, and the current has been supplied uninterruptedly from that time to the present. The accounts show that the income, after allowing for interest and repayment of loan, is within a couple of hundred pounds in the half-year of a complete balance.

Great Northern and City Railway.—The Unopposed Bill Committee of the House of Commons on Tuesday passed the Bill which gives to the Great Northern and City Railway Company an extension of time until 1900 within which to construct their authorised electric railway from the Canonbury branch of the Great Northern Railway, near Finsbury Park, to the City. The attempt to change the motive power from electricity to steam proved unsuccessful, in consequence of the Standing Orders Committee refusing to dispense with the necessary orders.

New Mains.—The Highways Committee of the London County Council reported on Tuesday that they had considered a notice from the County of London and Brush Provincial Electric Lighting Company, under the Wandsworth Order, of intention to lay mains in Tooting High-street, Balham road and hill, Clapham Common, High street, Pavement and Old Town, Streatham Hill, High road and common, Upper Richmond-road, Kingston-road, East Hill, Trinity-road, Putney Hill, and High-street; with 48 crossings at various places. The details supplied by the company are insufficient, and until further information shall have been supplied, the committee think the Council should withhold its sanction to the works. They therefore recommended that the Council do formally disapprove the works referred to in the notice.

Newcastle-on-Tyne.—There is to be no buying up of existing electric light companies on the part of the Newcastle Corporation. The Electric Light Committee have carefully considered Prof. Kennedy's recent report, and have come to the conclusion that they cannot recommend the Council to purchase existing rights. While they have taken this action, however, the members of the committee have not abandoned the idea of a corporate electric light supply. The town clerk of Newcastle has been instructed to make enquiries on the matter, and the committee will afterwards consider the advisability of getting the Council to apply for powers to provide an independent supply. They pay something like £14,000 per annum to the gas company alone for lighting, and this in itself, it is contended, would furnish a large return for money expended to begin with

Edinburgh.—The Free Assembly Hall is the first of the large halls in Edinburgh to be lighted by electricity. The current has

Digitized by Google

been obtained from the Corporation service lines in the Lawn-market, and the installation has been completed by Messrs. Smith and Co., electrical engineers, George-street. It is on the three wire system, and provides seven switches—six of which control the lights in the hall and one the corridor lamps. The roof is studded with 40 incandescent lamps, of which 12 are 50 c.p., 18 32 c.p., and 10 are 16 c.p. At a meeting of the Electric Light Committee of the Town Council a requisition was received from inhabitants of the Stockbridge district requesting an extension of the electric light for private purposes to the Water of Leith Bridge. The necessary guarantee being forthcoming, the committee resolved on the extension, which will cost about £1,200.

Oriental Electric Light Company.—"We," says the *Bangalore Daily Post*, "are much pleased to see the very energetic and successful efforts on the part of Mr. Simpson in the Bangalore business, in obtaining the high patronage of the British resident of Mysore for lighting the residency with the electric light, and this would alone lead, we are sure, to the lighting of the several most important places in Bangalore shortly. We are glad to know from the papers before us that the Company are about to establish an agency in Madras and Ooty, under Mr. Simpson's management, and we are almost certain that this will be a success. We learn from the credentials from Messrs. William Watson and Co., bankers and agents, Bombay and London, that Mr. Simpson is directly connected with the Company in London and is also a partner, and has the entire working and management of the Company's business in India under their direction."

Ayr.—A meeting of the Town Council has been held, when it appeared from a minute of the Electric Lighting Committee of May 23 that the Board of Trade had given their provisional approval of the system for the supply of energy subject to certain regulations and conditions for securing the safety of the public, and for ensuring a proper and sufficient supply of energy. The clerk submitted a communication from the Board of Trade, dated 10th inst., anent a revision of the regulations, and the meeting remitted them to Mr. Hammond, who intimated that he had been charged by several other corporations to report regarding them, and that he intended submitting one report to the Board and to send a copy thereof to each corporation. The clerk was instructed to point out to the Board the recent approval of the present regulations. The Council also decided to extend the electric mains round by Miller-road and Alloway-place while the present contractors are at work.

Telephone Transmitters.—In the year 1878, the late Rev. Henry Hunnings, curate of Bolton Percy, near York, accidentally discovered the wonderful effects produced in a closed battery circuit by a small quantity of loose granulated carbon between conductors, and upon these effects the "talking" power of the Hunnings' telephone transmitters depends. Very shortly after his discovery the rev. gentleman brought it to Mr. Cox-Walker, M.I.E.E., then living at York, who gave it his immediate attention. We are informed that although the utility of the transmitters as commercial instruments was denied by leading electricians, Mr. Cox-Walker's faith in them remained unshaken. A patent was obtained, and, after much experimenting and many disappointments, he and Mr. Hunnings succeeded in making powerful and reliable transmitters, and Mr. Cox-Walker established a factory in Darlington for their manufacture and sale in conjunction with a new telephone receiver of exceptional power, which he had also then invented. Messrs. Cox-Walkers, electricians, of Darlington, have made great improvements in the transmitters recently, and are manufacturing large numbers for all parts.

Coventry.—A meeting of the Town Council has been held, at which Mr. West said at the last meeting of the Council the members were anxious to get all information available as to the Electric Light Committee and their doings. It was seen by the committee's report that it was proposed to extend the mains along Warwick-road, several residents near the chapel being anxious to be supplied with the light. He had no doubt that possibly the Reform Club might see the necessity of having a little more light themselves. Respecting the water-main in Sandy-lane, that was a precautionary measure. When the canal was emptied, it would be necessary to get water from somewhere for condensing purposes. Mr. Hammond, the engineer, had been to Leeds and inspected the plant. He found it in a very forward state, and if necessary the whole of it might be delivered in Coventry three weeks hence. The engineer hoped that the light could be supplied to the citizens in about three months from the present. Mr. Ram told him that the roadway was up that day for putting in the transformers, etc., positively for the last time. The minutes of the Electric Light Committee were then confirmed.

Electric Railway from Derby to Ashbourne.—The Derby *Daily Telegraph* states that a scheme for the construction of an electric railway from Derby to Ashbourne is in contemplation. At present, as visitors to the interesting little town on the banks of the Dove are often painfully aware, it is dependent solely in the matter of railway accommodation on the North Staffordshire Company, by whose roundabout route the journey occupies three times as long as would be the case by a direct service. Mr. John Shaw, jun., acting for some local gentlemen, has been engaged for some time past in working up the scheme, and we understand that the negotiations are so far advanced that the details will be placed before the public during the next few weeks. The route which it is proposed to take will follow pretty closely the course of the present highway through Kirk Langley and Brailsford. A direct railway between the two towns is no new project, the last attempt of the kind having been made during the mayoralty of the late Sir Abraham Woodiwiss. Now that it has been decided to employ electricity, the scheme will possess additional interest to the engineer, inasmuch as it will be the largest electric railway in the United Kingdom.

Thurmaston.—A meeting of the Urban District Council has been held at which Mr. Lavender attended, on behalf of the Wigston Electric Lighting Company, and submitted an estimate for the lighting by electricity of the village. For the lighting of the streets by arc lights he had made an approximate estimate of £1,000 and the annual cost of working and maintenance he put down at £189. The present cost of gas at 4s. 2d. per thousand was £72. 16s., but on adopting electricity instead of the 240 c.p. which they had at present the electric light would give them 10,500 c.p. The approximate estimate of an installation for private use with incandescent lights was £2,000, and on the basis of 500 lights the annual costs would be £331. He pointed out that the profit of the private supply could be devoted to defraying the cost of the public supply. Mr. Blount thought the matter should be deferred for the present. An expenditure of £3,000 was a rather serious item, and they ought not to embark on such a scheme without the sanction of a town's meeting. They could not reasonably expect people to discard the use of gas until they were certain electricity would be better and cheaper. It was decided to defer the matter for three months.

Bournemouth.—It is stated in a local paper that on Friday morning an accident occurred in an underground chamber, belonging to the Bournemouth Electric Supply Company's system, which is beneath the pavement in Glen Fern-road, Old Christchurch-road, to a man named William Spicer, of Winton. Spicer has been engaged for a considerable time by the company, and thoroughly understands the work in which he was on Friday engaged. A new transformer had been lowered into the chamber, and the accident happened during the handling of the cables the current not having been turned out of the circuit as is customary in such a case. Spicer received a number of successive shocks, which for a time prostrated him. His shouts were heard by many persons in the neighbourhood of the transformer, and one of his fellow-workmen, in trying to lift Spicer, himself received several shocks and was obliged to relinquish his hold. After a short time, however, Spicer was moved from immediate contact with the cable, and with the aid of ropes was lifted to the surface of the roadway. His boots were removed, and it was found that his feet and hands were blistered. He was removed to his home and attended by doctors, but was found to have sustained no very serious injury.

Appointments.—The Victoria Institute Committee of the Worcester Corporation intend to appoint a science master of the institute. Salary £200 per annum. The person appointed will be required to give the whole of his time to his duties. The work of the institute will include that of organised science day and night schools, and other day classes, as well as evening classes in technology and commercial subjects. The appointment will date from July 31. Applications, stating age, subjects in which qualified, and teaching experience, together with three testimonials of recent date, must be delivered by June 4, addressed to the Secretary, Victoria Institute, Worcester.—The Liverpool Salvage Association require a practical engineer to act as superintendent in charge of steam pumps, engines of wrecking steamers, and incidental wrecking machinery including electric installations, etc., to take charge of the working of same, and to do any other work which may be required. Salary £150 to £200, with extra allowance if employed on special or foreign service. Applications, stating age and experience, and enclosing copies of testimonials, must be addressed by June 10 to the Chairman, Liverpool Salvage Association, A 20, Exchange-buildings, Liverpool, and endorsed "Application for Engineer."—The Walsall Corporation want a fitter at £2 2s. at week to attend to the engines, boilers, pumps, and dynamos at their central electric light station, and a competent man as battery man and jointer at £1. 15s. a week.

Islington.—A meeting of the Vestry has been held, at which a report was received from the Public Health Committee, stating that it has had under consideration the drainage of 3 Burnard-place, which is the property of the Vestry, and which has been redrained without an inspection-chamber being constructed, as required by the regulations of the Vestry; and that as the attention of the Electric Lighting Committee has been drawn to the matter without effect, it recommends that the Electric Lighting Committee be instructed to comply with the regulations of the Vestry. Mr. Ansell moved the adoption of the report. Mr. Lambert said the Electric Lighting Committee had had no quarrel with the Public Health Committee. The drainage of the house was wrong, and Mr. Barber, the surveyor, was called in, and he said it must be reconstructed. The house was placed in a sanitary condition. The Electric Lighting Committee considered that the chamber was unnecessary. If the Vestry insisted that the chamber should be constructed, it would be done, but he declared it was a wilful waste of public money. The houses would be pulled down in less than two years, and upon the site the electric lighting works would be extended. Recently a sum of £20 had been expended upon them, and the rental was 10s. a week. Mr. Dryden said the Electric Lighting Committee had not a leg to stand upon. Were the Vestry going to decline to do that which they compelled private owners to do? After some discussion, the report was adopted.

Strand.—A meeting of the Strand Board of Works has been held, at which a prolonged and occasionally somewhat heated discussion took place on a report of the Joint Works, Wharf, and Lighting Committees dealing exhaustively with the subject of the supply of electricity for lighting the Strand. More than a year ago the Charing Cross Electricity Supply Corporation made an application for a provisional order to supply the Strand district with electric light. That application was not favourably enter-

Digitized by Google

tained, but that of a competing company—the Metropolitan Electric Supply—which offered better and cheaper terms, met with more favour. The subject has been debated in committee and at the ordinary meetings of the Board for the last 12 months, the view generally taken being that there should be, in this matter of electric lighting, effective competition for the whole district The joint committees, having given a long history of the negotiations with the two companies concerned, now recommended that it was not desirable, in consequence of the constant and extensive interference with the streets and foot pavements, of which the Strand tradesmen and shopkeepers complained as being injurious to their business, to support the application of the Charing Cross Company for a provisional order. and that a petition to Parliament in opposition to the company's Bill be lodged. The opinion of the Board seemed about equally divided as to the expediency of adopting the committee's report and rescinding former resolutions in favour of the Charing Cross Company's application. In the result the report was referred back to the committee for further consideration.

Empire of India Exhibition.—The arc lighting of this exhibition at Earl's Court is carried out by means of six of the latest type of Brush series dynamos each designed for 55 lights at 800 revolutions, and the regulation is effected by Brush-Geipel regulators of the most recent water-resistance pattern. The incandescent lighting plant consists of Mordey alternators of the new type, having a joint capacity of 350 kilowatts, which embody all the latest improvements. Two of the alternators have an output of 100 kilowatts each, and run at 325 revolutions with a periodicity of 130; they are coupled to the engines by means of Raworth's patent flexible couplings. There are also two 75-kilowatt alternators running at 355 revolutions and with a periodicity of 130; one of these is direct coupled to its engine, and the other driven by belt. The exciting plant is in triplicate; there is a direct-coupled exciter on each of the alternators, and, in addition, two 25-kilowatt 105-volt compound-wound machines of the Brush-Vienna type, driven by belts off separate engines. The alternator and exciter boards consist of marble panels with the usual Brush Company's switches and instruments. They are also fitted with double-pole change-over switches for throwing either of the alternator fields on to the common exciter omnibus bars, or for connecting each alternator to its own independent and direct-driven exciter. The arc-lighting board is arranged for six dynamos and five circuits, with hook and stirrup pattern switches. The transformers are of the Mordey-Victoria type, having a joint capacity of 276 kilowatts, the majority having an output of 12 kilowatts. All are provided with earth shields between primary and secondary.

St. Pancras.—The Vestry have held a meeting at which Mr. John Hunt called attention to the decision of the Vestry to construct an electric sub-station in St. Andrew's Gardens, Gray's-inn-road, and raised the question whether the provisions of the Metropolitan Open Spaces Act, 1881, did not prevent the Vestry from taking this course. He moved that the Parliamentary Committee be instructed to report on the matter. Mr. Squibb seconded the motion, which was supported by Mr. Clements. Dr. Smith considered that as the piece of ground in question had been purchased under the Metropolis Local Management Act, and had never been used for interments, the Act which Mr. Hunt had quoted did not apply at all in the case. Mr. Hunt's motion was defeated. The decision of the London County Council to lend £14,300 for 42 years, on the condition that no further loan should be raised by the Vestry during the currency of that period for the replacement or renewal of any works included in the loan, was again the subject of discussion. Mr. Clements considered that the rate of interest, 3¼ per cent., charged by the Council, was too high, and that as money was so cheap it ought to be borrowed at 3 per cent. He moved that the Finance Committee be empowered to negotiate with the Vestry's bankers with a view to raising a loan by the public issue of bonds in the City at 3 per cent. interest. Mr. Towner seconded the motion, which was lost. Mr. Towner asked whether the Electricity Committee was aware that some of the ventilators were placed in dangerous positions. He referred especially to one at the corner of Mornington-crescent and High-street, Camden Town. Mr. Sweet was of opinion that the ventilator in question was not at all dangerous. The committee had, however, instructed their engineer to view all the ventilators. On Tuesday the London County Council decided to draw a cheque for £14,300 for a loan to the St. Pancras Vestry for electric lighting purposes.

Dover.—A meeting of the Town Council has been held at which a letter was read from the electric lighting company, asking that a small committee of the Council should meet Mr. Bagshawe to arrange the quantity of light which should be supplied to the Town Hall on different occasions, the quantity varying in the various cases for which the hall was required. Councillor Mackenzie thought the old Electric Light Committee should be appointed He did not think there should be an extra charge for the electric light. He moved that a committee consisting of Alderman Pepper, Councillors Thorpe and M. Mowll be appointed. Councillor G. Fry suggested that the committee should settle the matter themselves without any assistance from the Electric Lighting Committee. He supposed there was such a thing as a meter, and they could settle it by that. Alderman Pepper supported the request of the electric lighting company. He pointed out that it would be extravagant to light the whole of the lamps (240), and it was necessary that they should have some information in deciding which should be alight. The Mayor pointed out they had spent £600 on the electric light fittings in the Town Hall, and practically at the present time they did not use them. The charges wanted putting on a proper basis—he did not care what sort of a committee did it, but something should be done. Alderman Peake said the lighting of the hall by gas cost 10s. per night, and it could easily be ascertained what the electric light would cost, as they knew the power of the lamps. He thought there should be a charge for the hall, with the extra charge for lighting by gas and also by electricity. On Alderman Pepper's motion the old Electric Light Committee was appointed, with the substitution of Councillor Chitty for Councillor Brown. An amendment that the committee should consist of the whole Council was moved by Councillor Edwin, but was not seconded, and fell through.

Derry.—A meeting of the Lighting Committee of the Corporation has been held, at which the following report from Mr. Christie, resident engineer, was read: "With the sanction of the Mayor and chairman of the Lighting Committee, I have during the past fortnight had the Guildhall clock lighted each evening by electricity, a temporary connection being made to one of the city mains. I feel sure that if I had more suitable lamps specially made with proper reflectors and connections underground to two currents I could almost entirely overcome all the objections which at present exist with this temporary arrangement—viz, the dark shadow on the lower half of the dials, the clock being in darkness after midnight on alternate nights, and the inconvenient overhead connection from the top of the lamp to the tower window. To light up the clock properly with all the gear complete would cost about £70, as the same connections off the street mains, without any addition, would do for lighting the main hall of the Guildhall I give you the figures for it also at about £80. This would be for four ornamental 2,000-c.p. arc lamps, and would include all the necessary gear for raising and lowering, etc. From Mr. Algeo I find that the annual gas bill for lighting the clock comes to about £70, and the receipts for lighting the Guildhall by gas to some £40 more making a total of about £110 a year, so that for little more than one year's gas bill the necessary plant could be bought outright, whilst the annual cost of upkeep, carbons, etc., would scarcely be felt. The way in which I purpose to put it down, having half the lamps on different circuits, would reduce the chances of failure at any time to a minimum. If you consider the scheme worthy of adoption, it would be well to have it carried out during the summer, as I could then do the work, at odd times, with my own staff without employing any outside assistance. If you desired to light the staircase and corridor by means of two extra arc lamps, the additional cost would be about £30." The report was approved of.

Brighton.—We have previously referred to the error in tendering in connection with the mains required by the Corporation. At last week's meeting of the Town Council, the Lighting Committee submitted a special report to the effect that since the meeting of the Council on the 16th inst., at which the tender of the British Insulated Wire Company for the supply of vulcanised rubber and lead covered and armoured cables for the electricity undertaking was accepted, they had received a communication from the company stating that they had made a mistake in their tender, and asking permission to withdraw their offer for the supply of the cables The committee recommended that the British Insulated Wire Company be allowed to withdraw from the contract, and that the tender of Messrs. Siemens Bros. and Co., Limited (which is the next lowest), be accepted at £289 per mile for three-core cable and £239 per mile for two-core cable. Alderman Moon moved the adoption of this report. He stated that the tender of the British Insulated Wire Company amounted to £230 per mile for three-core cable and £215 per mile for two-core cable, and the difference between their tender and the one which the committee now proposed for acceptance would result in a loss to the Corporation of between £300 and £400 But previous to the company being informed of the acceptance of their tender by the Corporation they wrote to the town clerk to the effect that some mistake had arisen with regard to the thickness of the indiarubber coating of the wires owing to the manner in which the word "radial" had been employed in the specification as defining the thickness of the indiarubber. The effect of the error was that the tender was based on a thickness of $\frac{1}{16}$in. instead of $\frac{1}{8}$in.; and though he (Alderman Moon) thought the clause in the specification clear enough, still, as it was possible to interpret it in the way in which it was stated the company had done, it was felt by the committee they had nothing to do but to release them from the tender. Councillor Berry seconded; and Alderman Moon having assured Councillor Dell of Messrs Siemens's willingness to adhere to their tender, the motion was carried, and the meeting terminated.

Lynn.—A meeting of the Town Council has been held at which the subject of the electric light was brought forward. Mr. Jermyn had, according to the agenda, given notice to move that application should be made for a provisional order for electric lighting. He said this was not exactly what he intended it to be, or sent to the town clerk. He did not bring up that question with the idea of spending any money for new works at the present time, and he had not introduced the resolution with any desire to prefer an attack on the gas company. As far as the gas company were concerned they had always treated him, as a large consumer, with every consideration, but it was a matter that rather affected the town. He did not want a mistake to be made—he spoke of the electric light as the modern light—like the terrible mistake that was made years ago when a private company was allowed to start the gas-works. He did not want a private company to come in and take up what would be a large business, the profits of which should be applied to the borough fund, and of which the ratepayers should have a very large share. He did not know whether the Corporation would take it up, but he would like to approach the Board of Trade for provisional powers during the next three years to put in

Digitized by Google

an installation for electric light. That would prevent any private company from taking any advantage. He did not know exactly how to word his resolution, but if he might alter it he would move that they apply for a provisional order giving them leave within the next three years to carry out such works as would be necessary to put in an installation of electric light. Mr. Woodwark seconded. Mr. Rose said the resolution before the Hall was somewhat nebulous. The Board of Trade would want to know something more. There was no doubt that the electric light would be the light of the future, and sooner or later it would come to King's Lynn. He had an idea that they ought to go ahead now. They had been somewhat twitted about special committees, but he would like to see a special committee appointed to make it their business to go into this matter and answer the questions that had been put, and then if deemed necessary to go into the system at once. There were plenty of people only just waiting to adopt the electric light, and if the thing was coming he did not see why it should not be gone on with as soon as practicable. He would suggest that the matter be either referred to one of the standing committees or a special committee. Mr. Jermyn said, with the permission of his seconder, he would ask that the matter should stand over until the next meeting of the Hall, when the town clerk could give them all the information they wanted on the matter. This course was agreed to.

Hampstead.—At last week's meeting of the Vestry, Mr. Thwaites, chairman of the Lighting Committee, moved the adoption of a recommendation from that committee that a chief assistant electrical engineer be appointed by the Vestry. Mr. J. Aitchison moved, as an amendment, that the appointment be deferred until after the arrival of Mr. G. H. Cottam, who, at the previous meeting, was appointed chief electrical engineer at a salary of £300 per annum. Mr. Richardson seconded the amendment. Mr. Underwood explained that it was necessary to have a chief assistant now that the whole of the work had to be done by the Vestry's own staff without the advice of a consulting engineer. Mr. T. Eustace Smith suggested that the appointment should be made temporarily and not permanently. Mr. Hackworth said that the appointment would in no sense be a permanent one, seeing that the official would be subject to a month's notice at any time. Mr. Reed remarked that when the chief engineer commenced his work the chief assistant engineer would be mainly engaged in outside work. The amendment was defeated. Mr. T. Eustace Smith and Mr. Richardson rose together, and the chairman called on the former. Mr. Smith: I think we both rose for the same purpose. I wish to move as an amendment that the word "temporarily" be inserted before the word "appointed." Chairman: Is it worth while to do so? Is it worth while fighting it all over again when you know that you have the matter in your own hands by giving a month's notice? Mr. Smith: I will withdraw the amendment if that is your view. It was decided that the salary of the assistant should be £200 per annum. Mr. Thwaites then moved that Mr. E. Sayer, at present one of the assistant engineers at the central station, be appointed to the office. Replying to some remarks made during the debate, he said it was true that Mr. Sayer had received the offer of another appointment, but had expressed his desire to remain at Hampstead if his position were improved The Electric Lighting Committee had every confidence in his ability, and had placed him in command of the station until the arrival of the new chief. This motion was carried. The Lighting Committee reported that they had appointed a temporary assistant engineer at the station, at a salary of £2 per week (the appointment being subject to one week's notice), until such time as the chief electrical engineer should take up his duties. This was approved of. The Lighting Committee recommended that the necessary substation, feeder, and distributors for the private lighting of Haverstock-hill, from Belsize-grove to Eton-road, be laid down at an estimated cost of £892, and that a high-tension main for private lighting be laid down from sub-station 6A, in Heath-street, to the corner of Redington-road, at an estimated cost of £294. This recommendation was approved of.

Transformer-Chambers.—The Highways Committee of the London County Council on Tuesday reported that on February 12 last, the Council, in giving sanction to certain of the works referred to in the notice of the House-to-House Electric Light Supply Company, expressly withheld sanction to the construction in Kensington High-street of a transformer-chamber of the inside dimensions of 5ft. by 6ft. 6in., and between 6ft. and 7ft. deep. The company gave notice on May 14 that, as its system of supply had received the provisional approval of the Board of Trade, it intended to proceed with the construction of the transformer-chamber; and by the direction of the committee the Council's solicitor warned the company that as it had not appealed to the Board of Trade it had no authority to proceed with the work. The company has since intimated its intention to appeal; but has also, with the view of meeting the objection of the Council, offered to place the proposed chamber in Wynnstay-gardens, a position which is certainly less objectionable than that first proposed. The Council has consistently objected to the construction of large transformer-chambers under the public thoroughfares, and the committee do not see any reason for an exception being made in this case. They therefore recommended that the House-to-House Electric Light Supply Company be informed that the Council is not prepared to depart from its decision withholding sanction to the construction of the transformer-chamber referred to in the company's notice, dated January 21, 1895, or to sanction the construction of the chamber in the alternative position in Wynnstay-gardens, shown upon the plan submitted with the company's letter, dated May 22, 1895; and that consequently the Council leaves the matter for the decision of the Board of Trade upon appeal. The committee considered a notice from the County of London and Brush Provincial Electric Lighting Company of intention to construct 42 transformer-chambers in St. Luke's and Clerkenwell. The Council has repeatedly expressed its disapproval of the construction of transformer-chambers of large size in the public streets, and that being so, the committee think the Council should refuse its sanction to the construction of the chambers referred to in the notice. They recommended that the Council do formally disapprove the works referred to in the notice. Another notice has also been received from the same company of intention to construct 34 transformer-chambers in the Wandsworth district in the positions shown upon plans submitted with the above-mentioned notice. The Wandsworth District Board entertains with the Council a very strong objection to the use of the public streets for these chambers and following the practice hitherto adopted, the committee think the Council should refuse its sanction. They accordingly recommended that the Council do formally disapprove the works referred to in the notice.

Kingston-on-Thames.—The Lighting Committee resolved to inform the authorities of the several places of worship in the borough that it was proposed to supply electric current to places of worship at 4½d. instead of 6d. per unit, but without discount. The Local Government Board having sanctioned the borrowing of £7,772 for 15 years only for electric lighting, a deputation was appointed to wait upon the Board and urge that the full amount of £10,000 be authorised for 25 years. An application from Messrs. New and Mayne, asking permission to lay a pipe across Portsmouth-road to the river, for the purpose of charging electric launches, was refused, as the committee were themselves making arrangements for charging launches. The committee recommended the Council to accept an offer of Messrs. Siemens to supply and fit up the necessary cable, etc., from the electric works to the river for the purpose of charging launches at about £100. The Town Council have approved of the recommendation. Mr. J. E. Edgcome, A.M.I.M E, the borough electrical engineer, has submitted to the Council the first annual report upon the electric lighting station. The revenue account of the works from October 16, 1893, to December 31, 1894 (the period which the report covers), shows a deficit balance of £1,298. 18s. 7d.; the receipts being £1,985. 19s. 7d. (1,116. 0s. 9d. from private consumers, £41. 9s. rental of meters, and £828. 9s. 10d. for lighting 36 arc lamps at £20 per lamp); and the expenditure £3,284. 18s. 2d. This total is thus made up: generation of electricity, £1,921. 13s. 5d.; distribution of current, £296 11s.; rent and taxes, £46. 9s. 8d.; management expenses, £276. 5s. 1d.; special charges, £743 19s. (which includes £711. 14s. 10d. for repayment of principal and interest, and £32. 4s. 2d. for insurance). The total "works cost" per unit of electricity is 4·15d.; the total plus management expenses is 4 754d; and the total including everything is 6·146d. No capital account is furnished. The number of units supplied during the period of 14 months under notice was—to private consumers 44,642, and to public arc lamps 83,625. The charge per unit to private consumers is 6d.; the charge for the arc lamps is about 2½d. per unit. The report continues: "The amount receivable for the sale of current for the first quarter of 1895, ending March 31, is £469. 18s. 10d. It will be seen, therefore, that the receipts for this quarter are more than double the receipts for the corresponding quarter of 1894. This is a very promising outlook for this year's returns. The lamps at present installed by consumers, including those of Town Hall, Corporation Offices, and free library, are equal to 4,150 lamps of 8 c.p. There are 36 arc lamps installed, each of 2,000 nominal candle-power. When first erected these lamps displaced 90 gas lamps, but by rearranging some of these arc lamps during last summer, the number of public gas lamps displaced by these 36 arcs has been increased to 114, the public electric lighting having been extended along London-road to the foot of Kingston-hill, along Richmond-road to Acre-road, and through Eden-street from Clarence street to St. James's-road, thus completing the belt of light in the centre of the town. As the number of private consumers increases (and assuming that for the present the number of public arc lamps will not be increased) so in proportion will the quantity of units sold at 6d. increase as compared with those sold at 2½d., and this of necessity will considerably raise the average price obtained for current above the present average price of 3·638d. per unit. On the other hand, this increased output will tend to lower the average cost price of 6·146d per unit, the average for last year, as the expenses for a large increase of output will not be proportionately as high. For instance, a very small addition to the wages sheet would be necessary to cope with three to four times the present output, whereas such fixed charges as management, insurance, and taxes, would not in any way be increased. Although fuel would to an extent increase in proportion to the amount of electricity supplied, I see no reason why the present average of 2 025d. per unit for fuel should not be reduced to 1·1d. or 1 2d. per unit sold, or even less, especially if we can obtain customers to use current for cooking, heating, and motor purposes, which will help the day load, at present a very small one, but for which it is necessary to keep machinery running to meet any demand which may arise during the whole of the 24 hours. When in this manner the cost of production shall have fallen and the average price obtained have risen until they are equal, the works will be self-supporting, and beyond that point they will become a profitable and paying manufacturing business, and the profit so obtained could be applied to lowering the ordinary lighting rate upon the borough. The returns of the first year's working show conclusively that the whole question of profit earning in an undertaking of this kind is

Digitized by Google

merely one of sufficient demand. It must be obvious to the ratepayers that the desired result of converting what is at present a burden upon the rates into a profit earning undertaking for the benefit of the borough lies entirely in their own hands, and that such a result will be obtained when the demand for current has sufficiently increased. It must therefore be to the interest of every ratepayer to endeavour to bring about this desired result."

PROVISIONAL PATENTS, 1895.

MAY 20.

9919. **Heating body for electric soldering irons.** Friedrich Wilhelm Schindler-Jenny and Paul Stotz, 89, Chancery-lane, London. (Complete specification.)

9937. **Improvement in the manufacture of active material for secondary batteries.** Siegfried Hammacher, 31, High Holborn, London. (Complete specification.)

9939. **Improvements in or relating to electric railways.** Antoine Léon Robton, jun., 323, High Holborn, London.

9961. **Improvements in connection with laying submarine electric cables.** Charles Scott Snell, Culver Park, Saltash, Cornwall.

9966. **Improvements in or relating to electric arc lamps.** Albert Lewis Davis, 70, Chancery-lane, London.

9967. **Improvements in electric regulators.** Harry Neville Moody, 70, Chancery-lane, London.

9969. **Improvements in dynamo-electric machinery.** Horace Field Parshall and the British Thomson-Houston, Limited, 70, Chancery-lane, London.

MAY 21.

9981. **The application of the motor-generator for purposes of electrolysis.** Alfrest Ernest Old, 66, Stanmore-road, Edgbaston, Birmingham.

9997. **Improvements in the application of electrical energy to the heating of air or other gaseous bodies.** Robert Cattley Jackson, 4, Framlington-place, Newcastle-on-Tyne.

10027. **Improvements in telephonic installations for increasing the strength of the transmitted sounds.** Anton Hamm, Gergely Blank, Victor Brandt, and Gyula Körmendy, 28, Southampton-buildings, Chancery-lane, London.

10029. **Improvements in pendants or electroliers for electric lamps.** John Webb Singer, Walter Herbert Singer, and Edgar Ratcliffe Singer, 40, Chancery-lane, London.

10052. **Improvements in electric railway signals.** Henry Valentine Miller and Alexander Cicero Miller, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

1058. **Improvements in or appertaining to electrically-illuminated advertisements, signs, and like devices.** George Frederick Kenyon, 27, Kirkgate, Bradford.

MAY 22.

10114. **The Galvanopile, an improved form of galvanic battery.** Richard Joseph Crowley, 10, Harbour-row, Queenstown.

10134. **Improved means applicable for use in the decomposition of substances susceptible to electrolytic treatment.** George Gatton Melhuish Hardingham, 191, Fleet-street, London. (Rudolf Langhans, Germany.)

10142. **Improvements in electric gas-lighting devices.** James Tarbotton Armstrong, 45, Southampton-buildings, Chancery-lane, London.

10154. **New or improved electrical attachment for drinking-vessels.** George Gregory Smith, 54, Fleet-street, London.

10155. **Improvements in or relating to telephone systems.** Moise Freudenberg, 45, Southampton-buildings, Chancery-lane, London.

MAY 23.

10241. **A novel construction and arrangement of appliances for generating electricity.** Alfred Launcelot James Tait, and Walter Henry Pearson, 166, Fleet-street, London.

MAY 24.

10249. **Improvements in and connected with multiple switch-boards for metallic circuit.** Hermann Oppenheimer, 55, Redcross-street, London. (Actien Gesellschaft Mix and Genest, Germany.)

10250. **Improvements in or relating to electric bells, signals, and other means of electrical communication.** Thomas Sloper, 11, Brittox, Devizes.

10277. **Improvements in apparatus for measuring electrical currents.** Siemens Bros. and Co., Limited, and Edward Friedrich Hermann Heinrich Lauckert, 28, Southampton-buildings, Chancery-lane, London.

10284. **Improvements in the manufacture of incandescent or glow lamps.** Charles John Peach Robertson, 6, Bream's-buildings, Chancery-lane, London.

10308. **An improved electric lock.** Louis Defert, 40, Chancery-lane, London.

10302. **Improvements in connection with laying submarine electric cables.** Charles Scott Snell, Culver Park, Saltash, Cornwall.

10304. **A method of generating a current of electricity during the revolution of a carriage or car wheel.** Walter Henry Pearson and Alfred Launcelot James Tait, 45, Holborn-viaduct, London.

10313. **Improvements in effecting telegraphic or telephonic communication through submerged cables, and in the construction of cables to be used for this purpose.** Willoughby Statham Smith and William Puddicombe Granville, 24, Southampton-buildings, Chancery-lane, London.

SPECIFICATIONS PUBLISHED.

1891.

17426. **Generating ozone by electricity.** Andreoli. (Second edition.)

1894.

6458. **Dynamo-electric machines.** De Ferranti.

8825. **Conducting electricity through table-cloths, etc.** Electrical Installation Company, Limited, and O'Brien.

NOTES.

Obituary.—The death, at Chester, is announced of Mr. William Clarke Deeley, chairman of the Electric Lighting Committee of the Chester Town Council.

Electric Lighting in India.—The Government of Bengal is preparing a Bill to facilitate and regulate the supply of electricity for lighting, etc., in Calcutta.

Another Alpine Railway.—Herr T. Schenkl, of Graz, has received official authority to proceed with the plans for the construction of an electric rack railway up the Grossglockner.

Recognition of Reis.—It is announced that the German Emperor has directed that an annual pension of 400 marks shall be paid to the daughter of Philip Reis, the inventor of the telephone.

Cables in the North.—H.M. telegraph steamer "Monarch" has arrived at Kirkwall. She is to be engaged in laying cables between Fair Isle and Shetland and from Rousay to the mainland.

Electric Lighting in Camp.—The 1st Monmouthshire Artillery Volunteers at Whitsuntide camped out at the old Roman encampment near Port Skewitt. The electric light was used for lighting the camp.

Projected Zinc Ring.—According to the German papers, negotiations are proceeding between Rhenish and Belgian works for the establishment of a convention to control both the production and price of zinc.

The Jeantaud Electric Stage Coach.—*Le Vélo* gives an account of the electric stage-coach service between Paris and Bordeaux which M. Jeantaud has organised. The current is obtained from Fulmen accumulators.

Electric Transmission in South Africa.—Additional power is being used in connection with the Sheba electrical transmission plant, and stone-crushers and some of the stamps have been running for experimental purposes. The full power will, it is expected, be available shortly.

New Indian Telegraph Line.—The Government of India, in the Public Works Department, have recently sanctioned the recommendation of the Director-General of Telegraphs, that an allotment of one lakh of rupees may be made for constructing the line from Mone to Kengtung.

Physical Society.—At the meeting of this society to be held on the 14th inst. papers will be read on "The Measurement of Cyclically Varying Temperatures," by Mr. H. F. Burshall; on "The Thermal Constants of the Elements," by Mr. N. F. Deerr; and on "An Electromagnetic Effect," by Mr. F. W. Bowden.

Not in a Hurry.—There has just come to hand a number of the *Bulletin de la Société Belge d'Electriciens* for the first quarter of the current year. It contains an elaborate paper by M. P. van Vloten, being a report on electric traction in Europe, read by him in August, 1894, before L'Union Internationale et Permanente des Tramways.

A Competition.—The directors of the Great Berlin Tramway Company offer six prizes of respectively 2,000, 1,000, 700, 600, 400, and 300 marks for the six most artistic designs of poles and wall rosettes for electric tramway overhead wires. Plans will be received until June 20 by Die Direktion der Grossen Berliner Pferdeeisenbahn-Aktien-Gesellschaft, Berlin, from whom further particulars may be obtained.

Engineers Wanted in Siam.—At Bangkok the machinery laid down for electric lighting was designed for 12,000 lamp power, and there are not 1,000 lamps in use, because there is no suitable agency at command for guidance and direction. Here, says *Indian Engineering*, is a chance for the competent mechanical engineer. Or he might secure profitable employment in the telegraph department, which is undermanned and vociferous for coefficients.

Telegraph Extensions.—The Postmaster-General has sent a letter to Mr. Weir, M.P., who has been pressing for telegraphic extensions on the western mainland of Rossshire and the Island of Lewis. The Postmaster-General says: "I can assure you that I am fully alive to the importance of setting to work as soon as possible on any extensions which it may be decided to carry out, and I am in expectation that the Scottish Office will soon inform me of its decision in this matter."

Electrical Trade Section.—Notice is given that a meeting of the Electrical Trade Section of the London Chamber of Commerce will be held at the offices of the Chamber on Tuesday next, the 11th inst., at 12 noon, to further consider regulations and conditions for securing the safety of the public and for ensuring a proper and sufficient supply of electrical energy made by the Board of Trade under the provisions of the Electric Lighting Acts, 1882 and 1888, together with observations made by members of the section in reference thereto.

Telephone Between Dublin and London.—The Lord Mayor of Dublin has been informed by the Postmaster-General that the Post Office Department has now completed the erection of trunk wires between London, Dublin, Belfast, Edinburgh, and Glasgow. The Lord Mayor of London has promised to be present at the London office on Wednesday, 12th inst., at one o'clock, and the Lord Mayor of Dublin has been asked to be present at the same time at the General Post Office at Dublin for the purpose of conversing with his lordship.

English Patents.—It appears from the twelfth report of the Comptroller-General of Patents, Designs, and Trade Marks that last year 25,386 patents, 21,230 single designs, and 8,013 trade marks were applied for, the number of patent applications being the largest in the group, though this was not the case with regard to the other figures. Of the 25,000 odd patent applications, 500, or 2 per cent., were made by women, about 100 being inventions connected with articles of dress. The number of readers frequenting the Patent Office library showed an advance upon the previous year, 113,374 persons having availed themselves of its use.

Electric Lighting of Railway Carriages.—We referred to this subject in our issue of 24th ult., both in our "Notes" and on p. 586, and in our last number on p. 618, and it may be interesting to add that Baurath Staberow has reported to the Railway Society in Berlin that the management of the Dortmund-Gronau-Enscheder line are satisfied, both from a technical and an economical point of view, with the electric light, which was introduced into some of their trains a year ago. Twenty-seven carriages were fitted with 85 incandescent lamps, and the total cost of the charging station, the Tudor accumulators, and necessary buildings was £1,815.

Electric Litigation on the Continent.—The ways of Continental courts of law are slow but sure. Some years ago, the firm of Ganz and Co. won an action against a Tours firm for wrongfully using their system of long-distance transmission with alternate-current transformers, which was patented by them in France. They were likewise victorious when, two years ago, the case came before the Court of Appeal at Orleans, and now this judgment has been confirmed by the Supreme Court of Cassation. An action involving the same point at issue, which Messrs. Ganz and

Digitized by Google

Co. brought against Messrs. Siemens and Halske, at Grosseto, in Italy, has also resulted in favour of the Budapest firm.

The Slavianoff Electric Welding Process.—Attention is being drawn on the Continent to the process of electrically fusing metals which M. Slavianoff has invented. It is stated to be analogous to the Benardos method, and that it can be substituted for it with advantage for metallic repairs—to fill up a crevice, restore a chipped corner, etc. The article to be treated is connected to one of the poles of a battery, the bar of metal to be used in the repairs being connected to the other pole. The two electrodes are brought together to form the voltaic arc. The bar of metal melts, and it is so fixed that the molten drops fall upon the place to be repaired. The electrodes must, of course, be made to approach each other as the bar fuses in order to obtain an uninterrupted arc.

The Brussels Exhibition of 1897.—The Commissaire-Général of the Paris Exhibition of 1900 has recently declared to an interviewer that *l'électricité sera un des éléments les plus importants de la grande exposition.* The Société Belge d'Electriciens seems to be equally anxious that at the forthcoming Brussels exhibition electricity shall play an important part. The *Bulletin* of the society thinks that the electrical section of the exposition should be classified as follows: (1) production and mechanical utilisation of electricity; (2) electro-chemistry; (3) electric lighting; (4) telegraphy and telephony; (5) various applications of electricity. It is also suggested that it would be well at the same time to celebrate the jubilee of the establishment of the first telegraph line on the Continent—that between Brussels and Antwerp.

Electricity Supply from Coalfields.—In the course of his presidential address at last week's meeting of the Federated Institution of Mining Engineers, Mr. W. N. Atkinson, Government inspector of mines for North Staffordshire, said that a subject of interest to colliery owners and mining engineers which appeared to be looming in the not very distant future was the establishment of large central installations in coalfields for the distribution of power to distant places by electricity. If this was found practicable there would be an immense saving in the cost of carriage of coal to the consumer, and a mitigation of the smoke plague afflicting so many manufacturing towns. In some cases it might even be to the advantage of colliery owners to initiate the system for the distribution of energy to groups of mines.

Electric Baths from Street Circuits.—It is stated that the employment of street-lighting circuits for electric baths has become quite customary in France. A transformer is used which lowers the potential to from 15 volts to zero. Where only a single bath is to be fitted up, as in a private residence, there is employed a combination in series of a shocking-coil and a small transformer. The whole is placed in a little marble receptacle above the bath. The secondary of the transformer moves along slides, and a rod passing to the outside enables the current to be regulated from a maximum to a minimum strength. The primary circuit is provided with an interrupter. The wires of the secondary proceed directly to the electrodes, which are simple plates of metal that can be placed anywhere in the bath by means of suspending hooks. There is also added an ampere-meter for continuous and alternating currents.

The Telephonic Sound Produced by Thermic Radiation.—M. Semmola has shown (*Comptes Rendus*) that in causing intermittent solar light to fall, by means of a lens, on the gilded metallic plate, 2mm. thick, of a Hunnings microphone, the telephone put in circuit produces a slight but very distinct sound. If the luminous ray be suppressed, the sound ceases. The intensity of the sound increases or decreases according as the intermittences of the radiation become more or less rapid. The best radiations are the thermic radiations, as the sound is louder when the metallic plate is coated with smoke-black. On the other hand, the sound is no longer heard when the luminous pencil traverses non-thermal substances before reaching the microphone. It is necessary that the tiny image of the sun which is formed in the focus of the lens, and which strikes the vibrating plate, should be fairly hot and capable of at least carbonising paper. It seems, then, that the plate suffers rapid and regular dilatations and contractions which determine the thermic vibrations.

Another "Electric Bicycle." — We hasten to chronicle particulars of the electric bicycle of M. Manger ere we are forestalled. This gentleman has taken out a patent for "the adaptation of dynamos, without accumulators, to ordinary bicycles to permit of the production at will of electricity to be used for ascending hills, and in making long cyling journeys without fatigue to the rider." His system "consists (1) of a cogwheel fixed to the pedal axle; (2) of a dynamo engaging with this cogwheel; (3) of a motor capable, if necessary, of communicating its movement by belting to the hind wheel by means of two pulleys. If the dynamo is disengaged and the belting is placed on the loose pulley of the motor, the conditions are the same as in an ordinary bicycle. If, on the contrary, the cyclist is tired or has a hill to climb, all that he has to do is to engage the dynamo with the cogwheel, and to place the belting on the fixed pulley of the motor. Current is generated by the dynamo and transmitted to the motor which connects with the hind wheel, and thus affords powerful aid to the cyclist." It is the same with all great inventions: one wonders why this simple but brilliant idea never occurred to any genius before.

Technical Instruction Conference.—The following letter has been addressed by Sir Henry Trueman Wood, secretary to the Society of Arts, to representatives of technical education committees and others interested in the subject: "It has been suggested to the council of this society that a useful purpose would be served if the society were to afford to those who are interested in technical education in different parts of the country an opportunity of meeting together and discussing the measures which the society might take with a view to enlarge the scope of its present action in this matter and thus aid local authorities in giving effect to recent legislation on the subject. There appears to be a lack of a central organisation which might deal especially with such questions as the examination and inspection of classes. In spite of the valuable work which has been done by the City and Guilds of London Institute and by other bodies, it is only in a portion of the subjects sanctioned as subjects of technical instruction that examinations are held. The wide field of agriculture and home industries is untouched, while no means are provided for anything like a general system of inspection which local authorities may call to their aid should they desire to do so. There are also other points with regard to which common action would be desirable, and the council of the society have, therefore, determined to hold a conference of representatives of the technical instruction committees of the various county councils and others with the view of eliciting their views on the subject. It is proposed to hold this conference on June 20, and to invite to it the chairmen of the technical instruction committees or other representatives who may be delegated by such committees and their directors or organising secretaries. I shall be glad if you will let me know whether you can yourself

Digitized by Google

attend the meeting and also whether your county council will depute any members of its technical instruction committee to attend."

Contact Resistance of Metals.—In *Comptes Rendus* M. Edouard Branly describes some experiments recently carried out by him in regard to the electrical resistance between two sheets of metal in close contact with each other. M. Branly employed thin sheets, 48mm. square, piled one on the top of the other and compressed together by a weight of six kilogrammes. Electric connection was made with the column by means of sheets of brass at the top and bottom of the pile of plates. When a sheet of zinc was placed between two of copper, the contact resistance was very small and remained constant; but when a sheet of aluminium was placed between two sheets of bismuth, the resistance was quite appreciable and increased with time. Thus, in one experiment, the resistance was, to start with, 0·4 ohm, and 25 minutes after the contact had been made it was 0·74 ohm, and five hours after it was over three ohms. If the experiment was varied by putting the sheets of bismuth together and separating the aluminium from the bismuth by a sheet of brass, there was no appreciable resistance. M. Branly remarks that his experiments show that for certain metals—such as copper and zinc—the surface of contact is not the seat of any appreciable resistance, but for others—such as lead aluminium, lead iron, tin aluminium, tin iron, bismuth iron, bismuth aluminium, etc.—there is an appreciable resistance. When the six-kilogramme weight was replaced by one of 26 kilogrammes, the resistances at the beginning and the resistances as measured later on were smaller, and the same was the case when the pile of sheets was compressed in a vice, but in all these cases a higher resistance was found than one would have expected according to current notions, and this resistance always increased with time. The contact resistance of two metals in air can, M. Branly states, be altered by mechanical shock or by electric spark.

Telephones and Earthquakes.—The noises which trouble long-distance telephones that use the earth to complete the circuits have been turned to account by Señor Estrada, professor of physics in the Potosi State College, as a means of foretelling earthquakes in volcanic zones. By means of the telephone and microphone, and with daily observations taken in the area including Vera Cruz, Pueblo, Mexico, and Guadalajara, Prof. Estrada believes it possible to definitely forecast earthquakes and volcanic eruptions, as the result of the great interior changes of the earth, which change the geological construction of the land. The sensitiveness of the telephone renders it admirably adapted for recording approaching seismological phenomena, and a rational study of these phenomena is proposed by the construction of various telephone lines. One line would connect the Central Government Meteorological Observatory with the base of the volcano of Popocapetl—being grounded in one of the deepest cracks or crevices, selecting among them one containing a thermal spring—connecting the other end of the line at the observatory with the metallic tube of one of the deepest artesian wells in the city. Another line, he urges, should run from Pueblo to the same mountain, and then connect Guadalajara with the volcano of Colima, and other lines to the peak of Orizaba, the Coire de Perote, and the Jorutle volcanoes. In each of these branches or sections, and with all the lines connected as often as possible without interfering with the service of the wires, Prof. Estrada proposes to place in the observatories at Mexico, Pueblo, and Guadalajara, a simple microphone composed of a pendulum suspended on a thin spiral wire, so arranged as to close an electric circuit at the slightest motion and to set an electric bell ringing, in order to record the slightest movement of the earth. By this means eruptions of any volcano and earthquake may, it is thought, be foretold many days in advance.

Electric Ploughing in Germany.—Practical experiments in electric ploughing have been made at Halle-on-the-Saale, Germany, by Messrs. F. Zimmerman and Co. Here a two-furrow tilting plough was used. The electric motor is fixed to the implement itself. The shaft of the motor, by means of a double spur-wheel gear, drives a shaft fitted with a pinion, over which a chain runs from one end of the field to the other. This chain is held taut at both ends by triple ground anchors. When the motor is put in operation it will haul the plough across the field. When the end of the field is reached the plough is tilted to the other side, and by reversing the motor the plough starts on its return journey, at the same time depositing the chain sideways for the next row of furrows. The anchors are moved by a labourer, who lifts them out of the ground with a hand lever. The current is generated by a portable dynamo and 10-h.p. steam-engine, and the current is conveyed by a cable that follows the car upon light cars, which turn readily in any direction. The power used in the heavy loamy clay at Halle-on-the-Saale was an average of eight kilowatts. The plough turned two furrows, measuring together 60cm. in width by 24cm. in depth, and, travelling at 0·9 metre per second, the actual useful effect was equal to 8 effective horse-power, which showed that there was a loss of about 4 h.p. between the portable engine and the plough. A 16-h.p. engine was used for a four-furrow plough, and the depth of the furrow was 24cm. One of the remarkable features of this system is that, guided by the tightened chain, very shallow furrows can be made with great evenness and regularity, and the balance plough can thus be used for turning over stubble land and other light work. As regards attendance, only one man is needed for the lighter plough, while for the larger one three men are required—a ploughman and a man at each end to shift the anchors. The first cost of an electric plough is said to be much below that of a steam cultivating plant. A steam-plough, with two portable engines, will cost from 40,000 to 60,000 marks, but Messrs. Zimmerman and Co. can supply a four-furrow balance plough, with electric motor and reversing gear, as well as 250 metres of chain, two anchors, 600 metres of insulated cable, and six cable cars for £500, while the entire outfit for a three-furrow plough costs £400, and for a two-furrow plough £300. In addition to this, the dynamos will cost about £220, £200, and £100 respectively. According to the figures published as to the results of the trial, the working expenses of an electric plough are about half that of steam ploughing, and if these results are borne out in practice upon an extensive scale, there seems to be no question of the future of the electric plough.

Magnetic Strains. — Prof. C. G. Knott, D.Sc., F.R.S.E., and Mr. A. Shand have presented before the Royal Society of Edinburgh a further note on the volume changes which accompany magnetisation in iron and nickel tubes. In their previous communication in July last they gave the broad results for three nickel tubes of various bores. In these experiments the screw stopper through which the capillary glass tube passed was made of brass. This brass stopper was used because of the comparative difficulty of working nickel. The authors were led in the course of some tentative experiments to use this brass stopper with one of the steel tubes. In the earlier experiments with the iron and steel tubes they had used an iron stopper. They were hardly prepared, however, to find that the mere substitution of a brass for an iron stopper should

Digitized by Google

produce such a marked effect, not only on the amount of change of volume in given magnetic fields, but also on the manner in which the volume change varied as the field increased or decreased steadily. This result at once proved that it was absolutely necessary to furnish the nickel tubes with a nickel stopper, and in the present note the authors give a comparison of the volume changes in steel tube V with (1) an iron stopper; (2) a brass stopper, and of the volume changes in nickel tube, I with (1) a nickel stopper; (2) a brass stopper. The numbers in the first column give the magnetic fields, the others represent dilatations or changes per unit volume, the unit being 10^{-7} cubic centimetre.

Field.	Steel tube, V.		Nickel tube, I.	
	Iron cap.	Brass cap.	Nickel cap.	Brass cap.
560	−58·7	− 0·6	−110	−107
500	−42	− 9·6	−109	−106
400	−30	−18	−107	− 98
300	−18	−12	− 96	− 89
200	0	− 7·2	− 72	− 67
100	+ 7·2	− 2·4	− 29	− 23
50	+ 3·0	− 1·2	− 4·5	− 4·5

In the case of the nickel tube the difference in the two columns is not of any great moment. With the nickel cap or stopper the changes of volume are slightly greater. This is very much what one would expect to find; for the nickel stopper has the effect of lengthening by an inch or so the magnetisable bar, and the tube portion of the bar so lengthened will be more effectively magnetised than when the stopper is of a non-magnetic metal. But it will be noticed that the behaviour of the steel tube is greatly altered when the brass cap is substituted for the iron cap. Thus there is no change of sign in field 200 when the brass cap is used, and there is no maximum negative dilatation in field 400 when the iron cap is used. In short, the character of the stopper has a marked effect upon the whole character of the strain. It is easy to see that the iron stopper will tend to increase the induction into the tube, but except in the way of diminishing the induction, and so altering the accompanying change of length, the authors cannot credit the brass stopper with any effect upon the longitudinal strain. It is as a disturbing factor in the transverse strain that it has to be considered. It does seem extraordinary, however, that a stopper whose hampering action is confined to one end of a fairly long tube should, by its inability to yield to the magnetising forces acting on it, produce such a marked effect upon the volume changes taking place in the tube as a whole. A closer investigation of the phenomenon may throw some light on the character of the strains accompanying magnetisation.

Electric Lighting of the North Sea-Baltic Canal.—The electric lighting arrangements in connection with the North Sea-Baltic Canal have been carried out by the Helios Company, of Cologne, who have for the past 10 years exploited in Germany the alternating-current transformer system. The following principles were laid down for the scheme, which comprised not only the lighting of the canal but of the locks, harbours, buildings, and harbour lighthouses: (1) two central stations were to be established, one at Holtenau and one at Brunsbüttel; (2) the stations were to be supplied with the safest and economical machinery and apparatus, with an ample reserve; (3) the tension of the current in both stations was to be kept constant whatever the change in the load might be; (4) each lamp was to be independent from the others, so that in the event of a large number of lamps being extinguished there should be no effect on those which remained lighted. At both ends of the canal, central machinery-houses have been established for the hydraulic plant operating the locks, and also for the electric lighting plant. Each installation has two low-speed steam dynamos of 200 h.p., running at 85 revolutions per minute. The engines are horizontal tandem engines with governors, by the Augsburg Machinery Works. An alternating-current dynamo is coupled direct to each engine, the magnetic field being combined with the flywheel. With their normal load, the output of the steam dynamos is 100 kilowatts. At Brunsbüttel there is a small additional steam dynamo of 12 h.p. for lighting the lock chambers during the daytime. For the lighting of the boiler and machinery houses, the buildings, the locks, and the harbour lights, the high-tension current of 2,000 volts is transformed to the required pressure by Helios transformers. There is a large number of arc and incandescent lamps both at Holtenau and Brunsbüttel. The standards at the locks have each four lamps of 25 c.p. The conductors are mainly carried underground, and consist of concentric armoured cables. For lighting the canal, which is 98 kilometres, or, say, 60 miles, in length, there are four divisions, one for half the length on either side. Each division has 250 incandescent lamps of 25 c.p., so that the distance between each lamp averages between 600ft. and 700ft. There are lakes, however, on the course of the canal, and these being lighted by gas buoys, and not electrically, the electric lamps are really closer than shown by the average calculation, the distance between them varying from 260ft. to 800ft. Overhead copper 4mm. conductors are used for the lighting of the canal. The installation has proved to be very efficient, and to fulfil the conditions laid down. We shall give further particulars, with illustrations, of this undertaking at an early date.

Technical Education in London.—The annual report of the Technical Education Board of the London County Council records the progress made in "co-ordinating and supplementing the provision for all the varied branches of technical education in London" during the past year. In the intermediate or secondary schools, in the evening classes, in every branch of science and technology, in all the departments of art training, and in the various subjects included under the head of domestic economy a great deal of work has been done. The main object has been to afford additional inducements and facilities for the poorest parents to keep their children at some secondary or continuation school after leaving the elementary school. The award of the intermediate and of the senior county scholarships establishes the link between the public elementary school and the university or technical college of university rank, while the scholarships and exhibitions in domestic economy, in art, in science, and in technology, the report states, are giving additional stimulus to the study of these subjects, and offering facilities to many who are engaged in trades or handicrafts to pursue special studies that will help them in their callings. The junior county scholarships which are open to boys and girls under 13 years of age offer free education for two years, together with money payments amounting to £20 in the two years, and have been eagerly sought after. In November, 1893, there were under a thousand competitors; at the examinations held last month the entries numbered 2,084. The success which has attended these scholarships has induced the Board to award 600 instead of 500 as originally proposed. The intermediate scholarships give education up to the age of 19, together with money payments rising from £20 to £35 a year. At the first examination, held last year, 348 candidates presented themselves, 148 being girls; and the competition proved so good that the Board decided to award 50 scholarships instead of 30, as originally proposed. Of these, 35 were

Digitized by Google

awarded to boys and 15 to girls. Very favourable reports have been received of the progress of the intermediate scholars; two have passed the London matriculation in the first division, and several others have distinguished themselves in public examinations. Next come the senior county scholarships, which are intended to afford to the most promising and deserving students an opportunity of receiving that advanced instruction at universities, or institutions of university rank, which they would otherwise be unable to obtain, and they give free education together with a money payment of £60 a year. There are now over 600 county of London scholars attending intermediate or secondary schools. A sum of nearly £15,000 has been devoted during the year towards aiding these schools, and a grant of £1,000 has been made to University College and £500 to Bedford College. Turning to polytechnic and evening instruction, the Board expresses satisfaction at the high standard of quality and thoroughness to which the instruction given in these institutions has been raised. The total annual expenditure of the eight institutions open last year amounted to £90,000, their total number of students to 27,000, and their aggregate number of separate classes or courses of lectures to over 1,250. The aid given to the polytechnics takes the form of grants made on conditions calculated to promote efficiency. The Board's financial position is as follows: The appropriated balance on April 1, 1894, was, in round numbers, £31,000. The County Council made a further grant for 1894-95 of £57,000. During the year there was appropriated £64,000, leaving a balance unallotted of about £24,000, which is carried forward to next year.

Electricity in Medicine.—We have received from Dr. William James Morton, professor of electro-therapeutics at the New York Post-Graduates' Medical School and Hospital, a pamphlet on "Electricity in Medicine: from a Modern Standpoint," being a contribution to a discussion before the Medical Society of the State of New York. He says that there are times in the history of the world—in the history of medicine—when certain subjects are rife. Such a period is now with us as regards electricity, and physicians cannot, even if they strive to do so, keep out its influence. Electricity has revolutionised chemistry long since—the fundamental laws of chemistry and electricity are but two aspects of one and the same thing; it has revolutionised physics, for light, or the science of optics, and the science of electricity are now regarded as one and the same science; it is now revolutionisng the industries and the habits of mankind. Electricity will not revolutionise medicine, and not even the therapeutics of medicine; for medicine is a complex science, built upon many foundations where electricity is not directly involved, and therapeutics seeks aid from every quarter, and electricity is but one of these aids. But in this, the electric age, the physician alone of educated men cannot remain isolated from the general advance, cannot lag behind in this great branch of scientific thought and practice; for it is he who, in the race for the good and the happiness of the human kind, has ever kept in the vanguard of information in the physical sciences even at great sacrifices to his personal comfort and without remuneration. Electro-therapeutics must partly be narrowed down to specialists. Its advanced and best work must certainly be in such hands, but there still remain a large number of specific procedures of great importance in medicine and surgery which may be perfectly grasped and aptly applied by the general practitioner. And the number of such procedures will more and more increase as the medical schools of the land adopt or perfect teaching of elementary electro-physics in their curriculum, and as the newly-trained men spread outward to their work. If the physician does not take up this question he will be hopelessly behindhand in a branch of science which now closely interests the entire civilised world, and there can be no doubt that in not taking it up he may be charged with neglecting the interests of his patients. Furthermore, he cannot decide upon the merits of the uses of electricity in medicine if he is in entire ignorance of the subject. The true position to-day is that of conservatism—a conservatism based upon knowledge of the subject, and not that pseudo-conservatism based upon scepticism; for a blind and unreasoning scepticism has no place in science any more than an equally blind faith. There can be no doubt that in selected cases, and with skilled use, electricity can render to medical practice important aid, now unavailable by reason of the inadequate attention paid to the subject. And after dealing with electro-physiology and electro-therapeutics Dr. Morton comes to the following conclusions: (1) that a definition of electro-therapeutics in a biological sense is that it is the transformation (by the law of conservation of energies) of electric energy into the energy peculiar to vital cells; (2) electricity in medicine must be regarded not as an entity, like a drug, but as having a variety of "properties," such as electrolysis, cataphoresis, contraction of protoplasm, etc., each of which properties may be employed singly or combined to combat given morbid conditions or diseases; (3) of the galvanic current it may be concluded: (*a*) that strong currents depress nutrition of tissues, and produce structural changes leading to physiological atrophy (twenty to a hundred milliamperes); (*b*) that mild currents stimulate nutrition and produce physiological hypertrophy (one to eight milliamperes); (*c*) that mild galvanic currents, pulsating or alternating, produce similar effects to mild continuous currents; (*d*) that the negative pole is specifically indicated in that large class of cases termed chronic inflammation where newly-formed fibrous tissue or exudate occurs; (*e*) that upon the writer's theory—already accepted by several prominent physiologists—and observations, that catabolic or destructive events in tissue uniformly present the sign of negativity—that is to say, are at their origin electro-positive (resembling the zinc of a voltaic cell), the negative pole is indicated to arrest the catabolism, the positive to augment it; (*f*) that the positive pole is rarely indicated, and, if so at all, upon the basis of an electro-tonic effect to produce sedation of neuralgic pain in superficial nerves. (4) Of the Faradaic current it may be concluded—(*a*) that its main uses are to tetanise muscle and to cause sedation of pain; (*b*) that the tetanising current as now employed to treat paralysed muscles is injurious, since it enfeebles the muscle and causes atrophic structural changes; (*c*) that to strengthen or properly exercise a paralysed muscle, a slow rhythm of the Faradaic current—about 30 waves to the second—should be adopted; (*d*) that in some spastic conditions of muscles—due to paralysis of an opposing group—the strong tetanising current may be used to advantage to overstimulate and thus to fatigue the muscle; (5) of the Franklinic current, or statical electricity, it may be concluded that it is an adjunct of great efficiency in practice, since (*a*) it evokes the usual nerve and muscle reactions; (*b*) it affords a most convenient means of stimulating the peripheral distribution of the nerves in the skin, producing counter irritating, reflex, and other afferent impression effects; (*c*) it has a local perturbatory action (spark); (*d*) it produces profound alterations in the metabolism of the individual, increasing the natural waste products, and diminishing the toxic or by-products. For this reason, it is specifically indicated in cases of malnutrition, whether local or general.

ELECTRIC LIGHTING OF TRAINS.—IV.

BY R. W. WEEKES, WHIT.SCH., A.M.I.C.E.

(Continued from page 622.)

GREAT NORTHERN RAILWAY COMPANY.

In July, 1886, the Great Northern Railway Company applied the electric light to one of their metropolitan trains, and subsequently to other uncoupled trains. A dynamo, together with certain accumulator cells, was placed in the guard's van, and driven by belting, or more direct means, from the axle of the vehicle. Automatic apparatus was provided, by which the direction of the current in relation to the accumulators was controlled, and the dynamo connected to the batteries when it had attained the necessary speed, and had consequently the requisite E.M.F. The dynamo, the cells, and the lamps were all arranged in parallel circuit—two main cables being led from the cells throughout the train. The system of lighting was practically that usually adopted in stationary or domestic installations, with the addition of the necessary automatic apparatus for controlling the current evolved by the dynamo under the varying speed and direction of the train.

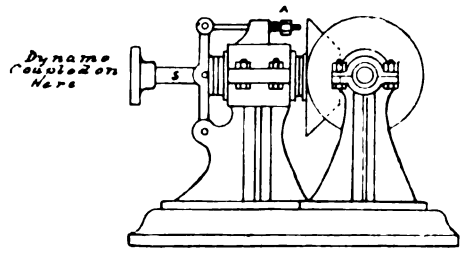

FIG 20

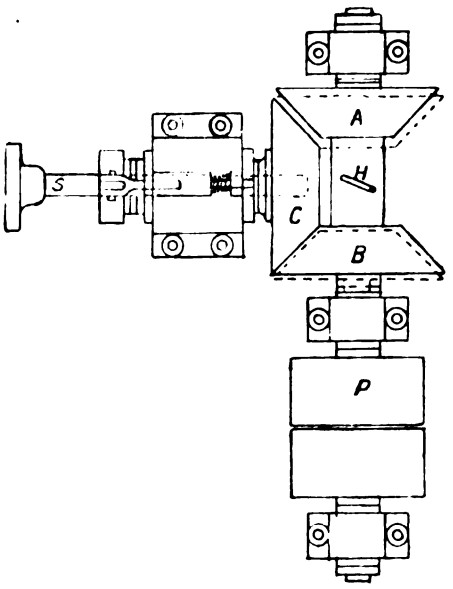

FIG. 21.—Friction Cone Gear for Automatically giving Uniform Direction of Rotation to the Armature.

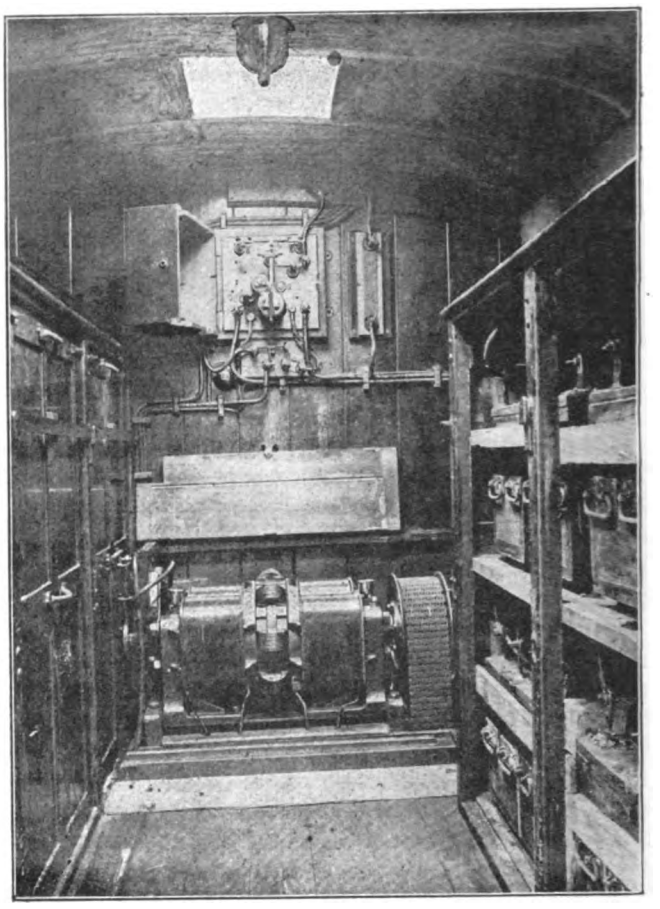

FIG. 22.—Train-Lighting Compartment on the Great Northern Railway.

Commencing to light the trains electrically at this early date, the company had to depend on the inventive genius of its own officials to a very large extent. Mr. T. Ireland and Mr. F. W. Cook took the matter up vigorously, and have made several successful departures from recognised practice. As in almost all engineering work, the success of the lighting gears is ruled by the details of construction, and it is to details that so much attention has been given by the officials of the Great Northern Railway Company. At first, an attempt was made to ensure uniform direction of rotation of the armature independent of the direction in which the train was travelling.

The construction of the mechanical gear by which this result was obtained, and which was used for several years, is shown in Figs. 20 and 21. The belt from the axles of the guard's van drove the pulley, P, the direction of rotation varying with the direction in which the train was travelling. This pulley was keyed on to the shaft running through the sleeve, on which were keyed two friction cones, A and B. This sleeve was free to move through a small arc, while the pin, H, traversed the spiral slot, H. The dynamo shaft was coupled rigidly to the shaft, S. The friction cone C was free to slide to and fro on this shaft, but was prevented from turning by means of a sunk key. The method of working was as follows: If the belt on the top of the pulley, P, is moving from left to right, the pin will move with the position shown in Fig. 20. The spirality of the groove, H, will bring the friction cone B into gear with C. This cone C was held up to its work by a spiral spring, X (Fig. 21). Now, if the train stopped, and began to travel in the opposite direction, the pin moving back through slot H will bring the cone A into gear with C. This will counteract the different sense of rotation of the shaft driven by the pulley, P, and keep the direction of rotation of the dynamo constantly the same. Mr. Cook assures me that this apparatus was fairly successful, but it was naturally found that it was easier to reverse the electrical connections and to alter the lead of the brushes than to mechanically reverse the direction of motion. The dynamos used in these first trains were of the Brush open-coil type, as described in a previous article.

The present arrangement of machinery for electrically lighting the trains of the Great Northern system is shown in Fig. 22, and again in elevation in Fig. 23. All the machinery is placed in a small compartment adjoining the guard's van. The dynamo is at the further end, as shown, the brush rocking gear being behind the set of accumulators on the right. On the left-hand side, the accumulators run the full length of the compartment. As will be seen from Fig. 23, there is a countershaft directly under the dynamo, and the belt-tightening gear is so arranged that one movement tightens both belts simultaneously. In this case, one belt only is used both from the countershaft to the dynamo and from the axle to the countershaft. The rest of the apparatus is shown either diagrammatically in Fig. 23, or in perspective in Fig. 22. The use of the various parts can best be seen by the diagram of connection, Fig. 24. The current from the brushes goes to the pole reverser, P, which is placed at the left-hand side of

Digitized by Google

the dynamo. This reversing switch is worked by two friction surfaces working against a plate on the shaft, which can be seen in Fig. 22.

The details of the switch showing the trailing friction surfaces and the brush connections are shown in Fig. 28.

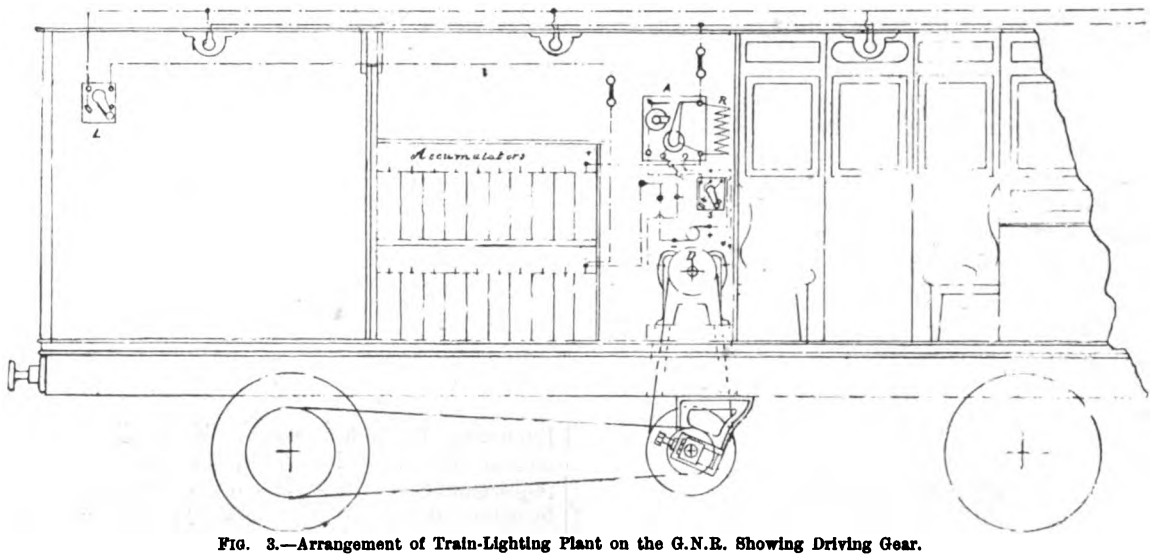

FIG. 3.—Arrangement of Train-Lighting Plant on the G.N.R. Showing Driving Gear.

From this reversing switch the current passes to a hand switch, G S, which cuts off the dynamo in case of emergency. From this it goes to the automatic switch, which is placed above the dynamo. The connections of this switch are shown in Fig. 25. The shunt coil in this apparatus connects the dynamo to the battery when the voltage rises to that required to charge the accumulators.

The automatic variation of the lead is effected by an exceedingly neat combination of governor balls and drag links. The method is shown in Fig. 27. In the driving pulley there are two weights working on guides. Springs hold these down in the position shown when the machine is at rest, but on the speed rising they fly out and actuate the levers, G G. From the other ends of these levers two drag links

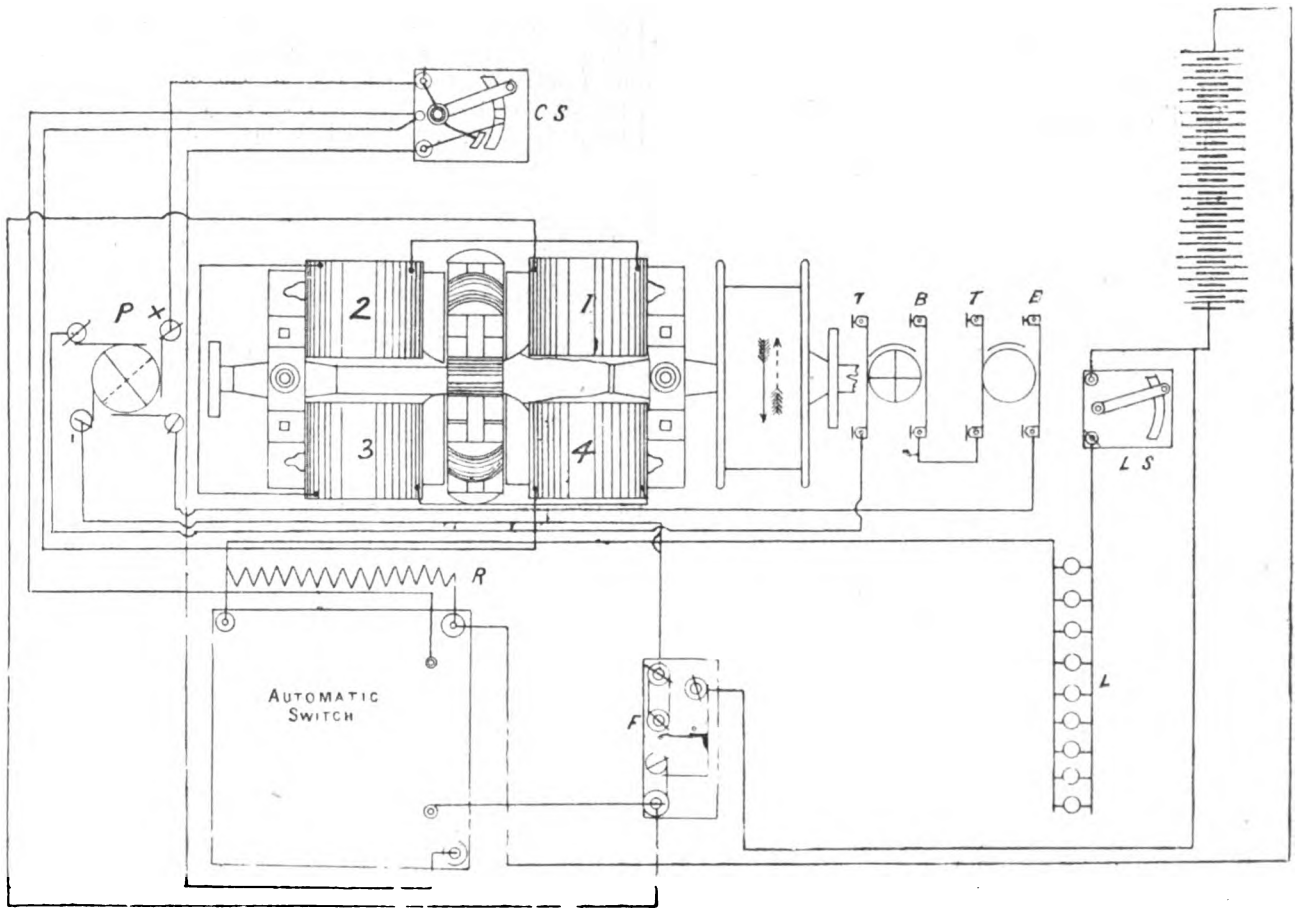

FIG. 24.—Diagram of Connections.

At the same time, resistance is automatically put into the lamp circuit to prevent the lamp being over-run due to the charging pressure being above that of the discharge.

A fuse board, F, and a lighting switch, L S, are also provided. The brushes and brush gear form one of the essential features of this system. The brushes consist of thin sheet-copper springs, Fig. 26, placed end on on the commutator. Some four or five of these springs are placed side by side, so that on the average at least four are making good contact with the commutator segments. One steel spring forces these copper springs down as they wear away, and the holders, of which there are two to each commutator, are also supported by steel springs.

connect on to the commutator bush, and move it round the shaft to a position varying with the speed. The direction in which the motion takes place is determined by the direction of rotation, as the force required to drive the commutator, which is otherwise loose on the shaft, is sufficient to give the just slight obliquity in one direction or the other.

The commutators, brushes, and all the small parts

Digitized by Google

connected with this gear are made at the company's own workshops, at Finsbury Park, under the superintendence

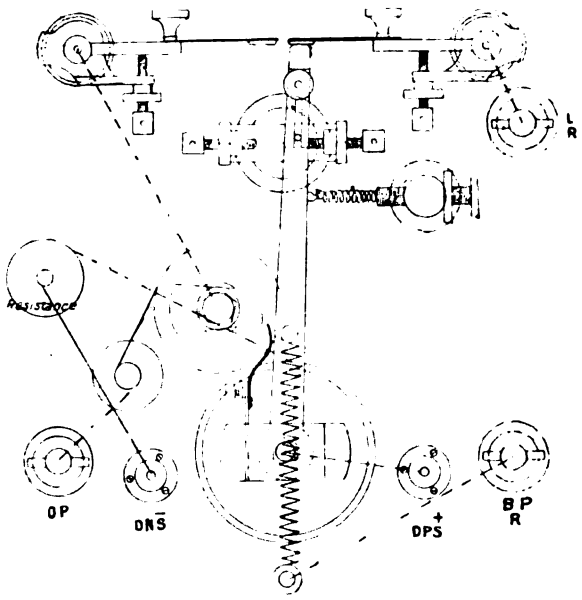

FIG. 25.—Connections of Switch for putting the Dynamo into Circuit, etc.

of Mr. C. J. Cooke, who has charge of the whole of the electric lighting on the trains.

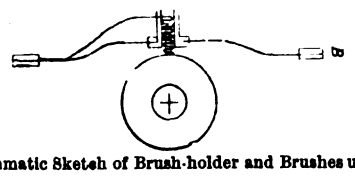

FIG. 26.—Diagrammatic Sketch of Brush-holder and Brushes used on the G.N.R.

The accumulators, of which there are 22 in each coach, are of the E.P.S. manufacture, and are placed in stands at either side of the compartment, as shown in Fig. 22.

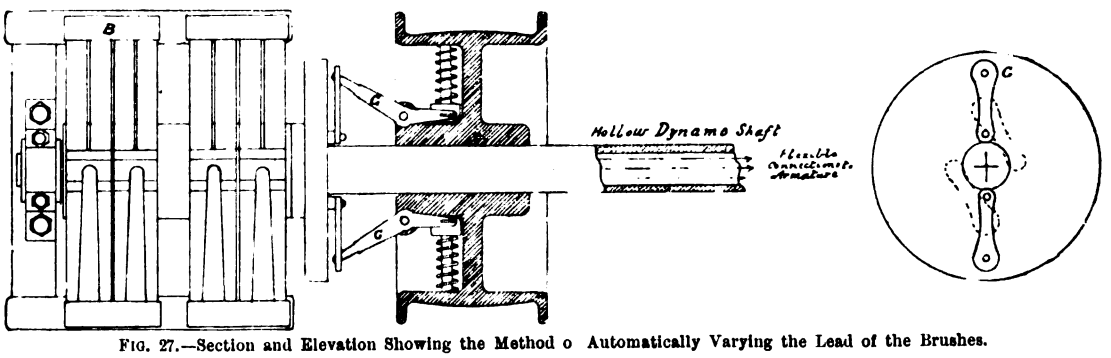

FIG. 27.—Section and Elevation Showing the Method o Automatically Varying the Lead of the Brushes.

Strong wood panelling prevents accidental damage being done to them by the attendant while seeing to the dynamo, and they are carefully wedged in their places.

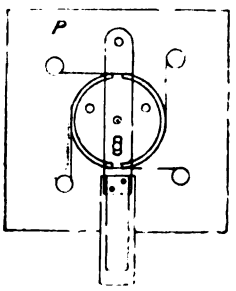

FIG. 28.—Reversing Switch and Gear.

The train consists of 11 coaches, and the candle-power provided is as follows:

8 first-class compartments with one	16-c.p.	lamp	in	each	= 128 c.p.
20 second-class ,, ,, ,,	12	,,	,,		= 240 ,,
20 third-class ,, ,, ,,	8	,,	,,		= 160 ,,
3 brake-van and dynamo ,, ,,	8	,,	,,		= 24 ,,
					552 ,,

Eight trains are now fitted and in regular work, and the cost per train per annum for upkeep is about £150. The rest of the figures for cost, etc., kindly furnished by the engineers of the company, are as follows: initial cost of outfit, £36. 7s. 2d. per carriage; average candle-power per carriage, 50; cost of supplying the light per candle-power hour, ·0258d. The regulation of the E.M.F. will naturally have the same faults as were described on the Brighton system, as the same type of dynamo is used. Still, although with wide ranges of speed the variation of voltage exceeds somewhat the Board of Trade standard, the light is practically successful, and on ordinary trains is really first-class.

THE ELECTRICAL LABORATORY OF THE CITY OF LONDON COMMISSION OF SEWERS.

In order to be able to commence work at once, Mr. A. A. Voysey, the electrical inspector of the above Commission, has fitted up a temporary laboratory in the Wool Exchange, Basinghall-street. New offices and extensive laboratories are being built, but in the meantime the requirements of the public using the electric supply can be attended to from the laboratory, which we inspected last week.

A well-lighted room, 29ft. by 23ft., has been rented for the purpose, and Mr. Voysey has been busily employed in designing and arranging the present testing appliances. There is no doubt that the experience gained with these temporary arrangements will serve as an excellent guide when the new premises are ready to be equipped.

The testing of electricity meters is expected to be the most extensive work of the laboratory, and the following arrangements have been made for this purpose. Alternating current at 100 periods is supplied at 200 volts from the two outside wires of the City of London Electric Lighting Company's three-wire system. The primary of a special 10-unit transformer, manufactured by Messrs. Ferranti, Limited, is connected to these mains. There are three secondary windings on it—one wound to give 100 volts and two amperes, another to give from 90 to 110 volts, varying by two-volt steps, and two amperes; the third winding will give any voltage from 2 to 20 volts, varying by two-volt steps, and 500 amperes. The 100 and 110 volt coils are intended to supply the shunt coils of meters, and are joined in series. A 13-way commutator is provided by which the pressure of the supply to what we may call the shunt circuits of the meters can be varied from 90 volts to 110 volts, by steps of two volts, or from 190 volts to 210 volts by similar steps. The third secondary supplies current at low pressure to a separate circuit to which are connected the electrical quantity meters or the series coils of electrical energy meters. A commutator which will carry the full current of 500 amperes, and by which the pressure may be varied as required from 2 to 20 volts, is connected up to the thick-wire coils of the transformer. The current passes from the commutator through fuses and a double-pole switch to a copper strip extending round two sides of the room (Fig. 1). A polished teak board, 4½in. by 1½in., supported by iron bolts fixed in the wall, carries the 1½in. by ⅛in. copper strip, the lead being screwed on the back of the teak and the return bar on the front. The copper strip is enamelled bright blue and shows up well on the polished

Digitized by Google

teak. Slate shelves on solid wood corbels are arranged on one side of the room, 2ft. 6in. below the copper strip and 3ft. from the floor. These carry the standard measuring instruments, which consist of four Kelvin instruments—*i.e.*, deci, deka, and hekto ampere balances, and a watt balance reading up to 20 kilowatts. Two Kelvin multicellular electrostatic voltmeters are placed on the buttress, as shown in Fig. 1, for the purpose of measuring pressure. Above each balance the copper strip is cut and the instrument connected across the break, those not in use being short-circuited by means of a copper bar with winged nut terminals. Similar breaks are provided for the insertion in the circuit of meters and a non-inductive resistance for regulating the current. The pressure leads are placed on the top of the teak board, and are accessible at any part.

The non-inductive resistance for regulating the current in the series coil is arranged on an ingenious system by Messrs. Ferranti and Co., Limited. It is a particularly neat and compact apparatus, similar in principle to that made by the same firm for the purpose of meter testing at Portsmouth. Five vertical copper rods connected together at the top by a copper bar are surrounded concentrically by German-silver wires of slightly different lengths, which are also connected together at the top, but insulated from the copper bars. Below each set of wires is a mercury-cup, which can be raised or lowered by a hand-wheel actuating a screw. As the cup is screwed up, the ends of the different German-silver wires dip successively into the mercury. In this way they are put in parallel and connected in series with the copper bar which carries the current down into the mercury-cup. The first set of resistances consists of 10 wires, each carrying one-tenth of an ampere, or a total of one ampere when all are in circuit; the second consists of nine wires, each carrying one ampere, or a total of nine amperes; the third of seven wires, each carrying 10 amperes, or a total of 70 amperes; the fourth of seven wires, each carrying 20 amperes, or a total of 140 amperes; and the fifth of seven wires, each carrying 50 amperes, or a total of 350 amperes. Therefore, when the five cups are all in their highest position, the resistance will carry 500 amperes. It would be quite easy, if required, to provide the observer at any of the balances with a means of regulating the resistance, by cords passing from the hand-wheels on the mercury-cups round the room. The great advantage, besides the cost of adjustment, is that the wires being straight, and everywhere exposed, the final temperature is reached very quickly. For the purposes of measuring conductor and insulation resistances, comparing capacities and potential differences, a Kelvin reflecting galvanometer and testing table is provided. The galvanometer has separate high and low resistance coils, and is placed with a Jacob transparent scale on brackets let into a solid-brick pillar. Opposite it is the testing table, with a sloping top of polished teak, on which are fixed a four-dial Wheatstone bridge, a standard $\frac{1}{4}$ meghom, a ·3 microfarad standard condenser, and two Carhart-Clark standard cells, with galvanometer shunts, short-circuits, battery commutator and reversing key, and circuit commutators. The connections are so arranged that the alteration in the position of two plugs effects the change from the Wheatstone bridge connections to the connections for the direct deflection test for insulation or capacity. On a shelf below are two trays containing 100 dry cells and four Leclanché cells. The table and instruments have been supplied by Messrs. Nalder Bros. A standard barometer and thermometer are also provided.

The general view of the laboratory is shown in Fig. 1, and from it the arrangement of the various apparatus can be understood. The only point on which we do not agree with Mr. Voysey is in the arrangement of his current circuits. The low-voltage method is excellent, but the main copper bar and resistance adjustments do not readily admit of more than one class of instrument being tried at one time. In the same way, all the three Kelvin balances are in series on the strip, and cannot conveniently be used for different currents at the same time. We understand that Mr. Voysey means to use commercial ammeters in parallel circuits, and to regularly calibrate these instruments against the Kelvin balance.

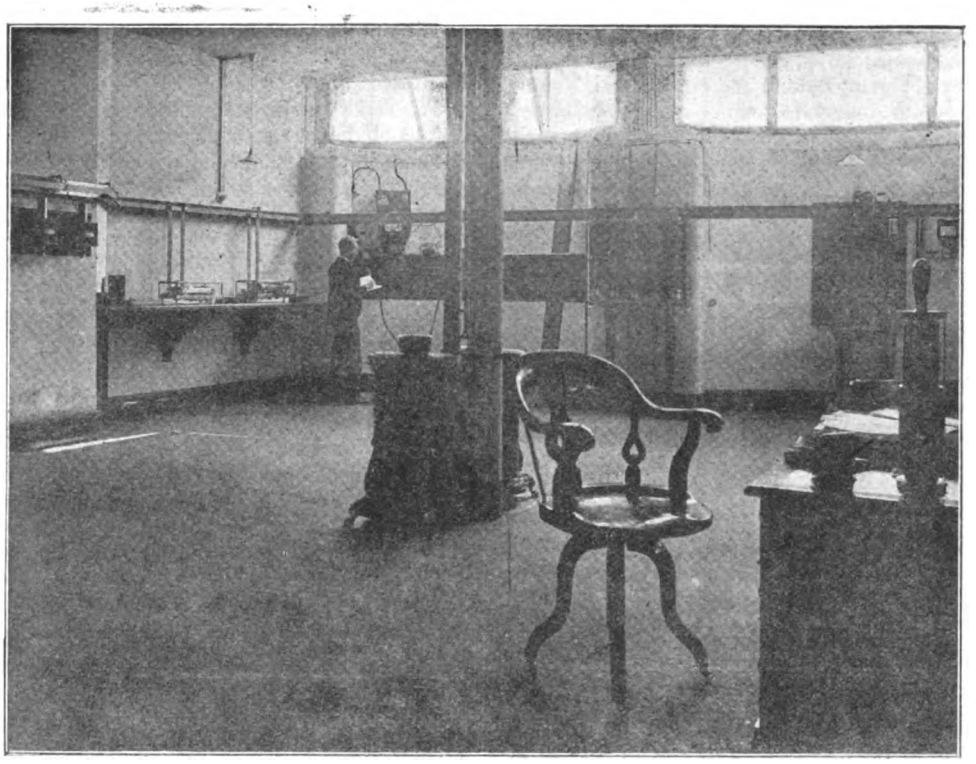

FIG. 1.—Electrical Laboratory of the Inspector for the Commission of Sewers

As the duties of the electrical inspector of the Commission of Sewers are not generally known in full, we give herewith the details of his duties as approved by the Commission recently. We were allowed by Mr. Voysey to see the record book of the faults in the City arc lighting. As is well known, the police report regularly all such faults they observe, and the City of London Electric Lighting Company's officials have to report on the cause of the failures observed. Since October last, on a large number of circuits, the faults in arc lamps reported range from four to seven, a fact which redounds to the credit of the lamp trimmers and all connected with the public lighting of the City of London. We wish Mr. Voysey every success in his new laboratory, and congratulate him on the outfit of it.

Duties of Electrical Inspector and Scale of Fees under the Electric Lighting Provisional Orders, approved by the Commissioners of Sewers, March 5, 1895.

Meters.—He shall test meters when required to do so by the undertakers, or any consumer, on the payment of the proper fee, and shall certify meters in accordance with the conditions of the provisional orders.

Undertakers' Lines and Works.—He shall follow and check, as far as possible, the testing done by the undertakers, and shall make additional tests whenever such appear to be necessary. The tests shall be made in accordance with the conditions of the provisional orders.

Undertakers' Instruments.—He shall report from time to time as to the necessity of testing and taking readings of the undertakers' instruments, and shall take such readings or tests when required to do so.

Testing on Consumers' Premises.—He shall test the electric pressure at consumers' terminals, and the undertakers' lines or works on the consumers' premises, if required by a consumer. He shall also, on any consumer's order, test his wires and fittings, where dispute has arisen between undertakers and consumer as to the condition of such wires and fittings.

Report of Testing.—If any test is made on the requisition of a consumer, the undertakers, or the Commission, a report of the result shall be made to him or them, as the case may be, on the following day. All tests shall be recorded and reported to the Commission.

Electrical Inspector's Duties Relating to Public Lighting.

Lamp Failures.—He shall supplement the work of the police, as far as possible, by reporting defects and failures in the public electric lighting.

Energy Supplied to Lamps.—He shall test the energy supplied to the public electric lamps from time to time, to see if it is up o contract value.

Lighting Failures.—He shall investigate and report on failures in the public electric lighting when they occur.

Cost of Altering Lamps.—He shall watch alterations to existing public electric lamps, and check and certify the accounts for such works.

Electrical Inspector's Duties Relating to Public Safety.

Board of Trade Regulations for Safety.—He shall ascertain, as far as he can, whether the Board of Trade regulations concerning public safety are adhered to by the undertakers, and shall report any cases in which he may find that they are not. He shall also report anything in the operations or system of the undertakers which he may consider a possible source of danger.

Electrical Inspector's Duties.—Sundry.

Progress Reports.—He shall make weekly reports of the street works executed by the undertakers, and shall inspect such works in progress as often as possible.

Public Convenience During Street Works.—With a view to the electrical engineering necessities of the street works, he shall consider the possibility of reducing public inconvenience caused by the works, and make what suggestions he can.

Board of Trade Regulations as to Supply.—He shall ascertain, as far as he can, whether the Board of Trade regulations as to supply are adhered to by the undertakers, and shall report any cases in which he may find that they are not.

Failures in the Private Supply.—He shall investigate and report on failures in the private supply.

General.—He shall perform such other duties as may appear to obviously belong to the work of an electrical inspector; and, as experience directs, may report from time to time on the necessity for adding to or modifying the above list of duties.

SCALE OF FEES FOR TESTING.

Examining Meters for Certification.	£	s.	d.
Single meters, any type, up to six kilowatts	0	10	0
Above six kilowatts, but not over 12 kilowatts	0	15	0
Above 12 kilowatts, but not over 30 kilowatts	1	0	0
Above 30 kilowatts	1	10	0
For batches of not less than six meters of the same capacity and type, up to six kilowatts, per meter	0	5	0
Above six kilowatts, but not over 12 kilowatts, per meter	0	7	6
Above 12 kilowatts, but not over 30 kilowatts, per meter	0	10	0
Above 30 kilowatts, per meter	0	15	0
Tests of Undertakers' Instruments.			
Voltmeters.			
Single, any type, reading up to 300 volts	0	5	0
In batches of not less than six, any type, per instrument	0	2	6
High-pressure voltmeters, each	0	10	0
High-pressure voltmeters, in batches of not less than six, per instrument	0	5	0
Ammeters.			
Single, any type, up to 50 amperes	0	5	0
Above 50, but under 100 amperes	0	7	6
Above 100, but under 250 amperes	0	10	6
Above 250, but under 500 amperes	0	15	0
Above 500	1	0	0

In batches of not less than six of same capacity, for each instrument one-half of the fee fixed for a single instrument of the same capacity.

Mains.			
Insulation, each test	0	10	0
Conductivity, each test	0	10	0
Service lines.

INSTITUTION OF CIVIL ENGINEERS.

The annual general meeting was held in the hall of the Royal United Service Institution on Tuesday, the 28th ult., Sir Robert Rawlinson, K.C.B., president, in the chair.

The report of the council commenced by referring to the change that had taken place in the roll of the society during the past 12 months, during which 29 members, 286 associate members, and five associates had been elected, and two members and three associate members were restored to the roll; while the deaths, resignations, and erasures amounted to 170. The net increase was therefore 155, or at the rate of nearly 3 per cent. per annum. The numbers of all classes on the books at the end of the institution year were: honorary members, 17; members, 1,862; associate members, 3,687; associates, 355—making a total of 5,921. Attached to the institution, though not forming part of it, was the student class, the conditions of admission to which had continued to exercise the earnest attention of the council. For the first time since the introduction of the higher qualifications of candidates for admission as students, the council was able to report an effective increase in the roll, the number on March 31, 1895, being 816, or 25 more than at the same date last year.

The statement of accounts, as vouched for by the auditors, showed that the receipts of the year had been—on income account £20,970. 3s. 10d., on capital account £8,933. 1s. 2d., and on trust funds account £445. 13s. 2d.—together £30,348. 18s. 2d. The general expenditure amounted to £18,385. 10s. 11d., which included the cost of four volumes of *Minutes of Proceedings*, part payment for the subject index to vols. lxix.-cxviii., the revision and printing of the new library catalogue, and the succession duty on the Palmer bequest. Capital expenditure had absorbed £7,130. 8s. 11d., mainly on account of the new building, and trust funds expenditure £492. 9s. 6d.—together £26,008. 9s. 4d. The Palmer scholarship previously mentioned represented a bequest of £1,500 (less legacy duty and subject to a life interest) from the widow of a former vice-president of the institution, to be devoted to the foundation of a scholarship at Cambridge University, tenable by the son of a civil engineer in need of such assistance. This bequest, reverting to the institution by the death of the holder of the life interest, had been diminished by the legacy duty on the first succession to £1,381. 1s. 6d., which sum was invested in the Metropolitan Board of Works 3 per cent. stock. Under the new estates duty this sum became further liable to a charge of £173. 2s. 3d. In order, therefore, that the fund might not be depreciated to an extent incompatible with giving proper effect to the generous founder's object, the council decided that the institution should discharge the claim for succession duty. The proceeds of the Palmer scholarship might be estimated at £40 per annum.

Owing to the necessity of delivering, in April, the meeting-room to the contractors for the new building, the institution met for the reading and discussion of papers on

Digitized by Google

only 20 evenings during the past session. Exclusive of the president's address, 14 original communications were read and discussed, but the exceptional interest evinced in the debates on some of the subjects brought forward, had resulted in a full amount of material being available for the customary four volumes of *Minutes of Proceedings*. A brief summary was given of the several papers brought under the notice of the members. Reference was also made to the large number of interesting communications selected for printing in Section II. of the publications. For some of these papers awards of medals, or premiums, or both, had been made to Messrs. A. J. Durnston, R.N., J. I. Thornycroft, S. W. Barnaby, W. Duff Bruce, S. J. Berg, C. Butters, E. Smart, J. Richardson, A. Sharp, J. A. Griffiths, A. J. Hill, O. Guttmann, K. Leibbrand, A. Scott, D. Cunningham, and to the representatives of the late H. Gill.

As in the preceding session, 11 supplemental meetings for students had been held, at which papers were read and discussed—some exhibiting sufficient merit to warrant their publication in the *Minutes of Proceedings*. The reports received from Manchester, Glasgow, Birmingham, Newcastle-on-Tyne, and Leeds showed that the associations of students at those centres were continuing to fulfil well the objects for which they were established. The council had awarded Miller prizes to the following students for papers read at the institution and before the local associations: Messrs. W. G. Wales, S. H. Barraclough, E. E. Matheson, A. M. Stewart, R. C. Farrell, and H. Fowler.

The third of the series of "James Forrest" lectures had been delivered, on May 2, by Prof. W. C. Unwin, F.R.S., M.I.C.E., before a full and appreciative meeting.

The completion was announced of the new library catalogue, comprised in three volumes, copies of which would be issued to public libraries and those of educational and scientific bodies in all parts of the world. The new subject index to vols. lix.-cxviii. was in print, and would be issued during the recess.

The council had given considerable attention to the question of enabling all entitled to vote at the annual election to exercise that privilege whether present at the meeting or not. The opinion of counsel was, however, that under the existing charters such votes could only be given personally.

The report finally referred to the operations connected with the rebuilding of the premises, as to the completion of which it was premature at the moment to make a definite statement.

The report having, after full discussion, been adopted, votes of thanks were passed to the president, vice-presidents, and the other members of council for active services in the management of the institution; to the auditors for their care and trouble in examining the accounts, and to the scrutineers of the ballot.

The ballot for council resulted in the election of Sir B. Baker, K.C.M.G., as president; of J. Wolfe Barry, C.B., W. H. Preece, C.B., Sir Douglas Fox, and James Mansergh as vice-presidents; and of W. Anderson, D.C.L., Alex. R. Binnie, W. R. Galbraith, J. H. Greathead, J. C. Hawkshaw, C. Hawksley, Dr. John Hopkinson, Alex. B. W. Kennedy, LL.D., Sir G. L. Molesworth, K.C.I.E., Sir Andrew Noble, K.C.B., Sir E. J. Reed, K.C.B., M.P., W. Shelford, F. W. Webb, Sir W. H. White, K.C.B., and Sir E. Leader Williams.

The session was adjourned to the second Tuesday in November.

The following is a detailed list of the awards made for original communications submitted during the past session:

For Papers Read and Discussed at the Ordinary Meetings.

A George Stephenson Medal and a Telford Premium to Albert John Durston, engineer-in-chief R.N., for his paper on "The Machinery of Warships."

George Stephenson Medals and Telford Premiums to John Isaac Thornycroft,* F.R.S., and Sydney Walker Barnaby,* MM.I.C.E., for their joint paper "Torpedo-Boat Destroyers."

A Telford Medal and a Telford Premium to William Duff Bruce, M.I.C.E., for his paper on "The Kidderpur Docks, Calcutta."

A Telford Medal and a Telford Premium to Sigvard Johnson Berg, A.M.I.C.E., for his account of "The St. Gothard Mountain Railway and the Stanserhorn Cable Railway."

The Manby Premium to Charles Butters and Edgar Smart, A.M.I.C.E., for their joint paper on "Plant for the Extraction of Gold by the Cyanide Process."

A Crampton Prize to John Richardson, of Lincoln, M.I.C.E., for "The Mechanical and Electrical Regulation of Steam-engines."

For Papers Printed in the "Proceedings" without being Discussed.

A Telford Medal and a Telford Premium to Archibald Sharp, Wh.Sc., B.Sc., A.M.I.C.E., for his paper entitled "Circular Wheel Teeth."

A Telford Medal to the representatives of the late Henry Gill,† M.I.C.E., for his paper on "The Filtration of the Müggel Lake Water Supply, Berlin."

A Watt Medal and a Crampton Prize to John Alfred Griffiths, B.Sc., Wh.Sc., A.M.I.C.E., for his paper on "Windmills for Raising Water."

A Watt Medal and a Crampton Prize to Alfred John Hill, Wh.Sc., A.M.I.C.E., for his paper, "Repairs and Renewals of Railway Rolling-stock."

A Telford Premium to Oscar Guttmann, A.M.I.C.E., for his account of "The Removal of the 'Iron Gates' of the River Danube."

A Telford Premium to K. Leibbrand, of Stuttgart, for his paper "On a Concrete Bridge at Munderkingen."

A Telford Premium to Adam Scott, A.M.I.C.E., for his paper entitled "Deep-Water Quays at Newcastle-upon-Tyne."

A Telford Premium to David Cunningham, F.R.S.E., M.I.C.E., for his paper on "The Estuary of the Tay."

For Papers read at the Supplemental Meetings of Students.

A Miller Prize to William Garnys Wales, Stud.Inst.C.E., for his paper entitled "Caissons and Gates for Closing Lock and Dock Entrances."‡

A Miller Prize to Samuel Henry Barraclough, B.E., Stud. Inst.C.E., for the paper, contributed jointly with Lionel S. Marks, B.Sc., entitled "Some Experiments on the Heat Losses to the Cylinder Walls of a Steam-engine."‡

A Miller Prize to Edward Ewing Matheson, Stud.Inst.C.E., for his description of "Timbering in the Ampthill Second Tunnel."‡

For Papers read before Local Associations of Students.

A Miller Prize to Angus Matheson Steward, Stud.Inst.C.E. (of Glasgow), for his account of "The Glasgow District Subway."‡

A Miller Prize to Richard Craig Farrell, Stud.Inst.C.E. (of Glasgow), for his description of "The Permanent Way and Signalling of the Glasgow Central Railway."

A Miller Prize to Henry Fowler, Stud.Inst.C.E. (of Manchester), for his paper on "The Testing and Inspection of Plates.

EXHIBITION OF RAILWAY APPLIANCES AND INVENTIONS.

On Saturday afternoon last Lord Herschell opened at the Imperial Institute an exhibition of railway appliances and inventions. The exhibition, which will remain open till the end of August, is situated in a special building, but the space is somewhat cramped. The idea of the exhibition was first mooted on March 11, and approved of by the council two days afterwards. The new building had then to be erected, and the staff of the institute can be congratulated upon the fact that the exhibition was in perfect readiness on the opening day. There are in all 90 exhibitors.

Messrs. Siemens Bros. and Co., Limited, 12, Queen Anne's-gate, Westminster, show their hydrostatic contact apparatus for railway signalling. The object of the appa-

* Have previously received Watt Medals and Telford Premiums.
† Has previously received a Telford Premium.
‡ It has been determined to print an abstract of this paper in the *Minutes of Proceedings*.

Digitized by Google

ratus is to produce automatically, by the passage of a train, electrical contacts at given points on a railway line, and to utilise such contacts for a variety of train-signalling purposes. The contact apparatus formerly adopted for such purposes usually consisted of one or more levers, which projected from a box fastened to the track, and reached somewhat over the rail. When a train passed this place, its wheels pressed down the levers and produced the desired contact in the box. The great difficulty experienced with such apparatus was the prevention of their destruction by the violent shocks to which they were subjected when a train met them. Somewhat successful improvements have been introduced in providing the contact levers with springs, but even these apparatus cannot be fully protected against external damage. The firm's contact apparatus, it is claimed, entirely overcomes the difficulty of preservation from damage by passing trains, and its extensive and increasing adoption has fully proved its practical value. The apparatus depends upon the bending of a rail, due to the passing of a train or an engine. It needs for its support no exterior points in connection with the ground, and can be made of any desired sensitiveness. The bending of the rail takes place between two fixed points resting on the sleepers. As soon as this portion of the rail is weighted by the wheel of a passing train a very slight movement is obtained by the bending of the rail, which is transferred to the electrical contact by hydrostatic pressure. Among other exhibits of the firm are a guard's van Morse inkwriter; a railway gong alarm, inkwriter, and inductor; telegraph poles showing screw-ring joints, buckle-plate, and pile tube; various insulators and brackets on pole and arms; linemen's tools; two pillars for arc lighting; Siemens's "Band" arc lamps, incandescent lamps, carbons, electric wires and cables; a telephone with siren call; and a set of Obach's dry cells, with a battery testing set of the same.

Messrs. Saxby and Farmer, Limited, Canterbury-road, Kilburn, have on view a full-size apparatus, being a union of the lock and block systems with wrought-iron signal and electric slot and replacer, and improved mercurial rail contacts. They have also an ingenious electric tablet arrangement for working single lines.

Mr. Wilfrid S. Boult, A.M.I.C.E., 60, Castle-street, Liverpool, exhibits a working model of apparatus for signalling passing trains without mechanical contact between the stationary and travelling parts. The method adopted is as follows: On the road are placed a series of permanent or electromagnets producing a magnetic field whose direction of flux is capable of reversal, but in either case transverse to the railway. The field may be continued along the line as far as necessary by employing a suitable number of magnets, all of which may be securely covered in. Carried by the train through the magnetic field is an iron armature, divided in the middle so as to admit of the insertion of a polarised contact-maker, which closes either of two local circuits according to the polarity of the field passed through.

A case of Aylmer-Leclanché, Leclanché-Barbier, and other cells, together with direct-current telephones and bells, and lightning protectors, is exhibited by Mr. R. Aylmer, 47, Victoria-street, S.W.

Messrs. Girdlestone, Tatham, and Co., 16, Davies-street, Berkeley-square, W., are lighting the hall with Andersen's 12-ampere arc lamps of 2,000 c.p. The lamps are fitted with "Holophane" globes, which are made of clear glass and cut in such a way as to distribute the light uniformly in the required direction. The lamps are simple in construction. They are made with large or small globes as required, and for running on continuous or alternating current circuits as required. Portable batteries and lamps, switches, bells and telephones, and fittings, are also to be seen here.

Messrs. McKenzie and Holland exhibit a working model showing three railway block stations, representing the combination of electric and block locking (Sykes's system). They have also an electric train treadle and an electric slot for signals.

Lacombe zinc cells, carbon-headed plates, carbon brushes, and Leclanché cells are included in the exhibits of Le Carbon, 7, Carteret-street, S.W.; and Messrs. Krupka and Jacoby, 15, Queen-street, Cheapside, are represented by Dr. Albert Lessing's dry batteries.

Mr. George Lopes, M.I.C.E., London Bridge Station (L. B. and S. C. Railway), exhibits an automatic electric railway alarm, the object of which is to warn people using level crossings of the approach of a train, and to warn workmen engaged in tunnels and other hazardous places.

Mr. W. Alfred Llewellin, 10, Park-row, Euston-road, Bristol, shows an apparatus by which a signalman, should he in error allow a train to proceed, can automatically place triple detonators in front of the train he has allowed to pass. The apparatus consists of a lead running along the line, this lead being connected with triple detonators throughout the line. Should the signalman accidentally allow a train to pass, he can subsequently cut the lead in his box and the detonators are thereby placed under the wheel of the train. At the same time, the release of the lead causes an electric incandescent lamp to be switched on as a danger signal on the line. Should, between any two sections, a train be derailed, the derailment causes the lead to be cut, placing detonators on the line to warn on-coming trains, at the same time switching on the electric danger lamp and ringing an electric bell in the signal-box. Should a train not derail, but get disabled through various causes, yet be in a perilous position which driver and officials think is or may be detrimental to an on-coming train, and consider that it is essential that the on-coming train upon off line is in some way endangered, the present system is to place fog signals on up and down lines by manual labour if time admits; but under the new system the cut line, as previously described, will perform all the requirements and inform all on-coming trains, all signalmen, block all lines, and give the indispensable light upon the scene.

THE MAGNETIC SURVEY OF THE UNITED KINGDOM.*

BY PROF. A. W. RUCKER, M.A., F.R.S.

The object of the magnetic survey is twofold: firstly, to determine the secular changes in the declination, horizontal force and dip; and, secondly, to investigate the local magnetic disturbances by which these elements may be affected.

In the years 1884-1888 the author and Dr. Thorpe, F.R.S., made magnetic observations at 205 places in the United Kingdom. The results were considered sufficiently interesting to make it desirable that the work should be extended. An allowance from the Government grant in aid of research enabled them to carry out this extension with the help of assistants—Messrs. Briscoe, Gray, and Watson. With the aid of these gentlemen the magnetic constants have now been determined at 882 places in Great Britain and Ireland. The two surveys have been worked up independently so as to give the magnetic condition of the United Kingdom on January 1, 1886, and January 1, 1895. The secular change between these epochs has been calculated, and all the observations have been finally reduced to the later date. By means of the table of secular change it will be possible to determine the normal undisturbed value of the declination at any place in the United Kingdom for some years to come, and by means of a map on which the deviation from the normal values is shown at 882 places it will be possible to gain some idea how far local disturbance is likely to affect the declination at any given place. Similar tables and maps are provided for the other magnetic elements.

As regards local disturbances, it is found that the north pole of the compass is attracted to certain regions and to lines which can be traced for scores or even for hundreds of miles. These lines are called magnetic ridge lines. As a general rule, a region where basaltic rocks appear in large quantities on the surface attracts the north pole of the magnet. On the basalt itself the disturbances are irregular, but an attraction towards it is observed at stations near to but not actually on the magnetic rock. This is very clearly shown in Antrim, in Scotland, between the Forth and the Clyde, and in North Wales.

The ridge lines to which the north pole of the needle is

* Paper read before the Federated Institution of Mining Engineers, May 31, 1895.

Digitized by Google

attracted often run through districts in which the underlying strata are known to be non-magnetic for great depths. The author has, however, measured the magnetic permeability of a large number of specimens of basic rock, and has shown that magnetic disturbances of the magnitude of those observed in the United Kingdom can be accounted for if the surface strata conceal large masses of rock more magnetic than those which exist on the surface.*

For the purposes of the present communication it may be sufficient to select three points for special discussion.

I.—The Relations of the Lines of Disturbance to the Principal Coalfields of the United Kingdom.

These relations are not very simple, and can hardly be explained fully without the aid of the detailed maps now in the hands of the engraver.

Assuming that the positions of the magnetic ridge lines are determined by basaltic rocks, of which portions may or may not appear on the surface, it is probable that where numerous isolated patches of such rocks are visible, they are connected with a vast underground mass by which the needle might be affected at large distances. This is true of the Scotch coalfield. A ridge line runs from the neighbourhood of North Berwick to the Clyde between Glasgow and Hamilton, then turns south to Newmilns, and finally runs in a northerly direction towards Ardrossan and Cumbræ.

In the Northumbrian and the northern part of the Durham coalfield the magnetic disturbing forces are feeble, and are directed to the north and east. In the southern part of the Durham coalfield the influence of the great Yorkshire and Lincolnshire ridge line is felt, so that the disturbing forces are directed southwards.

The Yorkshire coalfield is dominated by a ridge line which runs south-west from Harrogate towards Keighley, and follows, or nearly follows, the outcrop of the millstone grit as far south as Matlock. The general tendency of the magnet in this region is therefore to deviate to the west.

In the southern part of the Derbyshire coalfield the north pole of the magnet is attracted from all sides to a centre which is a little to the north and east of Nottingham. The magnetic disturbances in the Lancashire coalfield are feeble, but on the whole the evidence bears out the conclusion that a ridge line runs from Rochdale to Wigan and Southport. This line, and that which roughly coincides with the Pennine range, are interesting examples of the fact that, when we are dealing with strata not later than the carboniferous rocks, lines of magnetic attraction are generally associated with lines of geological upheaval. If the cause of the magnetic attraction is the magnetisation of deep-seated magnetic rocks by the inductive influence of the earth's field, this would prove that the forms of the older surface rocks tend to follow the slopes of hidden magnetic masses. No such relation is observed in the case of strata deposited later than the carboniferous era. From the point of view of the magnetician the South Wales coalfield is divided into two parts by the River Taff, which runs into the sea at Cardiff. East of this boundary the magnet is strongly attracted to a centre which lies near Risca or the southern end of the Ebbw Vale. West of the Taff an important ridge line which runs across England, from Deal to Haverfordwest, passes from Brecon to Neath, and thence nearly due west through the centre of the coal measures.

The magnetic constitution of the South Staffordshire and Warwickshire coal districts is very interesting. The coal measures there appear as islands of old rocks surrounded by newer deposits. A curious horseshoe-shaped ridge line runs from the one to the other—from Bromsgrove round Birmingham to Kenilworth, then passes southward *vid* Kenilworth to Reading, and finally enters the English Channel at Chichester. It has been traced by M. Moureaux through France from the neighbourhood of Dieppe to the south of Paris.

These are perhaps the most noticeable points in the magnetic constitution of the coal-bearing districts of the United Kingdom. They do not give any countenance to the view that the magnet can be used for the discovery of coal. They do afford information as to the directions of the deviations from the normal magnetic meridian which are to be expected in the different parts of our principal coalfields.

It must, however, be remembered that the deviations are comparatively small, rarely amounting to as much as a degree, and that no magnetic map can indicate the much greater disturbances which may be produced by the immediate neighbourhood of a small magnetic rock, the effects of which would be inappreciable a few yards off. This brings us to the second part—viz.:

II.—The Distance from Masses of Basalt at which the Deviation produced by them on the Magnet would be Inappreciable.

Magnetic rocks are often permanently magnetised, and may deflect a compass held close to them through 40deg. or 50deg. The permanent magnetisation is, however, irregular, and at a comparatively short distance the disturbing effect appears to be due rather to the uniform magnetisation produced by the earth's magnetic field.

The author has made calculations on this point, based on the measurements of the magnetic properties of basalts above referred to, and during the magnetic survey special observations were made near isolated and prominent masses of trap. The general conclusions, both of theory and experiment, are (*a*) that dykes and thin uniform basaltic sheets produce no measurable effects except at distances from their edges, which are small multiples of their thickness; (*b*) that isolated masses of trap-rock a few square miles in area produce no important magnetic effects at distances comparable with their linear dimensions.

Of course, isolated cases may, and probably do, occur where one or other of these indications would be incorrect. They hold good in every case which has been specially investigated in the United Kingdom, such as the Island of Canna, near Skye, Boulmer Dyke, in Northumberland, Titterstone Clee Hill, in Shropshire, and Brent Tor, in Devonshire.

The last point on which a few words may be useful is—

III.—The Effects of Geological Faults on the Compass.

The view commonly held that faults affect the needle may in some cases have some foundation in fact. A line of magnetic attraction coincides very closely with the great fault marked by the Caledonian Canal. But though it is possible that magnetic rocks may lie nearer to the surface on one side of a fault than on the other, and that thus a magnetic disturbance may be produced, such an effect will be very small except under favourable conditions. If the throw of the fault is small compared with the depth at which the magnetic rocks occur, the compass needle will not be affected.

It is hoped that, apart from the purely scientific interest of the determination of the positions of the lines and regions which attract the north pole of the magnet, such facts and generalisations as those above indicated may be of some practical use.

* *Proceedings*, Royal Society, vol. xlvii., p. 505. 1890.

Electrolytical Process of Bleaching.—In a recent review on progress in bleaching in *Lehne's Färberzeitung*, Dr. Kielmeyer mentions an electrolytical process invented by Dr. Karl Kellner, which, whatever be its practical value, has at least the merit of being original. The necessary apparatus consists of a pair of rollers—the one iron, the other carbon—which, while rotating, are fed with an electric current by contact with wire brushes, and thus converted into the two poles of a battery. The cotton cloth before passing these rollers is saturated with brine and runs in company with an endless felt blanket, also saturated with brine, which is next to the iron roller and receives the caustic soda formed, to deliver it further on into a tank filled with salt water. The chlorine liberated at the carbon roller accumulates in the cotton fabric. On issuing from between the rollers (whereof there may be several pairs) the cloth remains rolled up for some time before it is washed to prolong the bleaching process. Whether the process has already found practical application does not appear.

THE COUNCIL OF THE INSTITUTION.

The proper constitution of the Council of the Institution is one of the most complex problems with which its members have to deal. The session is now practically at an end, and one of the first duties of the Council in the autumn will be to prepare a house list—that is, a list of those members of Council whose term of office expires, and the names of those members of the Institution the Council suggest are best to fill the vacancies.

Now, in the first place, we want to point out that the Institution is not an advertising medium for cheeky commercial travellers and representatives of thirtieth-rate firms. There has been and is far too much of this kind of thing in our Institution. The men who guide the Institution are for the most part men of ability, men who have done something to educate and enlighten the profession and raise its status. The residuum are men who have no earthly right ever to have been elected, and ought never to have had their names upon the house list. Let the members look over the names and ask themselves the questions, What has this or that man done to benefit the profession generally? What papers has he written, what information has he given? Why, the very names of some stink in the nostrils of the more eminent members of the profession, and are representative of all that it is desirable to avoid. There is no necessity to elect one representative of a dozen firms who hang out the sign of "Electrical wants supplied." Fancy the Institution of Civil Engineers doing such a thing! No; there the claims of the candidates are carefully weighed, and unless of a calibre above the average standard it is hopeless to expect selection.

Some years ago it will be remembered the house list of the Council contained extra names, so that the voters could select from amongst them whom they desired to see upon the Council. This plan was found to be more or less unworkable, more we think from a phase of human nature which is rather to be commended than disparaged. All men, if they have any real grit in them, have also a vein of conceit. They do not like the idea of being candidates for a position and failing to obtain that position. Then, again, modesty is not necessarily absent from conceit, and the able man may have so lived and acted that his abilities are known to only a limited circle. If the house list is to be restricted to the exact number of the Council, it is the duty of the Council to examine the credentials of every name brought before them in the most careful manner, and to avoid accepting the name of any man who is run by an energetic clique. It is well known that individuals do court a seat on the Council—and such a seat is an honourable position; yet the system of log-rolling is not one likely to redound to the credit of the Institution. "You push me in this year and I will do the same for you next year," is not the policy of an institution which in importance and numbers should rank second only to the Institution of Civil Engineers.

The Council is nothing if not representative. This we endorse, but disagree as to the sections to be represented. We do not want representative

Digitized by Google

tradesmen, if we do of manufacturers. There will be no elevation of the status of the profession by selecting men whose home is the shop, and whose experience is limited to the sending in of tenders and the making out of invoices. Neither do we want representatives from among that numerous body who call themselves consulting engineers without having undergone any real training for the work. The issuing of an open specification does not stamp the consulting engineer as having ability, originality, or, indeed, any views of his own at all, except a 5 per cent.—or less, if he is hankering after work—commission. We distinctly say there are consulting engineers and consulting engineers. One body consists of men of repute, of knowledge, ability, and experience; the other of men who have hung out a sign—and that is all.

It is useless to criticise when the house list is published, hence these early remarks upon a subject that is of the greatest importance to the profession. The Council is certain to encounter strong opposition if it continues its course of, say, last year, and one of the things to be avoided is the creation of an energetic opposition among the members as a body.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

DUBLIN TRAMWAYS.

SIR,—I have read your leader-writer's reply and Mr. Sellon's letter, and am sorry you should consider my previous letter discourteous. I had no such intention, but I had a feeling that you were not dealing with the question in your usual impartial manner. Are you now quite fair in stating, without giving one figure in support, "that economical and efficient operation can be best secured by a trolley wire over the centre of the car roof"?

After reading Mr. Sellon's letter, I felt constrained to say—

"Ye gods, it doth amaze me!
A thing of such a feeble temper
Should so get the start of the majestic world,
And bear the palm alone."

I do not see why I should satisfy the curiosity of Mr. Sellon, but I am quite willing to do so when he has told us who and what he is. Has he ever constructed an electric tramway? Has he ever worked an electric tramway? Has he ever had one single day's practical experience of an electric tramway?

I hope I shall not be again accused of discourtesy when I say that I have in my time read many wordy letters, but in a discussion of this kind what is wanted are facts, and I suggest to Mr. Sellon that neither in theory nor in fact can he prove that there is any less mechanical efficiency in the system as at work in South Staffordshire than in the American system.

When Mr. Sellon suggests that the adoption of the principle of the South Staffordshire system for Sackville-street would necessitate a trolley arm 40ft. to 50ft. long, he displays his ignorance of the system. One of the objects of "Dickenson's system" is to avoid the necessity of the trolley wire following the curvature of the track, and this object would be attained if the supports for the trolley wire were between the tracks.

I suggest that Mr. Sellon is quite mistaken as to an extension of the span-wire system in Leeds. Will he kindly quote his authority?—Yours, etc.,

JAMES L. OWEN.

120, Colmore-row, Birmingham.

ELECTRIC ORGANS.

The fundamental principle by which an organ or a piano can be worked electrically at a distance from the keyboard has been known for years. Any student of elementary electromagnetics will readily devise rude means for accomplishing what is necessary to this end. There are, however, in the problem many difficulties practically when working large organs electrically, and great honour is due to Mr. R. Hope Jones for the care and time which he has devoted to the subject during the last 10 years. We were recently permitted to view the four manual organ installed by him in St. George's Church, Hanover-square. The electrical problems dealt with and successfully solved in this organ enable the organist to have a control over his instrument hitherto undreamt of. The touch required is extremely light, and the stops and couplers, although very numerous, are, by reason of their small size, extremely accessible and easy to work. The console, or key-desk, is placed in the chancel, and the organ is at the further end of the church in the gallery. The connection between the two is effected by means of a cable containing some 18,000 wires, but these are of such a small gauge that the outside diameter of the cable is only 1½in. One wire is required for each pipe. The actuating electromagnet is an exceedingly well-made piece of apparatus. It is made of about ⅛in. diameter iron bent into the form of a long horseshoe. The two poles are let into a small zinc plate, on which are the guides for the armature disc; this is a small disc of iron about the size of a threepenny-piece. In the ordinary condition it is held away from the poles by air pressure. When attracted it operates a small air-port, and disturbs the balance of the pneumatic relay, which opens the organ pipes to the wind pressure. Mr. Hope Jones claims that the zinc plates touching the iron poles protects them electrolytically from the oxidising action of the atmosphere. So little current is required that three Hellesen dry batteries are sufficient to work the organ for months.

The description of the advantages of the various couplers and combination of stops, which can be arranged beforehand on the key-desk at St. George's, would be unintelligible to anyone but an organist. We were, however, impressed with the fact that the electric organ facilitated all the operations previously possible on organs, and gave many new advantages. Still, we hope that the inventive genius of Mr. Hope Jones will not act prejudicially to the interest of the organists themselves, although we see no reason why in the near future one organist should not supply the music to the whole of the churches in London from one keyboard. The question of the time taken by the rest of the service not being quite uniform, would be the only objection. The inventor of this most admirable system is now devoting his attention to the production of sound in organ pipes by means other than wind pressure. None of these methods have so far been used at St. George's Church, but we understand that one is shortly to be tried there. It consists of an ordinary organ pipe with a flexible diaphragm at the bottom. From the centre of this a string will be hung, which is electrically pulled against a revolving resinned cylinder. The vibration will thus be imparted in the same manner as in a violin.

SOME PHYSIOLOGICAL EFFECTS EXPERIENCED IN CONTACT WITH LIVE ALTERNATING-CURRENT CIRCUITS.*

BY LUDWIG GUTMANN.

Since one of the topics of the day is the effect of the electric current, and especially alternating current, on the human body, it may be of interest to throw some further light on this question, and on those unfortunate beings who find themselves unintentionally or otherwise in the grasp of this mystic power. So far, no one who survived has satisfactorily explained his feelings, and it might be supposed erroneously that everybody would be unconscious as soon as he had established connections with a live circuit.

Having had a number of men under me doing work on such circuits, I have tried to find out from those who have experienced severe shocks what they had felt, but received replies from which no logical conclusions could be derived, with one exception—namely, regarding the length of time they believed they were in the circuit. I have found invariably that men caught on alternating-current circuits would estimate the length of time of contact a great deal longer than could be accounted for, and their statements have been contradicted and disproved by others near at hand at the time of the accident. A man who had formed part of a circuit would say he believed he was in circuit for 10 minutes, when the whole time may not have been more than as many seconds, or at the outside half a minute, as learned from the statement of others.

While trying to unravel this mystery, which I began to think was not intended to be known to man, the means of acquiring the information were accidently placed in my way. It happened this way. My experimental room was located on the first floor of the factory and divided from the main part in which light machine-work was done, by a low partition. There are some 40 or 50 men engaged on this floor, filing, hammering, fitting, turning, etc. The dynamo utilised for testing was on the ground floor, and the switch controlling this, a special circuit, temporarily arranged and brought to my room, was between my room and the transformer test-room. Having finished some determinations regarding a new type of transformer, I went out and opened the switch and returned to my room. Then I carelessly opened the connectors, not expecting that on my return to the room somebody else would close the switch again, which proved to be the case in this instance. On getting hold of the primary wire of the transformer with one hand and the circuit wire with the other and pulling them out apart from the connectors, I placed myself directly in the high-tension circuit. I was caught, the bare ends of the wire were held one in either hand, which, by the flow of current were closed, holding the wire, a No. 8 or 10 B. & S., tightly in the hands. For an instant I was stunned; when this momentary unconsciousness passed away I found myself unable to breathe, utter a cry for assistance, or move. I was spellbound in a crouching position. The noise around me in the shop seemed to be very weak; it was as if I was a block or more away, and the hammer blows, which generally made the shop so noisy, were very faint. I was not capable of thinking about myself and the danger in which I was placed. All I do remember besides the faint hammering was that I felt my arms shaken as if in the grasp of some powerful man in a playfully exaggerated hand-shake. I felt the rolling action of the current impulses as they slowly approached, just as we observe the heavy waves approaching the shore on the beach. Suddenly, the wires had burned through the skin, and in some way did not make proper contact. The current was momentarily interrupted, and I jumped up, or as this motion was a passive one on my part I was straightened out from my bent position by the relaxation of the muscles, while in doing so the dangerous wires dropped to the floor. I was free once more, and after taking a deep breath I felt a glowing heat all over my body and a weakness in the limbs, just as after a fainting spell. In spite of this trouble, which had not been noticed by anybody, I continued to work, feeling ashamed of having been caught in that way. The dynamo was a 10-pole alternator, yielding at the time 1,100 to 1,150 volts while my body was in series with the primary coil across the terminals of the generator.

With this unexpected experience at my disposal I have been able to explain a number of sensations. Of course, I must admit that the current was weak enough and the conditions favourable enough (for me) to recollect, but I believe that it was very near the limit. I could neither breathe, utter a sound, move, nor was I capable of thinking anything except the sensation to which I was subjected, as no other thoughts, not even fear for my life, or knowledge of my predicament, entered my mind at any time. All such ideas must have been dormant. This experience occupied my mind in my leisure moments, and I asked myself: Could you not have counted the alternations had you thought of it, especially as every impulse seemed so clear and distinct, such a slow rolling motion, starting in the hands and creeping up the arms, with such a long time apparently between the waves?

At first I thought I could have done it, but later I came to the conclusion that to experience and feel every impulse distinctly is one thing, and to remember, record, or integrate is an entirely different thing, leaving out of consideration the fact that the concentration or retention of such a thought of counting or attempting to count would be a questionable, if not an impossible, task under the influence of the current.

We can understand why some people think the sensation is like that of being beaten, or why I felt the severe hand and arm shaking. It is simply the result of the current on the muscles which alternately assume a state of contraction and relaxation. The strange fact that men believed to have being in circuit a considerably longer time than was actually the case can now also be accounted for; evidently, if you can clearly distinguish every impulse, the brain must be capable of counting 16,000 in a minute, even if we are not able to mechanically record it. Under these conditions a quarter of a minute would mean counting mentally to 4,000, and any man would naturally think the time must be more than five minutes.

The very fact that men have made such statements with the error in the same direction clearly shows that they were not unconscious, but that some part of their brain was temporarily disabled or paralysed.

Dr. Goelet's conclusions, derived from the examination of the body of the murderer Hampton at Sing Sing, and published in the *Electrical World* of March 16, are very logical. They should, however, not be used in a general way. There is a vast difference between an accidental contact with a live wire and especially prepared connections for executing criminals. His conclusion, however, that death is painless because "electricity travels faster than the nerves can transmit painful impulses" seems to me erroneous, believing that three times the number of alternations as used at present can still be clearly distinguished by the brain.

Death may be instantaneous if a large amount of energy is suddenly discharged through the body; it can be painless also when the apparatus is less powerful and properly applied; because a sufficient amount of energy used, while it may not cause instant death, will produce contraction or expansion of parts of the brain either by direct action of the current, or more probably by the pressure of the blood vessels on the surrounding portions of the brain, causing instantaneous unconsciousness, while death results ultimately from the decomposition of the blood; or, as these investigations have also disclosed, by the bursting of blood vessels in the brain with their well-known effects.

The statements made by Prof. D'Arsonval have proved to be incorrect as regards the executions in New York State, yet the controversy he has caused has been of incalculable value, for it has been the cause, first, of establishing the truth, and, secondly, to restore to life those or many of those who accidentally have fallen into the grasp of this invisible force. It is gratifying to know that, owing to just these controversies and the resultant instructions given, a number of hapless victims have been restored to life by artificial respiration.

THE MECHANICAL PRINCIPLES OF ELECTRICAL ENGINEERING.*

I fear my address must be commenced with an apology. When I was invited to come here to-night, I had no idea of either the size of the audience it would be my duty to address, or of the magnitude of the subject I should be expected to deal with. If, therefore, this lecture is to some tedious or elementary in its character, I trust you will bear with me for the sake of the few whose technical knowledge may not have reached an advanced stage.

The relation of mechanical to electrical engineering is so close that I have found considerable difficulty in dealing with those branches of our subject verging on the borderland of the two allied sciences and classifying them as belonging distinctly to either. This must always be so, and I fear it is the one of all others that becomes the *pons asinorum* to those who at the outset of their career are called on to take charge of or erect any important work belonging to either. At the present day there is hardly a single operation of any magnitude conducted of mainly a mechanical or electrical description that does not also entail at least a rudimentary acquaintance with the elements of electrical or mechanical science respectively. Our knowledge at the present time is vast, rapidly extending, yet nevertheless so infinitely incomplete, that it cannot now be said, as once it was, that a man should know something of everything and everything about something. I do not think that it is asking too much of our electrical engineers to pay adequate attention to the principles of the mechanical side. I have no hesitation whatever in asserting that not only has everyone of our leading electrical engineers attached this aspect of the question with assiduity, but that also the extraordinary relapses in the progress of electricity in the seventies were due largely to the non-acquaintance of such knowledge by those engaged in its pursuit. The fundamental axiom of mechanical science is the same as for any other—namely, accuracy. The cultivation of judicial reasoning, powers of drawing logical conclusions, of making careful measurements, experimental work, and of handicraft, forms the basis of the education of the mechanical engineer, as it should of the electrical engineer. You are, of course, acquainted with the admirable work done to encourage such advancement in this training school, and such work is to a great extent common to that done in our great mechanical laboratories, and it merely becomes a question of diverting the existing powers that your students must already possess into suitable channels to produce a combination of electrical and mechanical knowledge before which many of our greatest difficulties are overcome. Take, for instance, the question of strength of materials. Iron (cast and wrought), steel, copper, gunmetal, and other alloys, each have their peculiar individual properties, which must be understood and appreciated before they can severally be put to the most efficient service. It may be said that the ubiquitous pocket "Molesworth" can supply this knowledge, but the distinguished author of this valuable little work would not for a moment pretend that it should replace the training of the student, and, in fact, it would be as dangerous in the hands of such a one as would be the "British Pharmacopœia" in the restless hands of the chairman of the London County Council. The student must be trained how and when to apply the formulæ and constants supplied in text-books, and such information is as vital in the design of a dynamo as it is in that of a steam engine or boiler. To obtain such training there is only one royal road, and that is by actual study of the subject from the theoretical as well as the experimental aspect.

I have referred to the question of material as of importance, and as an example I will give you a general outline of the various forms and properties possessed by iron and its commoner compounds. Pure iron is unknown to the engineer, and what is generally called iron is classified into five main groups, distinguished the one from the other by the physical properties and chemical constituents. These five classes of iron compounds are often referred to as (1) weld iron; (2) weld steel; (3) ingot iron; (4) ingot steel; (5) pig iron. (1) Weld or wrought iron will not sensibly harden and temper, can be forged and welded, contains 0·0 to 0 6 per cent. carbon, and is manufactured from any forms of iron not in a fluid state. (2) Weld steel, or puddled steel, is distinguished from weld iron, insomuch as it will harden and temper and contains 0·6 to 3·0 per cent. carbon. (3) Ingot iron differs from weld iron, insomuch as it has been cast from a fluid state into malleable masses; carbon, 0·0 to 0·6 per cent. (4) Ingot steel is also cast from the fluid state, will temper on quenching, and contains 0·6 to 3 0 per cent. carbon. (5) Pig iron is cast from fluid state in two forms—namely, white and grey—containing amorphic carbon only, or with graphite to the extent of 5 or 6 per cent., and frequently 5 per cent. of silicon manganese sulphur in addition. It is brittle, and cannot be welded or tempered.

From the foregoing notes it may have been observed that steel is merely an impure form of iron, which, in consequence of the presence of the other elements, has the property of hardening on being quenched; and although the main impurity is very frequently carbon, this is not always so, since iron alloys of tungsten, chromium, titanium, manganese, etc., exist, and the alloy or mixture is still called steel. The proportion and nature of even a minute impurity influences the useful properties of steel enormously. For instance, for boilers, ship plates, girder plates, etc., a steel containing 0·05 to 2·0 carbon is commonly used, having tensile strength 25 to 32 tons per square inch, extension 20 to 27 per cent.; for making railway axles, tyres, rails, guns, and heavily-stressed parts, a steel containing 0 2 to 0·35 per cent. carbon, standing 32 to 38 tons per square inch, and with an extension 15 to 20 per cent. For springs, guide-bars of engines, and pieces subject to friction, such as shafts, steel is used containing 0·35 to 0·5 carbon, tensile strength 38 to 46 tons per square inch, extension 15 to 20 per cent. in 8in. Or, again, for tools, as much as 0·5 to 0·6 per cent. carbon is used, and in this case the tensile stress equals 46 to 51 tons, but the extension is only 5 to 10 per cent. It is also a matter of importance to know that permanent magnets are made of the hardest tool steel, whereas the purest soft wrought iron has the greater permeability, and the conductivity of the latter is also slightly greater than steel, being about 15 to 20 per cent. of that of copper. Although the apparent difference between tool steels and pure wrought iron is merely due to the presence of about 0·5 per cent. carbon, the latter may stand more than twice the ultimate breaking load of the former.

In comparing the results of tests with the chemical constitution of the material, it will be found that, in general, elements which increase the tenacity will also decrease ductility and resilience. Thus, carbon increases strength up to a limit beyond which an excess begins to weaken it, as at the limit which separates steel from cast iron, but every addition of strength takes place at the sacrifice of that ductility which is an essential property of good iron. Phosphorus adds strength, as do manganese and other less common constituents, but in most cases a limit to increasing strength is reached, and is accompanied by a noticeable loss of ductility. It sometimes happens that the elastic resilience increases with addition of such elements up to a limit, which limit is, however, reached usually long before the increase of strength ceases.

I have dwelt at some length on the properties of one single common material of construction for no other purpose than to show how essentially divergent such properties are, even in substantially one material under different conditions. It is obvious from this that the uses to which the various forms can be put must be totally variant, and, therefore, it behoves the electrical engineer to be acquainted with the properties, and to know how to test the material to ensure that when he has ordered a given quality he is getting what is requisite. The following is the test for Hadfield's manganese steel (10 per cent. manganese). Test piece forged and quenched, not turned. Usually 1 per cent. manganese makes steel useless for constructive purposes, but with 10 per cent. the alloy is too hard for

* An address delivered to the students at the Croydon County Polytechnic by Mr. H. B. Ransom, A.M.I.C.E.

Digitized by Google

filing, is very ductile, and as strong in tension as the best crucible steel. It apparently does not exist in a state of ease, for a permanent set begins almost at once on testing. The specimen was 10in. long and 0·855in. in diameter. The limit of elasticity 60,000lb. = 26·8 tons, so that the extension = 0·07in., or $35{\cdot}5\frac{1}{1000}$in. At 120,000lb. stress the strain = 2·66in., and was still unbroken; in fact, the testing machine then broke. A remarkably good iron tested under similar conditions had its limit at 16·05 tons, with extension of $19\frac{1}{1000}$in., and broke at 39·1 tons per square inch fractured area, or 24·5 tons per square inch original area, with a total extension of 2·356in. Thus manganese steel is an exception to the general rule, inasmuch as its tenacity exceeds that of best crucible steel, and its elasticity and ductility exceed that of wrought iron. The proportion of foreign matter present in its composition is so large, however, as to make doubtful whether it ought to be included in the list of steels.

The testing machines in which these strength of material experiments are made are simply modifications of the ordinary steelyard weighing-machines, in which the load applied to the test piece is equivalent to the cartload of coal to be weighed, and the test piece is arranged so as to act merely as a link connecting the weighbridge with the steelyard. The load is commonly applied by means of an hydraulic ram and an accumulator, so as to regulate easily and to a nicety the stress on the test piece. By very trifling modifications, it is easy to see how the same machine can be used for testing the strength of materials as beams, or in compression, as well as in tension. For tensional experiments, it is preferable to use a separate machine which may be of much simpler construction. There are a considerable number of designs for testing machines, and something of the sort is usually considered to be an almost indispensable adjunct to an engineering laboratory. Among others, may be mentioned that of Mr. A. H. Emery, designed for the United States Board appointed to test materials for their navy. This machine can test specimens from 1ft. to 30ft. long and 30in. wide, and on trial before acceptance was tested as follows: A hard wrought-iron link 5in. was slowly strained in tension, and broke at 722,800lb. A horse-hair was next tested $\frac{7}{1000}$in. diameter; it stretched 30 per cent., and broke at 1lb. Other machines have been designed by Wicksteed, Greenwood and Batley, Kirkaldy, Thurston, etc., and in most of these, if not all, stresses of 100,000lb. may be measured to a pound or so. The extension, contraction, or deflection of a test is measured by a separate gear attached to the test piece itself, and is usually capable of detecting and, if need be, recording changes of form of $\frac{1}{1000}$in. It is, of course, equally important to take the dimensions of the test piece before and after testing, and for this purpose various little instruments depending on the vernier for accuracy have been devised which may generally be relied on to the $\frac{1}{1000}$in. also.

The points to be noticed on the stress-strain diagrams are: stress = molecular resistance to disruption under application of external load, measured in pounds per square inch area; strain = distortion due to external load, measured usually in $\frac{1}{1000}$in.; specific extension or compression = mean extension in $\frac{1}{1000}$in. for 1,000lb. stress. Limit of elasticity is reached under minimum load so great as to prevent the return of test piece to original form on removal of load. Each material has clearly defined limit, specific extension, and modulus. Another feature of iron under stress is that it cools on being strained under its limit, and heats on being strained over its limit; *vice versâ*, on being released below its limit it heats. This may be readily ascertained by simple electrical experiments, using thermopile and galvanometer, and tells us that there is no molecular friction below limit and there is above the limit.

The three forms of stress are tensile, compressive, and shearing. Bars in tension, or ties, are in a state of stable equilibrium—that is to say, if bent, tension would tend to restore the bar; but the contrary is true with struts. Although compressive stress is mathematically merely equivalent to negative tensile stress, the effect on the material is very different. For instance, the stress in a tie is almost independent of its length; but length is a very important factor in the construction of struts. Again, the mode in which a strut is held at the ends influences its resistance to buckling enormously. Shearing stress is produced by the action of two equal and opposite couples, and its effect is to slide one molecule over another. The stress per square inch may be uniform over a given section, or variable; the latter case occurs in beams and shafts. The strength of beams does not necessarily vary as the area, but the stress on any small area is proportional to the area multiplied by its distance from the neutral line. It was found by Hooke that stress was proportional to strain up to a certain point, and therefore one may expect that a stress-strain diagram will be for some distance a straight line. Hooke's law is only true below the limit of elasticity, and then only when stresses are gradually increased. Cast iron is peculiar in its behaviour in tension; it often stretches twice as much as wrought iron for same load, and then suddenly breaks with none of the usual intermediate stages. Materials are always designed to carry loads beneath the elastic limit, and, therefore, for purposes of calculation we can assume Hooke's law to be true. For tension, let spec. stretch = e = stretch in $\frac{1}{1000}$in. in a bar 10in. long, under a stress of 1,000lb. per square inch.

For wrought iron $e = 0{\cdot}3$ to $0{\cdot}33$, cast iron $e = 0{\cdot}7$ to $0{\cdot}8$.

Let x = extension in inches in a length of l inches under a stress of s pounds per square inch.

Then $$e = (x \times 1{,}000) \times \frac{1{,}000}{s} \times \frac{10}{l} = 10^7 \frac{x}{sl}.$$

As e is constant for a given material, then $\frac{x}{sl}$ is constant,

and $\therefore \frac{sl}{x}$ is constant. $\frac{sl}{x} = \mathrm{E} =$ Young's modulus.

$$e = \frac{10^7}{\mathrm{E}}, \text{ or } \frac{\mathrm{E}}{s} = \frac{l}{x};$$

and $\therefore$ if $\mathrm{E} = s$, then $l = x$.

$\therefore$ E = stress in pounds per square inch,

which would double original length of a bar following Hooke's law.

Young's stretch modulus is a figure of great importance used in calculations relating to beams, arched ribs; and from a number of experiments I have made it varies from

7,500,000 to 15,000,000 for cast iron.
25,000,000 to 30,000,000 for wrought iron.
25,000,000 to 32,000,000 for steel.
12,000,000 to 14,000,000 for gunmetal.
12,500,000 to 17,000,000 for copper.

Fractures are often taken as indicating good or bad iron, but they are very deceptive and vary enormously in appearance according to the precise way in which the metal is broken.

Repeated loading as a mode of test is useful in the extreme, but comparatively little is known about it. In Wohler and Spangenberg's experiments, the wrought-iron test piece broke at 48,000lb. per square inch, and was tested by rotating with heavy load at one end. Rupture may be caused, not only by a steady load which exceeds the carrying power of a material, but also by repeated applications of stresses, none of which are equal to the carrying strength. The differences of these stresses are measures of the disturbance of the continuity, in so far as by their increase the maximum stress which is still necessary for rupture diminishes. For struts 30 or 40 diameters in length buckling occurs at definite points, but if the ratio $\frac{l}{d} = \frac{80}{1}$, or $\frac{100}{1}$, the strut buckles at very low loads. In the latter case the strut strength is in independent of strength of material, but is proportional, other things being equal, to its modulus of elasticity. For short struts the resistance to buckling depends on distance between points of contrary flexure. The problems relating to beams are too complex to be dealt with in a few minutes, and I will therefore leave the question concerning strength of materials and pass on to one which is no less interesting—namely, motive-power generation; but before so doing I may be allowed to express a hope that my words have been sufficient to show young electrical students that materials such as iron cannot be safely used in ignorance of all their properties.

To generate electricity on a large scale, it is at present essential that the electric generator should receive, in the first place, its motive power from some source not directly involving the use of electricity. This may be done by steam engines and boilers, or refuse destructors, gas-engines using town's gas or producer gas, turbines driven by water power. To Rumford, Joule, and others should be given the credit of having first established and defined the relations between electrical energy and mechanical energy, and also between mechanical energy and heat energy. The historical experiments of the paddle-wheel and falling weight, culminating in the mechanical equivalent of heat called Joule's equivalent (J = 772 foot-pounds = 1 thermal unit) must be familiar to all. Heat and mechanical energy are mutually convertible, and heat requires for its production, and produces by its disappearance, mechanical energy in the proportion of 772 foot-pounds per British thermal unit. It is interesting to note that although Joule was the first to bring this figure into prominence, Carnot published in 1824 a work entitled "Reflexions sur la Puissance Moteur de Feu," in which he arrived at the conclusion that heat and mechanical energy were convertible, and had actually obtained a correct value of the mechanical equivalent of heat, whereas Joule's second series of experiments were only published in *Philosophical Transactions*, 1848-1850, and British Association, 1867. Although 772 foot-pounds is commonly taken as the value of J, the time cannot be far distant before this figure must be revised. Joule himself showed by later experiments with electrical apparatus that 782 was more accurate, and subsequent observers have fixed it at about 780. The electrical experiments of Joule are interesting, as forming a connecting link between electrical energy and heat energy, from which has been derived the equation 1,000 watts = $1\frac{1}{3}$ h.p.

The relation between heat, work, and electricity being established, we have next to consider the manner in which such transformations of energy are accomplished. Assuming for the moment that heat is contained in a gas, how is that heat going to be practically converted into foot-pounds? In the first place, this problem cannot always be solved at all, and in all cases the efficiency is very low. For instance, the thermo-dynamic efficiency may be only ·08, and the mechanical efficiency 0·5, leaving a combined efficiency of $3\frac{1}{2}$ per cent. Theoretically, all the heat should be received at one temperature, T_1, and rejected at one temperature, T_2. The temperature being a measure of the heat contained in a given body of known weight, the thermo-dynamic efficiency is $\frac{T_1 - T_2}{T_1}$. But T_1 T_2 must be measured in absolute temperature—*i.e.*, deg. F. + 461deg.

In the case of a steam engine and boiler the water is received at 60deg. F., say, and is raised to 360deg. F., receiving heat the whole time, the greater part during its conversion from water to steam at constant temperature. Again, only a portion of the heat contained in the steam can be converted into work, because the water cannot be reduced to a temperature of absolute zero. Although steam-engines have been mentioned, there is no difference in principle between steam and air or gas engines. In the steam-engine the working fluid starts as a liquid occupying a small volume, is converted into a gas occupying a very large volume, and, lastly, is changed into a liquid again, whereas in an air-engine the working fluid remains always gaseous and occupies a large volume. The advantage of air or gas engines lies in the fact, that in dealing with air or gas the pressure is not necessarily a function of the temperature. Hence, the theoretical efficiency, $\frac{T_1 - T_2}{T_1}$, may be very great because T_1 may be very great and T_2 small. An air-engine may have a theoretical efficiency of 0·75, but its actual efficiency may be only 0·1, because the difficulty of getting metals to stand at 3,000deg. F. or more is obviously great. A steam-engine may have a theoretical efficiency of only 10·3, but its actual efficiency will perhaps be 0·2. There are certain obvious advantages in connection with gas-engines which make them very attractive. Gas is far more easily oxidised than coal, and the boiler and steam-engine cylinder being rolled into one cylinder, so to speak, the convenience of the combination is great. The difficulties of gas-engine manufacturers are being overcome, and at the present time the Belfast Corporation have completed an electric light installation in which the engines receive their motive power entirely from gas.

I do not propose now to dwell on the relative merits of steam and gas propulsion, but would prefer to describe the ways and means by which the commonest source of motive power—namely, the steam engine and boiler—may be properly tested. I take this because it does not fall strictly within the province of the electrical engineer to design the engines, but it frequently becomes his duty to test the efficiency of the motive-power plant under his control. Steam-engine testing must be treated apart from boiler testing; for the latter is tested by the coal it consumes and the water it evaporates, whereas the other is efficient or otherwise according to the steam consumed per unit of work done. To find the heat received by the engine, the amount of water which the engine receives as steam must be measured, and the amount of heat which it has received calculated. This may be done in several ways. The feed water passed into boiler may be weighed, the temperature of evaporation is given by the pressure gauge, and the temperature of feed found by ordinary thermometer. Of course, the water level and steam pressure in boiler must be the same at commencement and end of trial, or else the difference must be allowed for. An engine trial should not be less than two hours, and should preferably be four or six hours; and readings of all the feed measuring instruments should be taken frequently—say, every 10 minutes or quarter of an hour. Frequently the feed water cannot be weighed directly, and then a weir, notch, or tumbling bay may be used; and although this device does not lead to direct measurement, it is one which we are compelled to adopt occasionally owing to the large quantities of water to be dealt with.

We have in this way obtained water supplied and heat added to convert it into steam. This, then, is work put into the engine, provided that all leakages from pipes, valves, etc., and steam consumed by pumps, etc., have been carefully measured and debited. The gross work performed by the engine is measured by the indicator diagram, and is called the indicated horse-power. This indicator should be fixed as closely as possible to cylinder, and be without bends or elbows.

In making engine trials of this description, the greatest care has to be taken to collect all drip cock, blow-off-cock, cylinder waste, etc. If practicable, the cylinder exhaust steam should be caught and weighed; this can easily be done with surface-condensing engines, and also with jet-condensing engines, but in the latter case condensing water must be measured in addition. In steam-jacketed engines a special record has to be kept of condensed steam from jackets also. In boiler testing, notes should be taken of temperature of furnace gases as they leave the boiler every 10 minutes, and also notes of damper opening. Gas and air samples should be collected two or three times during trial. Air samples give amount of moisture contained, tested by passing through calcium tube. Gas collecting should go on for half-hour at time through perforated collector in chimney. Measure volumes under known pressures and temperature, and test for CO_2 with calcic chloride. Decrease of volume of mixture when under same pressure tells how much absorption of CO_2 has taken place. A fresh sample, tested with pyrogallic acid, should give O present. Other boiler-house measurements should give coal used, ash collected, water levels, steam pressures, feed-valve openings, times, etc. Coal and ash samples should also be tested for calorific value and complete combustion, etc. Complete balance-sheet for trial should be drawn up, stating total heat received, how expended, and where losses have been made. Sheets of this character will be found in the Royal Agricultural Society's engine trial reports.

To illustrate another branch of applied science now usually taught in engineering schools, I give a few notes relating to the dynamics of a complicated mechanism. It matters not whether the particular machine be one used for electrical work or for any other purpose,

Digitized by Google

the principles involved in the one will be the same as those involved in the other, and the advantages gained in both cases will be equal. When any machine is put in motion, there are obviously stresses set up due to momentum and centrifugal force, etc., and it therefore becomes a matter of great importance to know precisely what these stresses amount to. These stresses may, of course, be calculated by pure mathematics, or the comparatively new science of the graphical calculus may be substituted to deal with the question. Another feature which this investigation shows is one which is of great importance to electrical engineers. It is of importance to get uniformity of motion of rotation. Such uniformity is impossible with the ordinary slider crank mechanism. The influence of both flywheel and governor is noticeable.

A highly interesting and attractive topic is the utilisation of the heat obtained from refuse destructors. It is almost impossible to say exactly what calorific value to attach to any given load of refuse, but it is tolerably easy to calculate from easily ascertained data the limit which it is impossible for it to exceed. There are three factors to be considered: (1) the combustible portion; (2) the incombustible; (3) the moisture. The calorific value of the combustible portion will certainly not exceed that of coal, consequently its limit is determined. The incombustible proportion may be ascertained by burning a given weight of the mixture in a neighbouring furnace, and the moisture may be ascertained by weighing the load before and after drying. These quantities can be ascertained at various periods of the year, and the amount of variation of each factor will give an idea of the fluctuation in calorific value at the different seasons. The heat generated by the combustion of a load of the mixture is utilised in three distinct ways: (1) in evaporating water in a boiler for useful purposes; (2) in evaporating its own moisture prior to its combustion; (3) in heating and fluxing the incombustible portion, the bulk of which heat is withdrawn from the furnace, when the clinkers are extracted. We will now take as an illustration a refuse containing 50 per cent. combustible, 25 per cent. clinker, and 25 per cent. moisture. (A very good sample.)

$\therefore$ 1lb. refuse contains $\frac{1}{4}$lb. water.
" " $\frac{1}{4}$lb. clinker.
" " $\frac{1}{2}$lb. combustible.

The heat theoretically required to evaporate $\frac{1}{4}$lb. water from 60deg. F. at 212deg. F. $= \frac{1,116}{4}$ B.T.U. $= 279$ B.T.U.

The heat lost in forming the clinker that is withdrawn will be about the same as that required for the melting iron in a cupola, or about $\frac{1}{4}$lb. coal to a $\frac{1}{4}$lb. clinker. If the calorific value of coal be taken at 14,500 B.T.U., then 1,825 B.T.U. are lost in clinker. The combustible portion will certainly be inferior to coal, and therefore will not contain more than 7,250 B.T.U. Hence the maximum net calorific value of 1lb. of refuse $= 7,250 - (1,825 + 279)$ B.T.U.

$= 5,146$ B.T.U.

Now, suppose this refuse could be burnt in a first-rate boiler, evaporating 10lb. water per 1lb. coal, then the gross evaporation would only amount to 3·5lb. per 1lb. This figure has been obtained (1) by selecting a refuse containing an exceptionally large proportion of combustible material; (2) by assuming the combustible portion equal to good coal, which it never is; (3) by assuming that the refuse can be burnt directly under a good boiler. We may therefore fairly assume that average refuse, as it is now collected in English towns, never can evaporate as much as 3·5lb. water from 60deg. at 212deg. F. per 1lb. refuse. If, on the other hand, a rather poorer refuse than the foregoing be considered, containing, say, 40 per cent. moisture and 30 per cent. incombustible, then under the same conditions and assumptions it may be found that 1lb. of refuse, at a maximum efficiency, can only evaporate 1·1lb. water. It is noteworthy that in the latter case the combustible portion of the refuse is bound to have a calorific value equivalent to 60 per cent. of that of good coal, otherwise the refuse would not burn without screening or the addition of more combustible fuel. This mode of calculation is, of course, only useful inasmuch as it leads us to a knowledge of the maximum evaporative power of a given refuse, beyond which it is absolutely impossible to get. These figures do not depend on the particular furnace in which the refuse is burned, and they, therefore, clearly demonstrate the absurdity of putting forward as fair average practice such high evaporative efficiencies as have been of late so freely circulated in the Press. They also show something more. Assume, for instance, that as much as 1lb. water can be evaporated per 1lb. refuse, and that a collection of 80 tons per diem be made. Then the water evaporated per hour is only $\frac{80 \times 2,240}{20}$lb. $= 7,466$lb., which may be taken as equivalent to about 300 b.h.p. per hour. A district containing 100,000 inhabitants might produce this refuse, and it has been said that this refuse would be sufficient to furnish light to the locality. Even the initial central station would probably be erected to supply a maximum of 400 units, or about 550 e.h.p., so that such a destructor by itself would be unable to account for much more than half the steam even at the inauguration of the installation. It is therefore clear that destructors, by themselves, can never do more than aid in the production of electric light. There are, however, very few purposes for which power is required continuously during the whole 24 hours, and this is, of course, especially true in the case of electric lighting. Thus it has been generally found that the lighting demand but rarely exceeds the average daily demand for more than eight hours except on very foggy days. Hence, if some means could be found for storing up the continuously generated energy of the destructor during the 16 hours' light load, we should then be in a position to supply three times the average power during the eight hours' heavy load.

(To be continued.)

BOARD OF TRADE REGULATIONS.

We give below the new regulations about to be issued by the Board of Trade. It will be noticed that suggestions are asked for, and we shall be glad to receive from our readers letters ventilating any new departure from the old code.

Botolph House, Eastcheap, London, E.C.
URGENT AND IMPORTANT. 30th May, 1895.

ELECTRICAL TRADE SECTION.

Revised Board of Trade Regulations under Electric Lighting Acts, 1882 and 1888.

Dear Sir,—You will doubtless have seen a copy of the revised "Regulations and Conditions for Ensuring a Proper and Sufficient Supply of Electrical Energy made by the Board of Trade under the Provisions of the Electric Lighting Acts 1882 and 1888." The above trade section of this Chamber have had these regulations under their consideration, and think it desirable that the views of central-station engineers and others interested should be obtained before representations are made to the Board of Trade on the subject. We shall, therefore, esteem it a favour if you will kindly give these regulations your consideration, and send the secretary of the Chamber at your earliest convenience any suggestions you may have to offer. A meeting of the section will be held on Tuesday, the 11th June, at 12 noon, to consider the regulations and any suggestions made, and to determine the nature of the representations to the Board of Trade.—Yours faithfully,

E. GARCKE, Chairman of Section.
KENRIC B. MURRAY, Secretary.

REGULATIONS AND CONDITIONS FOR SECURING THE SAFETY OF THE PUBLIC AND FOR ENSURING A PROPER AND SUFFICIENT SUPPLY OF ELECTRICAL ENERGY, MADE BY THE BOARD OF TRADE UNDER THE PROVISIONS OF THE ELECTRIC LIGHTING ACTS, 1882 AND 1888, AND OF THE —— ORDER.

Definitions.

In the following regulations:

The expression "the order" means the —— order.

The expression "the undertakers" means the undertakers for the purpose of the order.

The expression "consumer's wires" means any electric lines

Digitized by Google

on a consumer's premises which are connected with the service lines of the undertakers at the consumer's terminals.

The expression "aerial line" means any electric line which is placed above ground and in the open air.

The expression "pressure" means the difference of electrical potential between any two conductors through which a supply of energy is given, or between any part of either conductor and the earth, pressure on any alternating-current system being taken to be the equivalent of pressure on a continuous-current system when it produces an equal heating effect if applied to the ends of a thin stretched wire or carbon filament; and (*a*) where the conditions of the supply are such that the pressure cannot at any time exceed 300 volts if continuous, or the equivalent of 150 volts, if alternating, the supply shall be deemed a low-pressure supply; (*b*) where the conditions of the supply are such that the pressure may exceed the limits of a low-pressure supply, but cannot exceed 3,000 volts, or the equivalent of 3,000 volts, whether continuous or alternating, the supply shall be deemed a high-pressure supply; (*c*) where the conditions of the supply are such that the pressure may on either system exceed 3,000 volts, or the equivalent of 3,000 volts, the supply shall be deemed an extra high-pressure supply.

Mains, service lines, and other conductors and apparatus are referred to as low-pressure, high-pressure, and extra high-pressure mains, etc., according to the conditions of the supply delivered through the same or particular portions thereof.

Where these regulations require any metallic body to be "efficiently connected with earth," it shall be connected with the general mass of earth in such manner as will ensure at all times an immediate and safe discharge of electrical energy.

Other expressions to which meanings are assigned in the order or principal Act have the same respective meanings in these regulations.

A.—Regulations as to Safety.

I.—*General.*

(1) Save as hereinafter provided, the supply of energy delivered to the consumer's terminals shall be a low-pressure supply.

(2) A high-pressure supply shall not be delivered to any consumer's terminals, except for special purposes, and with the approval of the Board of Trade on the joint application of the consumer and the undertakers, and subject to such further regulations as the Board of Trade may from time to time prescribe. But a high-pressure supply may be given to distributing or converting stations or to transforming apparatus on a consumer's premises in accordance with the following regulations.

(3) An extra high-pressure supply shall not be given except to distributing stations or other premises in the sole occupation of the undertakers, and with the written consent of the Board of Trade, and subject to such regulations and conditions as the Board may prescribe.

(4) No high-pressure electric line shall be used for the transmission of more than 200,000 watts, or in the case of an aerial line 50,000 watts, except with the consent in writing of the Board of Trade, and efficient means shall be provided to prevent this limit being at any time exceeded.

(5) Every high-pressure electric line, conductor, or other apparatus shall be protected by a suitable automatic quick-acting cut-off.

(6) In every case where any transforming apparatus is used to convert a high-pressure supply into a low-pressure supply, some suitable automatic and quick-acting means shall be provided to protect the low-pressure system from any accidental contact with or leakage from the high-pressure system, either within or without the transforming apparatus.

(7) The maximum working current in any conductor shall not be sufficient to raise the temperature of the conductor or any part thereof to such an extent as to materially alter the physical condition or specific resistance of the insulating covering, if any, or in any case to raise such temperature to a greater extent than 30deg. F.; and efficient automatic means shall be provided which will render it impossible for this maximum working current to exceed such limit to the extent of 50 per cent., even for short intervals of time; and special care shall be taken that the cross-sectional area and conductivity at joints are sufficient to avoid local heating, and that the joints are protected against corrosion.

(8) The sectional area of the conductor in any electric line laid or erected in any street shall not be less than the area of a circle of 1-10in. diameter, and when the conductor is formed of a strand of wires each separate wire shall be at least as large as No. 20 standard wire gauge.

(9) Every electric line shall be tested for insulation after having been placed in position, the testing pressure being at least 200 volts, and the undertakers shall duly record the results of the tests of each line or section of a line. No electric line shall be brought into use in which this test indicates an insulation resistance less than at the rate of 100,000 ohms per mile for every volt of pressure of the supply, unless it is connected with earth with the consent of the Board of Trade, in which case the insulation resistance of such electric line shall not be less than 10 megohms.

(10) The insulation of every complete circuit used for the supply of energy, including all machinery, apparatus, and devices forming part of, or in connection with, such circuit, shall be so maintained that the leakage current shall not under any conditions exceed one-thousandth part of the maximum supply current; and suitable means shall be provided for the immediate indication and localisation of faults of insulation. Every such fault shall be remedied without delay. Every such circuit shall be tested for insulation at least once in every week, and the undertakers shall duly record the results of such testings. Provided that where the Board of Trade have approved of any part of any electric current being connected with earth, the provisions of this regulation shall not apply to such circuit so long as such connection exists.

(11) All material used for insulating electric lines or apparatus shall be of the best quality, and thoroughly durable and efficient, having regard to the conditions of its use. Suitable provision shall be made for the protection of the insulating material against injury or removal.

(12) Every high-pressure conductor shall be continuously covered with insulating material to a thickness of not less than one-tenth part of an inch, and in cases where the extreme difference of potential in the circuit exceeds 2,000 volts, the thickness of insulating material shall not be less in inches or parts of an inch than the number obtained by dividing the number expressing the volts by 20,000. If this protection be wholly or partly metallic, it shall be efficiently connected with earth.

(13) No electric line, machine, device, or apparatus intended to form part of, or be connected with, a high-pressure circuit shall be brought into use unless the insulation thereof has withstood the continuous application during one hour of twice the pressure to which it is intended to be subjected in use. The undertakers shall duly record the results of such test.

(14) Where any portion of any electric line or any support for an electric line is exposed in such a position as to be liable to injury from lightning, it shall be efficiently protected against such injury.

(15) Where any accident by fire or explosion, or any accident causing or likely to have caused personal injury occurs at any part of any electric line or work to which these regulations apply, the undertakers shall give immediate notice thereof to the Board of Trade.

II.—*Aerial Lines where Erected with the Necessary Consents.*

(16) Every aerial line shall be attached to supports at intervals not exceeding 200ft. where the direction of the line is straight, or 150ft. where this direction is curved, or where the line makes a horizontal angle at the point of support.

(17) Every support of aerial lines shall be of a durable material, and properly stayed against forces due to wind pressure, change of direction of the lines, or unequal lengths of span. The factor of safety for the lines and suspending wires shall be at least 6 and for all other parts of the structure at least 12, taking the maximum possible wind pressure at 50lb. per square foot. No addition need be made for a possible accumulation of snow. Every support if of metal shall be efficiently connected with earth.

(18) Aerial lines shall be attached to insulators, and shall be so guarded that they cannot fall away from the support. Conductors covered with insulating material shall not be attached to the insulators by metal binders.

(19) An aerial line shall not in any part thereof be at a less height from the ground than 18ft., or where it crosses a street 30ft. [*Note.*—In the county of London 35ft.], or within 5ft. measured horizontally, or 7ft. measured vertically, from any building or erection other than a support for the line, except where brought into a building for the purpose of supply.

(20) Service lines from aerial lines shall be led as directly as possible to insulators firmly attached to some portion of the consumer's premises which is not accessible to any person without the use of a ladder or other special appliance, and from this point of attachment they shall be enclosed and protected in accordance with the regulations hereinafter contained as to service lines on the consumer's premises. Every portion of any service line which is outside a building but is within 7ft. from such building shall be completely enclosed in stout india-rubber tubing.

(21) Where an aerial line crosses a street, the angle between such line and the direction of the street at the place of such crossing shall not be less than 60deg., and the spans shall be as short as possible.

(22) Where an aerial line crosses, or is in proximity to, any metallic substance, precautions shall be taken by the undertakers against the possibility of their line coming into contact with such metallic substance, or of such metallic substance coming into contact with their line by breakage or otherwise.

(23) Every high-pressure aerial line shall be efficiently suspended by means of insulating ligaments to supending wires, so that the weight of the line does not produce any sensible

Digitized by Google

stress in the direction of its length. All suspending wires, if of iron or steel, shall be galvanised.

(24) In the case of any aerial line exceeding one-half mile in total length, means shall be provided whereby the pressure may be discharged from any portion of such line erected over or alongside of any building or buildings without loss of time in case of fire or other emergency.

(25) Every aerial line, including its supports and all the structural parts and electrical appliances and devices belonging to or connected with such line, shall be duly and efficiently supervised and maintained as regards both electrical and mechanical conditions.

(26) An aerial line shall not be permitted to remain erected after it has ceased to be used for the supply of energy, unless the undertakers intend within a reasonable time again to take it into use.

III.—*Electric Lines other than Aerial Lines.*

(27) All conduits, pipes, or casings used as receptacles for electric lines shall be constructed of durable material, and of ample strength to prevent damage from heavy traffic, and where they are laid in streets in which gas-mains are also laid shall be so constructed as to prevent any influx of gas from the adjacent soil.

(28) Where any electric line crosses, or is in proximity to, any metallic substance, special precautions shall be taken by the undertakers against the possibility of any electrical discharge to the metallic substance from their line or from any metal conduit pipe or casing enclosing their line.

(29) All metal conduits, pipes, or casings containing any electric line shall be efficiently connected with earth, and shall be so jointed and connected across all street boxes and other openings as to make good electrical connection throughout their whole length.

(30) Where isolated lengths of metal conduit, pipe, or casing are used for the protection of any electric line at road crossings or similar positions, there shall be interposed between such electric line and the conduit, pipe, or casing such additional insulating material as will prevent the possibility of any electrical charging thereof.

(31) Where the conductors of electric lines placed in any conduit are not continuously covered with insulating material they shall be securely fixed in position, and no unfixed material of a conducting nature shall be contained in the conduit. Adequate precautions shall also be taken to ensure that no accumulation of water shall take place in any part of the conduit, and to prevent any access of moisture to the conductors or the insulators, and the latter shall be so disposed that they can be readily inspected.

(32) Any portions of any high-pressure electric lines placed above the surface of the ground or in any subway shall be completely enclosed either in a highly-glazed porcelain tube embedded in brickwork, masonry, or cement concrete, or in strong metal casing efficiently connected with earth, and so protected and guarded as to prevent accidental contact with the casing.

(33) Every high-pressure electric line transmitting more than 50,000 watts, or used for the supply of energy to transformers placed in street boxes, shall, except within the generating station, be entirely enclosed in strong metal casing efficiently connected with earth, and such casing shall not contain any low-pressure electric line.

(34) High-pressure electric lines not intended to transmit more than 50,000 watts may be enclosed either as provided in the preceding regulation, or in glazed stoneware casings properly laid and jointed in cement at a depth of not less than 2ft. below the surface of the ground and sufficiently protected against breakage.

IV.—*Street Boxes.*

(35) All street boxes which contain any vacant space shall be so constructed as to prevent any influx of gas or water either from the adjacent soil or by means of any pipes, and ample provision shall be made by ventilation or otherwise for the immediate escape of any gas which may by accident have obtained access to the box and for the prevention of danger from sparking.

(36) The covers of street boxes shall be properly secured, and shall, where the box contains high-pressure apparatus, be connected to strips of metal laid immediately underneath the adjacent roadway or pavement.

(37) The casing of any high-pressure electric lines shall be continued within street boxes.

V.—*Converting Stations.*

(38) All converting stations, or points in a system of distribution to which a high-pressure supply is given from generating stations, and from which a low-pressure supply is given to consumers, shall be established in suitable places which are in the sole occupation and charge of the undertakers.

VI.—*Consumer's Premises.*

(39) The undertakers shall be responsible for all electric lines, fittings, and apparatus belonging to them, or under their control, which may be upon the consumer's premises being maintained in a safe condition and in all respects fit for supplying energy.

(40) In delivering the energy to the consumer's terminals the undertakers shall exercise all due precautions so as to avoid risk of causing fire on the premises.

(41) A suitable safety fuse or other automatic disconnector shall be inserted in each service line as close as possible to the point of entry to any consumer's premises, and contained within a suitable locked receptacle of fireproof construction.

(42) All low-pressure electric lines and apparatus placed on any consumer's premises shall be highly insulated and thoroughly protected against injury to the insulation or access of moisture, and no metal forming part of the electric circuit shall be exposed so that it can be touched. All electric lines shall be so fixed and protected as to prevent the possibility of electrical discharge to any adjacent metallic substance.

(43) Where transformers are installed within buildings on consumers' premises, they shall be contained in a fireproof chamber securely locked, and the high-pressure service lines in highly-glazed porcelain tubes bedded in chases cut in brickwork or masonry.

(44) If the undertakers are reasonably satisfied, after making all proper examination by testing or otherwise, that a connection with the earth exists at some part of a circuit of such resistance as to be a source of danger, and that such connection does not exist at any part of the circuit belonging to the undertakers, then and in such case any officer of the undertakers, duly authorised by them in writing, or, if the undertakers so require, an electric inspector may, for the purpose of discovering whether such connection with the earth exists at any part of a circuit within or upon any consumer's premises, at all reasonable times, after giving one hour's notice of his intention to do so, enter any such premises and disconnect the consumer's wires from the service lines, and may require the consumer to permit him to inspect and test the wires and fittings belonging to the consumer and forming part of the circuit. In any case where the undertakers require the services of an electric inspector under this regulation they shall pay him the prescribed fee.

(45) If on such testing, the officer or the electric inspector discovers that a connection exists between the consumer's wires and the earth, and that such connection has an electrical resistance not exceeding 5,000 ohms, or if the consumer does not give all due facilities for such inspection and testing, the undertakers shall forthwith discontinue the supply of energy to the premises in question, giving immediate notice of such discontinuance to the consumer, and shall not recommence such supply until they are reasonably satisfied that such connection with the earth has been removed. Provided that in cases where the maximum power taken by any consumer exceeds 25,000 watts, the consumer's wires may be divided for the purpose of this testing into separate circuits, the insulation resistance of each of which shall exceed 5,000 ohms.

(46) If any consumer is dissatisfied with the action of the undertakers either in discontinuing or in not recommencing the supply of energy to his premises, the wires and fittings of such consumer may, on his application, and on payment of the prescribed fee, be tested for the existence of connection with the earth by an electric inspector. This regulation shall be endorsed on every notice given under the provisions of the last preceding regulation.

VII.—*Arc Lighting.*

(47) All arc lamps shall be so guarded as to prevent pieces of ignited carbon or broken glass falling from them, and shall not be used in situations where there is any danger of the presence of explosive dust or gas.

(48) Arc lamps used in any street shall be so fixed as not to be in any part at a less height than 10ft. from the ground.

(49) A cut-off switch, fixed in a suitable locked receptacle, shall be provided for every high-pressure arc lamp, and such switch shall be of such pattern and construction as will provide (*a*) that the lamp can by its means be entirely disconnected from the supply circuit; (*b*) that the switch itself can be safely operated in the dark by an inexperienced person and without special precautions; and (*c*) that there shall be no danger of any injurious electrical arcing, sparking, or heating being caused by the operation of the switch.

Penalties.—(50) If the undertakers make default in complying with any of the preceding regulations, they shall be liable to a penalty not exceeding £10 for every such default, and to a daily penalty not exceeding £10. The imposition of any penalty under this regulation shall not affect the liability of the undertakers to make compensation in respect of any damage or injury which may be caused by reason of such default.

B.—Regulations as to Supply.

(1) One week at least before the undertakers are ready to commence to supply energy through any feeding, charging, or distributing main they shall serve a notice upon the local authority of their intention to commence such supply.

(2) From and after the time when the undertakers commence to supply energy through any distributing main they shall

Digitized by Google

maintain a supply of sufficient power for the use of all the consumers for the time being entitled to be supplied from such main; and such supply shall, except so far as may be otherwise agreed upon from time to time between the local authority and the undertakers, be constantly maintained. Provided that, for the purposes of testing, the authority by whom the electric inspector is appointed may give permission to the undertakers to discontinue the supply at such intervals of time and for such periods as it may think expedient, and that for any other purposes connected with the efficient working of the undertaking, the undertakers may, with the permission of the Board of Trade, discontinue the supply at such intervals of time and for such periods as the Board of Trade may think expedient. Where the supply is so discontinued, notice of such discontinuance, and of the probable duration thereof, shall be forthwith served upon the local authority.

(3) The system of distributing mains shall be so arranged that in case it becomes necessary to stop the supply through any portion of a main for more than one hour, for the purposes of repairs, or for any other reason, the stoppage of supply will in no case exceed in amount a maximum power of 200,000 watts, or extend to the premises of more than 80 consumers, and in the case of every stoppage for more than one hour reasonable notice shall be previously given by the undertakers to every consumer affected thereby except in cases of emergency.

(4) During the whole of the period when a supply of energy is required to be maintained by the undertakers in the distributing mains under the order and these regulations, it shall be maintained at a constant pressure (in these regulations termed the "standard pressure") to be fixed as hereinafter specified; but such standard pressure may be different for different portions of the distributing mains. Provided that the undertakers shall be deemed to have complied with the requirements of this regulation so long as the pressure does not at any point vary more than 3 per cent. from the corresponding standard pressure in the case of a general supply at low pressure, or 2 per cent. in the case of a general supply at high pressure, unless changes in pressure recur so frequently as to cause unsteadiness in the supply.

(5) The standard pressure shall be fixed by the undertakers for every pair of distributing mains, and notice of the amount of such standard pressure shall be given to the local authority before the undertakers commence to supply energy to consumers through such mains, and such standard pressure shall not be altered except by permission of the local authority, and upon such terms and conditions as the local authority may impose, and after public notice has been given during a period of one month, in such manner as the local authority may require, of the intention of the undertakers to apply for permission to alter the same. The undertakers may appeal against any decision of the local authority under this regulation to the Board of Trade, whose decision shall be final.

(6) Before commencing to give a supply of energy to any consumer, the undertakers shall declare to such consumer the constant pressure at which they propose to supply energy at his terminals. The pressure so declared at any pair of consumer's terminals shall not, except by agreement, be greater than 150 volts or less than 45 volts if continuous, or the equivalents thereof respectively if alternating, and shall not at any time be altered or departed from except in consequence of any authorised alteration of the corresponding standard pressure. In distribution on the three-wire system, the central terminal shall for the purposes of this regulation be considered to form a pair with either of the outer terminals, and similarly for multiple-wire systems; and, in the case of a transformation of energy on the consumer's premises, the undertakers shall give the consumer the choice of a supply at either of two different pressures, one of which shall be approximately half the other, and in such case the pressure so chosen by the consumer shall be the declared constant pressure.

(7) The variation of pressure at any consumer's terminals shall not under any conditions of the supply which the consumer is entitled to receive, nor at any time, exceed 4 per cent. from the declared constant pressure, whether such variation be due to the resistance of the service lines or apparatus belonging to the undertakers, or to any action or effect produced by such apparatus, for which the consumer cannot be shown to be responsible, or, partly to any variation of pressure in the distributing mains from which the supply is taken.

(8) If the undertakers make default in complying with any of these regulations as to supply, they shall, subject to the provisions of the order, be liable to a penalty not exceeding £5 for every such default, and to a daily penalty not exceeding £5.

These regulations are made subject to the power of the Board of Trade to make such further or other regulations as they may think expedient, and nothing in these regulations shall be construed to authorise the undertakers to lay any electric line or work their undertaking otherwise than in accordance with the order and the principal Act, or to supply energy otherwise than by a system for the time being approved of by the Board of Trade under the order.

THE CITY AND WATERLOO RAILWAY.

On Tuesday evening a large party of members of the Institution of Junior Engineers paid a visit of inspection to the Waterloo and City railway works. A practical beginning of this undertaking was made about this time last year, and the company were able to traverse about half-a-mile of completed tunnelling. There are virtually two railways now lying down beneath the bed of the Thames near Blackfriars Bridge, each line being a quarter of a mile long at present. One, of course, is the "up" line, the other the "down." The two tunnels are not of the same size, and they do not take precisely the same course. The one of them running from Waterloo to the City is 12ft. 1½in. in diameter, the one in the opposite direction 12ft. 9in. The reason of this is that, as it has been said, the two lines take slightly different courses, and one has rather sharper curves than the other, and the carriages will require somewhat more space to curve round in. It would have been possible, of course, to make the tunnel slightly larger at the turning points, but it was deemed best upon the whole to make the enlargement throughout. The reason that the two lines do not run side by side all the way is that it is desirable to have a sharp gradient at the starting point and an easy one at the terminus of each line so that the levels of the two lines vary considerably, the difference of incline ranging from 1 in 800 to 1 in 60.

These and other details were explained to the visitors, says the *Daily News*, by Mr. Campbell, one of the assistants of the contractors, Messrs. Mowlem and Co., and the drawings were exhibited. The large company then proceeded in sections to descend to the works they had had described, the descent of about 70ft. being made by means of ladders fixed almost perpendicularly between three or four stages. When the works are going, the electric light is used throughout, operations being carried on during the whole 24 hours. Owing to the Whitsuntide holidays, however, the tunnels were in darkness when the first companies descended, and a singular-looking procession, with lamps and candles, burrowed its way along the gloomy galleries to the heading at the southern end, where an air-lock has been constructed, and preparations made for carrying on the work under air pressure, in anticipation of the tunnels emerging from the clay through which the whole of the river passage has been made, and penetrating a watery gravel. The visitors were warned beforehand that those of them who were conscious of any little weakness of heart, or who were suffering from a cold, had better not enter the air-lock, though the pressure at present was supposed to be only about 12lb. to the square inch above the normal. On reaching the lock, however, it was found that such little pressure as there had been had leaked away, and the company were able to inspect the arrangements without undergoing the pneumatic ordeal.

Thus far this undertaking has been carried on without any necessity for pneumatic pressure, the borings having been made through the sunken clay with 20ft. of it or so between the top of the tunnels and the bed of the river. Air-locks are, however, now about to be brought into operation at the headings on both sides of the river. At the southern extremity of the up-line tunnel the party, with their lamps and candles, halted for a time to get details of the working of the shield and the construction of the tunnel. The Greathead system of subterranean boring is now pretty generally understood in its main features. A circular shield with a cutting edge is driven by sheer hydraulic pushing through the soil, whatever it may be. But in front of this shield a "heading" is carried forward some feet in advance, this heading being excavated in the usual way by pickaxe and shovel. The centre of the tunnel being thus formed, the shield is driven forward and the full size of tunnel is cleanly sliced out. In this work the hydraulic force is applied by seven rams fixed at the back of the shield all round and operated on by hand pumps, the power applied being about 800lb. on the square inch. The cutting shield having been driven forward, the circular iron lining of the tunnel is fixed round in segments and belted together. In order to give a backing to this ironwork, and to fill up any irregularities of the surface of the soil behind it, grouting is poured in through small holes here and there. This soon sets as hard as solid rock. About 10ft. of tunnel can ordinarily be thus completed in the 24 hours. With this massive iron lining embedded in the grouting behind, the tunnel might be regarded as complete. In this case, however, the interior is concreted all round to the level of the ironwork flanges, this being done chiefly as a means of reducing the noise that has been found very unpleasant where the iron has been left uncovered.

The whole line when completed will be about a mile and a half in length. One terminus will be immediately beneath the South-Western Station at Waterloo. The other will be near the Mansion House, and will eventually have subterranean connection with the projected Central London Electric Railway, for which parliamentary powers have been obtained, and of

Digitized by Google

which the public will probably hear more before very long. There will be no intermediate station between the City and Waterloo, though it seemed doubtful at one time whether one could not be constructed at Blackfriars. The trains will run from end to end without stopping, and as from each end they will start down a steep incline the journey will be performed in both directions very largely by the momentum thus acquired, supplemented, however, by electricity. The construction of the line is being carried on from a central point in the river marked by the conspicuous pile of staging within a short distance of Blackfriars Bridge, both tunnels being driven simultaneously in each direction. On one side of the river the course will be from a point in the river bank, a little to the east of Bull Stairs Alley, to the junction of Hatfield and Stamford streets, along Stamford-street to the corner of York-road and Waterloo-road, and thence to the terminus. In the other direction it will emerge from the river at the north-west corner of Blackfriars Bridge, and will pass up beneath the middle of Queen Victoria-street, having above it at one point a main sewer, and the District Railway above that. The terminus at the City end will be 63ft. below the roadway, while at the other the station will be 35ft. below the South-Western platforms. Waterloo being built upon arches renders it comparatively easy to bring in this new line beneath it. The estimated cost of the new line is half a million of money, and it should be completed in about 18 months from the present time. The work thus far appears to have gone on very smoothly and rapidly, and though the most troublesome part of the business is probably about to be entered on, there is no reason to apprehend any great difficulty in rapidly and successfully carrying it through. Great interest was evinced in all the engineering details of the work, and votes of thanks were accorded to Messrs. Mowlem for permitting the inspection, and to Mr. Campbell for generously sacrificing a portion of his brief holiday to the task of conducting this large party over the works.

LEGAL INTELLIGENCE.

MARSHALL v. SOUTH STAFFORDSHIRE AND BIRMINGHAM TRAMWAY COMPANY.

In the Appeal Court on Thursday last week, before the Master of the Rolls and Lords Justices Smith and Rigby, the appeal of the defendants in the case Marshall *v.* South Staffordshire and Birmingham Tramway Company was heard.

The plaintiff, Mr. Gerald Cook Rodgers Marshall (Chelmsford), brought an action to recover £400 principal and £50 interest upon his mortgage debentures in the defendant company, which is registered at Darlaston. Baron Pollock allowed the plaintiff to sign final judgment under order 14, and the defendants appealed for leave to defend on the ground that they had an absolute defence to the action both as regarded the principal and as regarded the interest.

Mr. Murphy, Q.C., who appeared in support of the company's appeal, said that the defence was that the principal was not due until August, 1893, and the interest still later. Mr. Willis Bund appeared for the respondent.

The **Master of the Rolls** said it was not a case for order 14, and the plaintiff was not entitled to sign the final judgment. The order of Baron Pollock was not a peremptory one, and the appeal would be allowed, with costs in that Court and in the Court below.

The other Lords Justices concurred.

The case will now come on for trial in the ordinary way.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Braila.—Tenders are invited by the municipal authorities of Braila, Roumania, by June 17 (29), for lighting the town by gas and electricity. Security required, 25,000f.

Grimsby.—Tenders are invited for the lighting of the public streets for one year, for the Urban Sanitary Authority. We have already given particulars. Tenders are to be delivered by 5 p.m. to-day (Friday.)

Edinburgh.—The Town Council invite tenders for painting the street electric lamp-posts. Specifications are obtainable from the resident electrical engineer, 5, Dewar-place, Edinburgh. Tenders are to be sent in by 10th inst.

Paris.—Tenders are invited for electric lighting plant for the Boucicaut Hospital by the Bureau des Travaux de l'Assistance Publique, 3, Avenue Victoria, Paris, the estimated cost being 68,000f., or, say, £2,720, and for electric light fittings, the estimated cost being 40,000f., or, say, £1,600.

St. Pancras.—Tenders are invited for the supply of Welsh steam coal, suitable for electric works (colliery and seam to be stated), for 12 months from July 1, 1895, delivery to be made as required, average about 60 tons per week, for the Vestry of St. Pancras. Tenders to be sent to Mr. Albert E. Pycraft, chief clerk, electricity and public lighting department, Vestry Hall, Pancras-road, endorsed "Tender for Coal," by 12 noon on 13th inst.

London, E.C.—Tenders are invited by the G.P.O. for the purchase of about 35 tons of old copper (wire, plates, etc.), a large quantity of other metals (brass, zinc, iron, and steel), india-rubber-covered wire, mercury deposit, indiarubber, tinfoil, felt, rope, tar barrels, raw hide pieces, etc. A form of tender can be obtained from Mr. Charles E Stuart, controller of stores, G P.O., Telegraph-street, E C. Tenders will be received until Monday, June 17.

Madrid.—The Spanish Postal and Telegraphic Administration invites tenders by June 28 for the supply of 20 tons of copper. Preliminary security 5 per cent., definitive security 10 per cent., maximum price 520 pesetas per ton. Conditions, etc., and forms of tender from La Direccion General de Correos y Telégrafos, Madrid.—Tenders are invited up to June 10, 1895, by La Direccion General de Obras Publicas, Madrid, for the construction and working of a tramway from Murcia to Alcantarilla and Espinardo. Security, 3,498 pesetas.

York.—Tenders are invited for the following articles during six months ending December 31, 1895 delivered carriage paid at the stores at York, for the North-Eastern Railway Company: (1) telegraph apparatus; (2) telegraph wire and line stores. Payment for each month's delivery will be made at the end of three clear months, or in cash, less 2½ per cent discount. Forms of tender may be obtained on application to Mr. Graves, Telegraph Department, York, and tenders must be sent to Mr. C. N. Wilkinson, secretary, York, sealed, and marked "Tender for Telegraph Stores," by noon on June 10.

London.—The Secretary of State for War gives notice that purchases for specific quantities of various articles will be made from time to time during the current year. Among them are electrical instruments for submarine mining and telegraph cable and wire. Manufacturers who may be desirous of tendering should apply to Mr. G. Lawson, director of army contracts, War Office, Pall-mall, S W., by letter, giving at least names of two well-known firms or public bodies who have purchased from them and are in a position to certify as to the quality of their productions. Applications unaccompanied by references will not be noticed. Firms whose names are already on the War Office list need not apply, as forms for tendering will be sent to them in due course.

St. Helens.—The Electric Lighting Committee of the Corporation are prepared to receive tenders for the supply and erection of the following plant: Section A—boiler-house plant, including boilers and fittings, forced draught apparatus, feed pumps, etc.; Section B—engine-house plant, including steam alternators, oil-filter, fittings, etc., steam, exhaust, feed, blow-off, and sundry pipes, valves, and water-tanks, etc.; Section C—main switch-board and instruments; Section D—underground work, including cables, junction-boxes, culverts, and trenching; Section E—transformers and fittings; Section F—meters; Section G—overhead crane. Tenderers are at liberty to tender for any section or sections, or for the whole of the sections, but not for part of a section. The ground plan of plant, plan of streets, etc., and specification, with terms and conditions of tender and contract, may be obtained at the offices of Mr. Robert Hammond, the consulting engineer to the Corporation, Ormond House, Great Trinity-lane, London, E.C., on and after June 11, on payment of £2 2s., which sum will be returned on receipt of a bona fide tender. Tenders, sealed, and marked "Tender for Electric Lighting," must be addressed to the town clerk at the Town Hall, St. Helens, and be delivered on or before Tuesday, July 2.

RESULTS OF TENDERS.

Chester. - The City Council have accepted the tender of Messrs. Parker and Co., Wolverhampton, for carrying out an installation of the electric light as the illuminant for the public streets.

Cheltenham.—The Corporation have received the following tenders for the wiring of the library for electric light: Messrs. R. E. and C. Marshall, £105. 10s. 6d. (accepted); Mr. A. G. Sanders, £118. 9s.

Burton-on-Trent.—The Town Council have accepted tenders for the supply of coal from the Sheffield Coal Company, the Staveley Coal and Iron Company, and Messrs. J. and G. Wells for the electric light station, and the tender of the Telegraph Manufacturing Company, of Helsby, near Warrington, for the supply of high and low pressure cables for the extension of the electric light into the outlying parts of the town. The tender of the Stanton Ironworks Company for cast-iron pipes has also been accepted.

Change of Partnership.—Notice is given that the partnership lately subsisting between James Aram Lea, Francis James Lea, and Arthur Henry Lea, carrying on business as electrical and general engineers and art and general metal workers at Pengwerne Works, Chester-street and The Square, Shrewsbury, under the style of Lea, Sons, and Co., has been dissolved by mutual consent, so far as regards Arthur Henry Lea, the junior partner of the said firm, who retires therefrom. All debts due to or owing by the said late firm will be received and paid by James Aram Lea and Francis James Lea, the senior partners thereof, who will continue the business under the style of Lea, Son, and Co.

Digitized by Google

BUSINESS NOTES.

Western and Brazilian Telegraph Company.—For the past week the receipts were £2,659.

Bridlington.—It is stated that the Urban District Council have made the last payment towards the electric light plant.

Siemens and Halske.—It is reported that the Vienna firm of Siemens and Halske is about to be converted into a joint-stock company.

Direct Spanish Telegraph Company.—For the month of May the receipts were £2,017, as against £1,594 for the same period of 1894.

Eastern Telegraph Company.—The receipts for the month of May were £68,382, as against £54,846 for the corresponding period of 1894.

Hobart Electric Tramway Company, Limited.—The annual general meeting will be held on 11th inst. at the London offices, College-hill, E.C.

Nottingham.—Additions are being made to the Nottingham Station of the Midland Railway Company, and an electric lighting plant is to be laid down.

Eastern Extension Telegraph Company.—For the month of May the receipts show an increase of £660 as compared with the corresponding period of 1894.

Aberdeen.—The Town Council have received a communication from the Board of Trade as to proposed amendment of regulations, and this has been remitted to the Gas Committee.

Bell's Asbestos Company, Limited.—The directors of this Company have elected as a member of the Board Mr. W. Claude Johnson, M.I.C.E., of the firm of Messrs. Johnson and Phillips.

New Departure in Arc Lighting.—Messrs. Drake and Gorham inform us that they will in a few weeks' time put on the market the Jandus arc lamp, which will burn for 200 hours with one pair of carbons.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 26th ult. amounted to £1,146, as compared with £830 in the corresponding week of last year, being an increase of £316.

Portsmouth.—Arrangements for the installation of the electric light at St. Agatha's Church, Landport, have been entered into by the Town Council. The current will be supplied to both the old and new church buildings.

West Cowes.—Mr. Nelson Dennis, the surveyor to the West Cowes Urban District Council, has drawn up a scheme for the electric lighting of the town. Mr. Francis H. Medhurst has been called in to report on the same.

Kendal.—The Town Clerk informed the Town Council that the Board of Trade had communicated to the parliamentary agents that the Windermere Electricity Company had withdrawn the application to include Kendal in the provisional order.

Dublin.—On Friday last a meeting of the members of the Dublin Mercantile Association, who are subscribers to the telephone exchange, was held for the purpose of drawing attention to various grievances connected with the present telephone system.

Ayr.—The Town Council have resolved to introduce the electric light into the Municipal Buildings, and to get the Police Commissioners and one of the Corporation's tenants to pay 5 per cent. on the internal fittings, in addition to holding them liable for the upkeep of the internal fittings.

Agency.—Messrs. Francis and Spilsbury, electrical agents and suppliers, of Mansion House-chambers, 20, Bucklersbury, London, E.C., have taken up an agency for Messrs. A. P. Lundberg, Bradbury Electrical Works, Kingsland, and are now in a position to supply their manufactures from stock.

Val D'Aosta Electric Power Company, Limited.—This Company has been registered, with a capital of £80,000, to acquire, take up, and hold concessions for the utilisation of water, etc., in any part of the world, and to carry on the business of an electric light and power company in all its branches.

City and South London Railway.—The returns for the week ended June 2 were £929, compared with £869 for the corresponding period of 1894, being an increase of £60. The total receipts for the current period of the present half-year are £20,533 against £20,013 in the corresponding period of 1894, an increase of £520.

Large Hungarian Electrical Company.—Some stir has been created in Austrian and German electrical circles by the announcement that the Hungarian Kreditbank, in conjunction with the firm of Ludwig Loewe and Co., purposes founding a new general electric and finance company in Budapest, with a capital of 5,000,000fl., or £500,000.

Fulham.—The Vestry have instructed the clerk to invite not more than three electrical engineers of good standing, to be named by the committee, to state their fees for a complete report on, and full estimate of expenditure for, the installation and maintenance of the electric light for the parish of Fulham in conjunction with a dust destructor.

Coventry.—A meeting of the Town Council has been held, at which Mr. West moved the adoption of a report from the Electric Lighting Committee embodying detailed instructions for the management of the electric light undertaking on a commercial basis, which was adopted with the addition of a clause providing for a financial return to be submitted annually.

Ootacamund (India).—The Oriental Electric Light Company, of London and Bombay, having decided to establish a branch business in Ootacamund, the company's agent, Mr. A. B. Simpson, has arrived there and is prepared to furnish estimates for lighting the principal residences, clubs, hotels, etc., on the maintenance electric supply system by storage on the hire system.

Rickmansworth.—A meeting of the Parish Council has been held, at which Mr. Dockree said he found from an electrician that they had enough water power at Batchwood Bridge to supply Rickmansworth with electric light at £500 less than it cost to supply the town with gas. At the present time gas cost £2,000 a year, and they could furnish the town with electric light for £1,500.

Kensington.—The Fire Brigade Committee of the Kensington Board of Guardians has recommended that no action be taken upon the London County Council's letter on the subject of telephonic communication with the nearest fire station, it being pointed out that the expense would be hardly justified, seeing that the present alarm post was so close to the house. The committee's report was adopted by the Board.

Protection from Fire.—We are informed that the Chelsea Electricity Supply Company have just had a number of Merryweather's improved hydrants and hose, etc., fitted up at their Draycott-place station, and that this firm has carried out similar work for the Brush Electric Light Company, the Metropolitan Electric Supply Corporation, the Edison and Swan, and several other important companies.

Large German Undertaking.—A short time ago several prominent banking firms, in conjunction with the Elektricitäts-Gesellschaft vormals Schuckert and Co., founded a joint-stock concern entitled the Kontinentale Gesellschaft für Elektrische Unternehmungen (Continental Company for Electrical Enterprises) with a capital of 16,000,000 marks, or £800,000. It is stated that 7,000,000 marks, or £350,000, of this amount has already been paid up.

Tonbridge.—Mount Pleasant Congregational Church has been reopened after alterations and repairs. This is the first church in the town in which electric light fittings are to be seen. The fittings for the electric light have been installed by Messrs. Verity and Sons. The pulpit is furnished with two combination standards for both gas and electricity, and these are so arranged that at any moment the minister can turn on the gas or electricity, or both, at the same time.

Electric Lighting of the Houses of Parliament.—In the discussion on supply in the House of Commons the other evening, Mr Weir expressed the opinion that the electric light ought to be universally adopted in the Houses of Parliament, but Mr. A. C. Morton thought it would be unwise to spend too much upon additional electric light. Mr. Herbert Gladstone, in reply, said he thought on the whole that the House should be provided with current by an independent company.

Appointment Vacant.—There is required, as assistant gas and electricity manager, by a gas company in West Australia, a young married man, who is thoroughly and practically acquainted with gas manufacture and gasworks construction and management; also capable of taking charge of electric lighting plant. Wages £250 per annum, with house, light, and fuel. State age, family, general qualifications, etc, and give references or copies of recent testimonials, to Box 61, P. O., Oldham.

Belfast.—A meeting of the Electric Light Committee of the Corporation has been held, when the engineer (Mr. M'Cowen) submitted applications from the Belfast and Northern Counties Railway Company and the Ulster Hall Company for the supply of current, both of which would necessitate the extension of the present system of mains, and he was instructed to enquire as to the probable consumption and the prospects for further demands for lighting in those districts, and report at next meeting.

Wandsworth.—A meeting of the District Board has been held, at which permission was granted the County of London and Brush Provincial Electric Lighting Company to lay their mains in the Board's district; but the Board disapproved of the construction of the proposed converting stations or transformer-chambers, and the electric lighting company are to be informed that the Board are of opinion that the required stations or chambers should be constructed on land not forming part of the public way.

Hammersmith.—The Electric Lighting Committee of the Vestry having viewed installations at Chelsea, Ealing, St. Pancras, and Portsmouth, have advised the Vestry that they could not recommend them to adopt the report of Messrs. Williams and King. The Vestry have, however, decided to advertise for complete schemes and tenders for boilers, machinery, mains, etc., necessary to carry out the work included in the compulsory area. When these are received the Vestry will proceed to consult one or more engineers to advise on the subject.

Chelmsford.—The Lighting Committee of the Town Council at the last meeting of that body recommended that the Board of Trade electric lighting order be transferred from Crompton and Co., Limited, to the Chelmsford Electric Lighting Company, Limited. Alderman Duffield asked a question as to the security, whereupon Councillor Britton, the chairman of the Lighting Committee, rose to say he thought this matter might be allowed to go through without further discussion. It had been on for two years, and ought now to drop. The recommendation of the committee was adopted after some discussion.

Douglas (Isle of Man).—The Douglas Town Commissioners, at a specially convened meeting on Friday afternoon, had under con-

Digitized by Google

sideration an important offer from the Douglas Bay Tramway Company. The company agreed, in return for the concession of being permitted to lay a double line along the front of Douglas Bay, and of an extension of the present lease, which terminates in three years, for 21 years, to pay the Commissioners £1,500 a year and construct and work a tramway to Upper Douglas. The latter undertaking is calculated to result in a loss to the company of £1,000 a year for some years to come, but it is expected that the extension of the lease of the Douglas Bay tramway will more than make up for the loss. The debate was adjourned.

Dover.—A meeting of the Town Council has been held, at which the report of the proposed Board of Trade regulations in reference to the electric light which had been referred to Mr. Slingo for consideration was received Mr. Slingo stated that they were generally satisfactory, but it was desirable that the ventilation, etc , of street boxes should be more efficient to prevent accumulation of gas. He also suggested that an independent and careful examination of the mains and works should be made. Councillor Ayers, seconded by Councillor Clark, moved that no action should be taken, but on the motion of Alderman Adcock, seconded by Alderman Pepper, it was decided to refer the matter to the Electric Light Committee to report on, and if it were necessary to appoint an inspector.

Dundee.—At the beginning of the year it was estimated that the expenditure in the electricity department of the Town Council would amount to £5,362. 6s. 7d., whereas the actual expenditure was £5,874. 16s. 7d., a difference of £512. 10s. The income from electricity was estimated at £3 200; meter rents, £120—a total of £3,320, the actual income being £3,525 10s. 9d., and £168. 2s 11d., altogether £3,693. 13s. 8d., showing an increase on the estimate of £373. 13s. 8d. The electricity department accounts for last year were balanced by drawing £2,181. 2s. 11d. from the gas department. For the current year the income estimates are—for electricity £4,200, and for meter rents, £200, being a total of £4,400. The expenditure is expected to be £4 386. 14s. 4d , and it is therefore estimated that for the year ending April 30 next there will be a surplus of £13. 5s. 8d.

Fifeshire.—At a meeting of the Telephone Committee of Fife County Council on Tuesday Mr. William Patrick, clerk, intimated that the National Telephone Company had again refused to give the rent asked and the free use of instruments for the privilege of wayleave. Mr. Hugo Haig, the chairman, moved that the Council notify to Lord Balfour, the chairman, that unless the company give the terms that are asked by the Fife County Council the wires will be cut throughout the county within six days. This was unanimously agreed to, and the telephone company are to be notified accordingly. It is 18 months since the negotiations commenced, and the committee are exasperated at the delay. If the telephone company be successful in delaying a settlement for another month the telephone system will by that time be taken over by the Government, and Fife County Council might not then get any equivalent for wayleave.

Darlington.—The Board of Guardians have held a meeting at which the Workhouse Committee recommended that the telephone should be continued to the infirmary, so as to enable the night nurse to communicate direct with the doctor. This was agreed to. Mr. Bartlett suggested that the clerk's office should be put on the National Telephone system. He thought this would be a distinct advantage, as just recently he was prevented from communicating with the clerk in time to have some of the unemployed of the town put into positions in connection with the County Council. He moved that the matter be referred to the Workhouse Committee for consideration. The Workhouse Committee reported that Messrs. Cox-Walker had offered to connect the workhouse with the police office for £20. 4s. 6d. This was considered necessary for the purpose of raising an alarm in case of fire. The matter was referred back to the committee for consideration.

Surbiton.—The annual general meeting of the shareholders of the Assembly Rooms Company has been held, at which Mr. Coochey urged that as the mains passed within a few feet of the rooms the directors should have the electric light laid on. The Chairman said he was so much impressed with the desirability of having the electric light that he asked their manager to make enquiries, and he was at once met with the statement that the Corporation could not supply it beyond the borough boundary, and that the Surbiton Commissioners would not agree to their doing so. Mr. Harrison confirmed this, but Mr. Knapp said he was told that the Corporation had power to supply beyond their own area with the consent of the District Council. Mr. Moatt said the matter had never been before the Surbiton Council yet. The Chairman promised that the directors would consider the question, and he hoped to be able to give a favourable reply next year.

Brighton.—The Lighting Committee of the Brighton Town Council report that they have advertised for and received tenders for the supply of pillars, etc., for the electric light arc lamps proposed to be erected in certain streets of the borough. The tenders received for the 80 cast-iron and drawn-steel bracket posts for suspending electric light arc lamps are as follow: Pierson and Co., 124, Fenchurch-street, London. £3,680; Newton, Chambers, and Co, Limited, Sheffield, £2,640; Hart. Son, Peard, and Co., Limited, Birmingham, £2,600. Informal tenders for these posts were also received from Messrs. Macfarlane and Co., Messrs. Reed and Son, Messrs. G. Smith and Co, Messrs. Mackenzie Bros., Messrs. Baird, Son, Thompson, and Co., and the Alloa Iron Company. The committee recommend that the tender of Messrs. Hart, Son, Peard, and Co. be accepted. It was found that the tenders received by the committee for the supply of the 45 cast-iron upright posts, with bracketed canopies, required for supporting electric light arc lamps, need further consideration, and the committee have deferred their report until the meeting of the Council on 20th inst.

West Coast of America Telegraph Company.—The report of the directors for the year ended December 31 last states that the gross income for the year 1894 was £21,753, as against £15,096 in 1893, and in order to provide for the payment of the debenture coupons, it was necessary this year to take £10 400 from the reserve The sterling value of the local traffic for 1894 was again most seriously affected by the low rates of exchange, both in Peru and Chili, the value of the dollar in Chili having fallen as low as 10⅜d., and the average rate for the year was 12d., as against 14d. in 1893. In view of the recent legislation in Chili, by which the paper currency of the Republic is to be replaced from June 1 by gold, on the basis of 18d. to the dollar, it may fairly be hoped that exchange in the future will not greatly fluctuate from that figure. It may also be anticipated that the use of the telegraph for commercial purposes will continue to increase. The total expenses were £20 154, against £19,632 in 1893. The Company's cables and land lines, as well as the repairing steamer "Retriever," continue to be maintained in a state of efficiency, consistently with which every possible economy is practised with regard to the expenditure. The direct service between the Company's stations and Europe, *vid* Madeira, appears to have afforded every satisfaction to the public.

Cheltenham.—Mr. A G. Sanders, electrical engineer, Clarence-parade, has explained to the Electric Lighting Committee of the Town Council that several installations carried out by him in the town had not yet been connected with the mains, though most of them had been carried out some months back, and applications sent in. The Town Council resolved that the town clerk should write and thank him for drawing attention to the cases mentioned by him, which were receiving attention, and would be connected as soon as possible. Several extensions of the mains are projected, including a main from the works to the top of Bayshill, at an estimated cost of £1,300, extending along the Arle-road, Gloucester-road, and St. George's-road to the railway bridge there to branch in two directions—one to St. George's-parade, and the other up the Western-road, part of Christ Church-road, and along Lansdown-terrace. A letter from Messrs. David Midgley and Sons of 48, Princess-street, Manchester, was read by the Finance Committee, offering to lend to the Corporation a sum of £2 000 at 3 per cent, for a fixed term of five, seven, or ten years. It was resolved to accept Messrs. Midgley and Sons' offer on account of the electric loan for a term of 10 years, determinable by either party at the end of the fifth or seventh year by six months' notice in writing.

Islington.—The Vestry have held a meeting, at which a report was received from the Electric Lighting Committee, stating that in the erection of the central station it has been found urgently necessary to utilise a portion of the gardens of 19, 21, and 23, Burnard-place to enable the erection to proceed on that side of the site; and having regard to the nearness of such houses to the station, and to the fact that some cause of action against the Vestry may accrue in future by virtue of possible nuisances to the occupiers arising from the running of the machinery and other matters, and further, that as the sites of the houses will shortly be required for the purpose of extension it recommends that the offer of the tenant for life, his trustees and reversioners, to join and assign to the Vestry the outstanding leases of the above houses (the freehold of which the Vestry has already acquired subject to such outstanding leases), and to give vacant possession for the sum of £350 per house and vendors' solicitor's costs according to scale be accepted, subject to a good title being shown, and to one solicitor only being employed to represent the whole of the vendors. Mr. Lambert, in moving the adoption of the report, said they had purchased all the houses with the exception of No. 1. He considered that the purchase was a good bargain They had already purchased the freehold, and they now wished to acquire the leasehold for £350 per house. Mr. Goodman, in seconding, said the opinion of some of them was that in the market the houses would not be worth that money; but if he had not been a vestryman, he would have been glad of the opportunity of acquiring the leaseholds at the price it was proposed to pay for them. He hoped the Vestry would not lose the chance After some discussion, the motion was agreed to.

Tunbridge Wells.—The lady of the manor has agreed to allow the Pantiles to be included in the new electric light scheme. The engineer (Mr. Preece) has laid before the Lighting Committee of the Town Council estimates of the cost of constructing new transformer stations, and extending the mains along Mount Ephraim (from Mount Ephraim-road to the Grosvenor Fountain), in Monson-road, and in Calverley-road (from Camden-road to Mr. Howard's corner) amounting to £630. 10s. It was resolved that these extensions be approved, and that Mr. Preece be authorised to proceed with them at once. The question of the arrangements to be made for plans, showing how it is proposed to expend the £12,000 recently sanctioned by the Council for extensions, was discussed with Mr. Preece. It was resolved that Mr. Preece be engaged to prepare all plans and estimates, and to do all work required from the electrical engineer up to the obtaining of the sanction of the Local Government Board to the additional loan, including attendance at the public enquiry, and that he be paid for these services 2½ per cent. upon the amount of his estimate, it being understood that the total additional amount to be borrowed does not exceed £12,000, and also that in the event of the Council desiring Mr. Preece to undertake the superintendence of the carrying out of the works covered by the new loan

Digitized by Google

he will give the same services as he has done in respect of the present works for an additional 2½ per cent. on the amount expended. Councillor Wood intimated to the Town Council that private applications for the electric light were coming in rapidly from all parts of the town. The Mayor said doubtless before the winter season many residents would ask for the light. In reply to questions, Councillor Wood said the works were nearly complete, and the chief lamps had been fixed for use.

Luton.—A meeting of the Town Council has been held, at which the clerk informed the Council that the Mayor, Mr. Giddings, and himself had had an interview with the parliamentary agents in reference to the notice that had been lodged by the Luton Gas Company concerning the electric lighting order, and the understanding arrived at was that if the opposition or the application was not withdrawn the Corporation intended to go on with the matter, and they would be prepared to be examined by the Select Committee. Subsequently, he (the clerk) saw Mr. Phillips, the manager of the gas company, who stated that possibly the Corporation had misunderstood the purport of the notice. It was impossible for the company to appear before the committee unless they had given notice of opposition to the various clauses to which they took objection, and therefore they were compelled to give that notice in order to qualify themselves in that respect. He had explained to Mr. Phillips that he thought possibly he was not aware that the Board of Trade were preparing new regulations, based to a great extent upon the report made by Major Cardew on the explosions that took place in London, and, after a general conversation, Mr. Phillips wired his parliamentary agents requesting them to seek an interview at once with the agents of the Corporation. The result was that a telegram came to say that the opposition had been withdrawn, and therefore there was no occasion to appear before the committee. He thought it was due to Mr. Phillips that this explanation should be made. It was expected that the matter would be completed about the middle of this month. The Mayor thought the Council would agree with him that this was a very satisfactory conclusion of the matter. He thought the town clerk was to be commended for the tact and judgment which he had exercised, and which had saved what would probably have been considerable expense.

Consolidated Telephone Construction and Maintenance Company.—The directors, in their report for the year ended March 31st last, state that the operations for the past year show a manufacturing profit of £1,403. The amount available for disposal, after the usual provision for doubtful debts, etc., is £2,866, from which the directors propose to pay a dividend of £1. 10s. per cent., leaving a balance of £1,236 to carry forward. The competition (principally foreign) in the manufacturing business has continued with unabated severity, the selling prices of all articles having been largely reduced. The lease of the present factory terminates at Christmas next, and it is proposed, if suitable premises can be found, to remove the plant, machinery, etc., to the country, with the object of reducing the expenses of production, in the shape of labour, rent, and the heavy rates now being paid. Various manufacturing proposals have been submitted to the directors, one of which, for the manufacture of a unique form of battery and accessories, has been adopted, the Company having obtained the sole right to manufacture all supplies required by the patentees of the capsule battery for the whole period of the patent—viz, 14 years. It is proposed to alter the memorandum of association to enable the Company to manufacture other articles than those solely electrical, and a resolution will be submitted to that effect at the extraordinary general meeting. The directors are hopeful that this extension of business will be advantageous to the Company. The lawsuit in Belgium, undertaken, in conjunction with the Edison Gower-Bell Telephone Company, against infringers of the patent held by the Company, resulted in a successful appeal against the previous decision, and the Court has ordered a claim to be sent in for damages. The subsidiary company, the Anglo-Portuguese Telephone Company, continues to show satisfactory progress.

Medical Electrical Institute, Limited.—From the observations of the senior official receiver (Mr. C. J. Stewart), issued under a winding-up order recently made in this case, it appears that the company was registered on October 16, 1894, and was formed for the purpose of acquiring the business hitherto carried on by the Medical Battery Company, Limited, for the sale of medical and electrical appliances, etc. An order of Court had been made on November 22, 1893, for the winding up of the old company. Meetings were subsequently held of the creditors and shareholders of that company, which unanimously approved of a scheme of reconstruction, and on July 25, 1894, the Court sanctioned the scheme, of which the Medical Electrical Institute is the outcome. The registered capital of the new company was £75,000, of which £50,000 ordinary shares were to be issued as fully paid to the shareholders of the old company, while £25,000 preference shares, or such portion of them as might be required, were to be issued to the unsecured creditors of the old company in accordance with the admission of the proof of such creditors by the official receiver. On October 17, 1894, Mr. C. B. Harness, who had previously been the managing director of the old company, was appointed manager of the new company at a salary of £600 a year. It subsequently became apparent that the new company was not in a position to carry out the terms of the scheme of reconstruction, and in January last Mr. Ernest Hart was appointed by the Court receiver for debenture-holders and is understood to have been since that date in possession of all the company's assets. Upon the commencement of business by the new company, advertisements seem to have been inserted in various newspapers upon a considerable scale in the hope that as a result the demand by the public for the medical and electrical appliances sold by the company would greatly increase it appearing that the former prosperity of the old company was in a large measure due to a system of extensive advertising. In this hope, however, the Board were disappointed, and the secretary states that the advertisements did not produce sufficient business to pay expenses. The official receiver observes that it will be seen from the accounts that, after paying the costs of liquidation, the margin of cash left for working capital was only about £1,000 The statement of affairs shows liabilities £11,614, of which £5,472 are unsecured, with net assets nil. The failure of the company is attributed to loss on the trading and to the want of funds to carry on the advertising for such a length of time as might possibly have rehabilitated the business

Elmore's German and Austro-Hungarian Metal Company.—The directors, in their report to December 31 last, state that the accounts call for little remark, as the figures have changed but little from those of 1893. The second debentures have been reduced from £49,480 to £25,980 by redemption. The terms of the redemption were very favourable to the Company, and the great reduction of the capital was carried out at a cost of only £11,750, and this in preference shares. The amount advanced to the Metal Company by this Company is now £15,947. As security for the amount, this Company holds two mortgages upon the property amounting together to £15,000 which are a first charge, subject only to the payment of the balance of the final instalment of the purchase-money. With regard to the Metal Company's accounts, these also call for but little remark, the principal alterations in the figures being the additions and improvements to buildings, machinery, and plant, the increase in materials and stores in hand, and the increase of amount due from sundry debtors. The amount due to sundry creditors is somewhat large, owing to the amounts payable to contractors on account of the new plant. The directors regret that the amount standing to the debit of profit and loss account (£19,909) has increased. This is to a considerable extent caused by the heavy depreciation account, which has been deducted as heretofore. The directors are glad to report that although the new plant was not completed until the end of 1894 the sales had increased from £3,194 in 1893 to £8,130 in 1894, and that the loss on factory account was practically nil. It must be borne in mind that the working of the company was greatly restricted by want of funds during the early part of the year. With regard to the general work of the factory to date, the directors are able to report satisfactory progress. The new plant has proved to be of great value, and is a marked improvement upon the plant originally erected. The rate of progress has not been so rapid as the directors could have wished, delays having occurred owing to the severe frost, an accident to the drawbench, and other causes, which have seriously retarded work. Notwithstanding all this, however, the sales are over three times as great as for the same period last year, and the directors see no reason why the rate should not now increase to a much greater extent. The number of customers increase weekly; indeed, the directors find the question of orders the least difficult to deal with, as, although they do not advertise and have no travellers, they are in receipt of an abundance of good paying orders. They are also able to report that the Company has entered into further contracts for the supply of copper tubes, including one with the Imperial State Railways. The directors propose later to still further increase the number of tanks in the factory This can be done at a nominal cost, and will greatly increase the earning capacity of the factory.

PROVISIONAL PATENTS, 1895.

MAY 27.

10334. **An improved arrangement of electric call or sounding apparatus.** William Arthur Price, 6, Bream's-buildings, Chancery-lane, London.

10359. **Improvements in carriers for shades and like objects for gas and electric light fittings and the like.** Edward William Lancaster, Albert Works, Graham-street, Birmingham.

10360. **Improvements in tumbler switches for electric circuits.** Edward William Lancaster, Albert Works, Graham-street, Birmingham.

10366. **A new or improved electrical stage effect and appliances therefor.** David Alexander and Claud Hamilton, Limited, 70, Wellington-street, Glasgow.

10418. **Improvements in or connected with time-recording apparatus for consumption of electric current.** Robert Wende, 27, Karlstrasse, Berlin.

10433. **Improvements in dynamo-electric generators and motors.** George Edensor Dorman, The Hawthorns, Newport-road, Stafford.

10445. **Improvements in apparatus for electrolysis of alkali salts with quicksilver as cathode.** Henrik Christian Fredrik Störmer, 77, Chancery-lane, London. (Complete specification) (Date applied for under Patents, etc., Act, 1883, Sec. 103, November 26, 1894, being date of application in Norway.)

10480. **Improvements in methods of supplying electricity to arc lamps.** Arthur Wright, 26, Park-crescent, Brighton,

Digitized by Google

10448. **Improvements in secondary or storage batteries.** Lius Falero and Henry Lumley, 24, Southampton-buildings, Chancery-lane, London.

MAY 28.

10502. **Improvements in movable pendants and brackets for suspending and carrying electric, gas, or oil fittings and for other purposes.** Edward William Lancaster, Albert Works, Graham-street, Birmingham.

10518. **A self-contained electrical grinding machine.** Cecil Fane, 98, Leadenhall-street, London.

10535. **An automatic device for use with electric motors.** Cecil Burman Callow and Henry Justus Eck, 13, Burnaby-gardens, Chiswick, London.

10536. **An automatic device for starting electric motors.** Cecil Burman Callow and Henry Justus Eck, 13, Burnaby-gardens, Chiswick, London.

10538. **Improvements in dynamo-electric generators and motors.** George Edensor Dorman, The Hawthorns, Newport-road, Stafford.

10539. **Improvements in dynamo-electric generators and motors.** George Edensor Dorman, The Hawthorns, Newport-road, Stafford.

10569. **Improvements in electrical apparatus for lighting gas.** Eugene Massy, 65, Chancery-lane, London.

10587. **Improvements in and relating to electric heaters.** Charles John Reed, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

MAY 29.

10604. **Improvements in insulators or insulated connections for telegraph, telephone, and other electrical wires.** Richard Taylor, 24, Temple-row, Birmingham.

10614. **Improvements in or relating to electric telephone systems.** Thomas Sloper and George Edmund Beckett, 14, Brittox, Devizes.

10647. **Improvements in the electrical propulsion of boats and vessels.** Anthony George New and Arthur James Mayne, 55, Chancery-lane, London.

10655. **Improvements in and connected with arc electric lamps.** Gustav Binswanger and Arthur Ernest Angold, 73, St. Stephen's-road, Upton Park, London.

10656. **Improvements in and connected with arc electric lamps.** Gustav Binswanger and Arthur Ernest Angold, 73, St. Stephen's-road, Upton Park, London.

10660. **Improvements in or relating to electric contact makers.** John Dudley Stuart, 4, Guildford-crescent, Cardiff.

10672. **Improvements in apparatus for measuring or indicating the frequency of alternating or pulsating electric currents or potential differences.** Albert Campbell, 34, St. George's-square, Regent's Park, London.

10679. **Improvments in or connected with furnaces or apparatus in which materials are fused by means of an electric arc.** Donald Barns Morison, 46, Lincoln's-inn-fields, London.

MAY 30.

10685. **Improvements in electrical thermometers.** George Chandler Whipple and Henry Ellis Warren, 55, Chancery-lane, London. (Complete specification.)

10687. **Improvements in the arc striking and feeding devices and arc lamp frames, more especially applicable to those arc lamps used singly or two or more in series across incandescent or constant-potential mains** Frederick D'Artrey Goold, South-Western Hotel, Woking, Surrey.

10746. **Improvements in or relating to the connecting and disconnecting the sockets of incandescent electric lamps.** Percy Benham and Walter Smith, 323, High Holborn, London.

MAY 31.

10778. **Improvements in dynamos and motors.** John Perry, 31, Brunswick-square, London.

10779. **A new method of and apparatus for the conversion of heat energy into mechanical energy and into electrical energy.** Frederick Hamer, 266, Camberwell New-road, London.

10792. **An improved dry battery for electrical purposes and material for packing same.** William Elliott, 75, Philip-lane, Tottenham, London.

10810. **Improvements in electric tramways.** Rookes Evelyn Bell Crompton, 55, Chancery-lane, London.

10816. **Improved method of installation for electrical conductors within buildings, and cases and appliances therefor.** Henry William Handcock, Alfred Herbert Dykes, and Robert Samuel Lloyd, 28, Southampton-buildings, Chancery-lane, London.

10817. **Improvements in joint blocks or boxes for electrical conductors and the combination thereof with the conductor casings.** Henry William Hancock, Alfred Herbert Dykes, and Robert Samuel Lloyd, 28, Southampton-buildings, Chancery-lane, London.

10836. **Improvements in storage batteries.** Clément Payen, 47, Lincoln's-inn-fields, London. (Complete specification.)

NOTES.

Swedish Incandescent Lamp Duty.—It is stated that the Swedish Customs duty on incandescent lamps has been raised by about 40 per cent.

Electrical Exhibition at Carlsruhe.—The Grand Duke of Baden has consented to become a patron of the electrical exhibition which is to be held at Carlsruhe in September next.

Rating of Machinery.—Mr. Heneage has given notice on the third reading of the Rating of Machinery Bill to move that the Bill be recommitted to a committee of the whole House.

Electric Omnibus Service.—It is announced that in the course of a few weeks a service of omnibuses, propelled by means of electricity, will commence running between Liverpool street and Hammersmith.

"Vibration of a Battery."—On Tuesday, among the applicants at Greenwich Police Court was a man who said his neighbour had an electric battery, and the vibration was such that he could get no sleep. Mr. Kennedy told him to consult a solicitor.

Society of Arts.—The conversazione of this society will take place at the South Kensington Museum on Wednesday next. The reception will be held by Major-General Sir John Donnelly, K.C.B, chairman, and the members of the council of the society from 9 to 10 p.m.

Obituary.—The Nestor of German physical science, Wirklicher Geheimer Rath Professor Dr. Franz Neumann, recently died at Königsberg at the age of 97. One of his most noteworthy publications was "The Mathematical Theory of Induced Electric Currents," which appeared in 1845.

Book Received.—We have received from Signor Ulrico Hoepli, 59-63, Galleria De Cristoferos, Milan, a copy of "Manuale di Magnetismo ed Elettricità," by Signor Guiseppe Poloni, late professor of physics at the Modena University; second edition, edited by Signor Francesco Grassi, professor of physics at the Society for the Encouragement of Arts and Trade, Milan.

An Anachronism.—In "Harold," the opera composed by Mr. F. H. Cowen, which was produced at Covent Garden Theatre on Saturday last, Harold takes the oath on the relics of a saint in the monastery at Bayeux, the relics being illuminated with the electric light. It has hitherto been generally supposed that the electric light was unknown in the eleventh century, but Sir Augustus Harris knows better.

Royal Meteorological Society.—At the ordinary meeting of the society, to be held by permission of the council of the Surveyors' Institution, at 12, Great George-street, Westminster, on Wednesday, the 19th instant, at 7.30 p.m., the following papers will be read: "Hourly Variation of Sunshine at Seven Stations in the British Isles," by Mr. Richard H. Curtis, F.R.Met.Soc., and, "The Frequency, Size, and Distribution of Hail at Sea," by Mr. Henry Harries, F.R.Met.Soc.

Electric Railways in Japan.—Russia, in return for a certain political service, is just now placing large shipbuilding and machinery orders in France; but Japan does not seem to recognise help from Great Britain in a similarly substantial manner, for German papers announce that the Allgemeine Elektricitäts-Gesellschaft has received a commission from Tokio for electric railway material to the value of several thousands of pounds, and the placing of a second large contract with the same firm is, it is said, imminent.

Loughborough.—In the recent examinations arranged by the local Technical Education Committee, the number of students attending were as follows: geometry, 59; light and shade drawing, 9; model drawing, 11; freehand drawing, 6; hosiery, 12; preliminary electric lighting, 6; perspective, 3; machine construction and drawing, 16; building construction, 11; ordinary and honours electric lighting, 16; mathematics, 73; magnetism and electricity, 54; chemistry, 71; steam, 7; applied mechanics, 8 total, 413.

Personal.—For the appointment of principal of the Wandsworth Technical Institute 134 applications were received, and, subject to confirmation by the Technical Education Board, the governors have elected Mr. William Thomas Allder Emtage, M.A., formerly of Pembroke College, Oxford, to the post. Mr. Emtage is at present professor of mathematics and physics at University College, Nottingham, where he has entire charge of the physical laboratory and superintends the construction of electrical appliances by the engineer students of the college.

New Process of Extracting Gold.—A new process of extracting gold from its ore has been devised by Mr. C. Lorsen. He electrolyses a solution of bromide of potassium and thereby obtains an alkaline solution which contains hypobromide and bromate, which is capable of dissolving gold. The ore is treated with an excess of this solution by rotating cylinders. The solution is then filtered, the gold precipitated by passage over a mixture of iron and coal, and the solution, which now contains bromide of potassium mainly, is once more electrolysed, and again used for extraction.

Electric Lighting of Barracks.—On Tuesday in the House of Commons, in answer to Sir D. Macfarlane, Mr. Campbell-Bannerman said that barrack-rooms were not always crowded. No direct comparisons as to improved health from electric light instead of gas had, so far as he was aware, been made, although the advantages of the electric light were undoubted. Offers to supply the electric light to barracks been made and declined, for the present, at Great Yarmouth and Dover. A succession of experiments in electric lighting had been approved, and plans for providing the light in Colchester hospital and Cambridge lines, Woking, were in progress.

American Institute of Electrical Engineers.—At the annual meeting of this institute the following officers were elected: President, Louis Duncan, Baltimore. Vice-presidents: M. I. Pupin, New York; W. F. C. Hasson, San Francisco; Angus S. Hibbard, Chicago. Managers: Carl Hering, Philadelphia; B. J. Arnold, Chicago; Chas. F. Scott, Pittsburg; Cary T. Hutchinson, New York. Treasurer: Geo. A. Hamilton, New York. The council reported a membership of 944, showing a net gain of 144 members for the year ended April 30 last. The general meeting is to be held at Niagara Falls from the 25th to 28th inst. inclusive.

Railway Development in Russia.—A St. Petersburg telegram states that the special committee which was sent by the Russian Railway Administration to Great Britain, France, Germany, Switzerland, Holland, and Belgium to study the electric railways and latest improvements in electric transit in those countries has just returned to Russia. M. Gortihakoff, the engineer, who is president of the committee, has submitted a detailed report to the Emperor on electric locomotives and the English electric brake. His Majesty endorsed on the report, in his own hand, the following remark: "Very interesting, and desirable to be introduced in Russia, taking the English railways as models."

Digitized by Google

Electric Sugar-Refining.—Experiments made by Herr Dammeyer in the sugar mills at Ottleben in refining by means of electricity seem to have resulted satisfactorily, according to the *Elektrotechnische Zeitschrift*. The analysis of the resulting product when electricity was used, with an admixture of 2 per cent. of lime, was: sugar 89 per cent., other organic substances 3·67 per cent., salts 2·65 per cent., water 4·98 per cent. Another experiment, without electricity being employed and with an admixture of 3 per cent. of lime, gave: sugar 86·8 per cent., other organic substances 4·31 per cent., salts 3·31 per cent., water 5·58 per cent. In the electric process there was also a gain in by-products, and crystallisation took place quicker.

Canadian-Australian Cable.—Mr. J. S. Larke, the Canadian commissioner who is now in Sydney, has laid before the Chamber of Commerce there a scheme, which has the support of the Canadian Government, for the laying of a cable between Canada and Australia by the Governments of Great Britain, Canada, and the Australian Colonies. The cost of the cable is stated at £1,600,000, and it is proposed to borrow this sum at 2½ per cent. Mr. Larke states that, placing the charge for cabling at 2s. a word, if the cable secured half the present business it should be able to pay off the whole of the capital outlay and meet an annual expenditure of £125,000 by the year 1919. The Chamber of Commerce will consider the scheme at a special meeting.

"Patenting Made Easy."—Messrs. Iliffe and Son, St. Bride-street, send us a pamphlet under this title from the pen of "A Registered Patent Agent." It is a useful little publication. The author explains that between 15 and 20 per cent. of the applicants for letters patent put such absurd titles to their applications, as shown by the *Official Journal*, that the specifications must be by analogy inaccurate and useless, giving much trouble to the Patent Office authorities and vexation to the inventors. Since these persons would under no circumstances have employed a patent agent, the effect of a perusal of the book will, the author hopes, enable them to put the work in proper form, and, while securing their own interests, save the Patent Office a world of trouble.

Royal Society Conversazione.—The second conversazione, or ladies' soirée, of the Royal Society was held at Burlington House on Wednesday. There were but few electrical exhibits, but a practical demonstration was given by the Postmaster-General of the telephonic communication between London, Edinburgh, Glasgow, Belfast, and Dublin. Mr. A. P. Trotter showed graphically the behaviour of the electric arc under varying condition of volts and amperes. The magnetic tester of Prof. Ewing, for the measurement of hysteresis in iron, was exhibited, as was an improvement by Prof. Roberts-Austen of his electrical furnace. There was also on view Lord Armstrong's collection of photographic prints of various forms of electric discharge in air, without and without applied induction.

The British Association.—The British Association spent a very enjoyable time in Canada in 1884, and the Canadians are putting forward every inducement to bring about another Transatlantic meeting in 1897. Montreal had her turn in 1884, and Toronto, as the rival commercial city of Eastern Canada, is now suggested as the place of meeting. The Dominion Government promises £4,000, and we may be sure that every Canadian railway and steamship corporation would, despite bad times, place its lines at the disposal of the visitors. It is a pity, perhaps, says the *Daily Chronicle*, that if there is to be a colonial meeting every decade the colonies could not be visited in turn; but neither Australia nor South Africa have come forward, and so we may hope that the generous invitation from Canada will be accepted.

Tramways in Paris.—"A very careful and complete report," so designated by the British Ambassador at Paris, has been drawn up by Mr. Graham, one of the secretaries of the Embassy, upon the tramway system of Paris and the Department of the Seine, and has been issued as a parliamentary paper. In forwarding this report to the Earl of Kimberley, the Marquis of Dufferin refers to the fact that it was desired for the information of the London County Council. The report states that a large proportion of the lines is worked by animal power, but mechanical power is making rapid strides. Compressed air furnishes the motive power on the line between the Louvre and St.-Cloud, and on all the lines of one of the companies. Electricity is employed for cars running from the Opera to St.-Denis. The Belleville funicular tramway is worked by an endless cable setting all its cars in motion, and propelled by stationary engines.

Electricity in Bosnia.—On May 1 an electric tramway, 3½ miles long, was opened in the Bosnian capital, Serajevo or Bosna Serai, which has a population of 50,000. The current is supplied through overhead wires, after the patent of Messrs. Siemens and Halske, of Vienna, who built the line. The wires are suspended on artistic iron poles, on simple wooden masts, or on wall hooks, according to the class of street through which the line passes. In many cases the poles also serve to carry the electric lighting cables. The return takes place through the rails. Five motor-cars have been ordered in the first place, and an electric locomotive is being constructed for goods traffic purposes. The tramway obtains its current from the central station in Serajevo, which, simultaneously with the tramway, has been built by the Bosnian Government. In this station there are at present three boilers and three horizontal compound steam-engines, each of 150 e.h.p., and each driving by ropes two Siemens dynamos. One of these dynamos, of a capacity of 75 h.p., suffices for the supply of current to the tramway, at a pressure of 300 volts, the same as for the electric lighting, which is on the three-wire system.

Executions by Electricity.—The *Family Doctor*, a periodical which was started by the same gentleman who evolved that highly aristocratic organ the *Illustrated Police News*, has now taken up the subject of electrocution, and commits itself to the following astounding assertion: "It can scarcely be a pleasant reflection to physicians who have examined the victim of electrocution to realise that they have probably been operating upon a person who was merely physically stunned. There is nothing that goes to show that death took place in the case where men have suffered the penalty of the law in the electric chair. It has been proved that the mind may be quite as active during such periods as at any other, and the thoughts of the victim when the surgeons are cutting him up must be anything but agreeable. After all, while it has its elements of brutality, the old fashioned neck-breaking process of hanging may have points of grace, and is, perhaps, much more sure as a method of taking life than any of the more modern inventions. The guillotine had its compensations, and it might be revived rather than take the risk of the half-way process that the electric current as now applied may be guilty of." It is almost needless to say that the paper in question has no authority for its statement.

French Submarine Cables.—A Dalziel telegram from Paris on Friday last stated that strenuous efforts are being made by the French Colonial Party to force the Government to introduce an extensive system of submarine cables in order to avoid having to depend upon the English

Digitized by Google

lines in case of war, a necessity which is declared to be a great national danger. It is now stated that considerable opposition will be offered before the Budget Committee to the renewal of the subventions paid to the English cable companies, of which the principal are the Spanish Submarine Telegraph Company, 1,700,000f. a year for the cable to Senegal; the Eastern Extension Company for Saigon and Tonquin, 300,000f.; the African Direct Telegraph Company, for the West Coast of Africa, 300,000f.; and the Eastern Telegraph Company, the short line from Obock to Berlin, 37,500f. It is contended that this money should be devoted to founding French cable companies. The *Débats* has an article urging the Government to at once lay down telegraphic cables to all the principal parts of the world in order to make France independent of the English lines in time of war. It asserts that Spain, Portugal, Germany, and Holland would be only too glad to transfer their custom to French wires in order to break down the British monopoly.

Light Railways Bill.—On Monday, in the House of Commons, Mr. Bryce formally moved the second reading of this Bill. Mr. Strachey moved an amendment declaring "that so long as light railways are constructed and maintained by Imperial subventions in Scotland and Ireland, no Bill for the construction of light railways in England will be satisfactory which does not provide for like assistance from the Treasury." In support of his contention the hon. member referred to a letter which appeared a short time ago in a daily paper from the general manager of the Belfast and Northern Counties Railway, who had said he was "not sanguine of light railways in England if left to the railway companies and local subscriptions, even though the Board of Trade may make reasonable concessions." The agriculturists of England, the hon. member contended, ought to be treated as generously as their fellows in Scotland and Ireland. Mr. Grant Lawson seconded the amendment. The hon. member was speaking at midnight, when the debate stood adjourned. The debate was resumed on Tuesday on the amendment. Mr. Lawson, who was interrupted on the previous night by the 12 o'clock rule, continued his speech in seconding the amendment, and commented upon the fact that the Bill did not define what was a light railway. Mr. P. Smith thought that the Bill presented a good many difficulties in its financial aspect and otherwise. The hon. member was still speaking at 12 o'clock, when the debate stood adjourned.

Leeds Association of Engineers. — The members of this association have visited the central electric lighting station of the Yorkshire House-to-House Electricity Company, and inspected the recent extension of the plant. Two 400-i.h.p. horizontal compound condensing Corliss engines, with cylinders 19in. and 36in. in diameter by 3ft. stroke, have been added, built by Messrs. Hick, Hargreaves, and Co., of Bolton, and fitted with their high-speed gear. Each has a flywheel 17ft. in diameter, weighing 18 tons, from which is driven by means of ropes a 200-kilowatt Hall dynamo of the multipolar alternating-current type, having seven tons of revolving magnets, and sectional armature. The dynamos work with remarkable smoothness. The total power capable of being developed by all the dynamos is 700 kilowatts, but the foundations are nearly finished for another 400-h.p. engine by Messrs. John Fowler and Co., Leeds, fitted with the Marshall-Wigram gear, which will raise the total electrical power to 900 kilowatts. The working pressure in the mains is 2,000 volts, and the dynamos are self-regulating within about 15 per cent. The company began business about two years ago, with 4,000 lights on circuit, and they have now 26,000 8-c.p. lights. The boiler-house contains six Lancashire boilers, 30ft. long by 8ft. diameter, having mechanical stokers, feed-water heaters, etc., and each capable of evaporating 8,000lb. of water per hour from 212deg. F. About 40 members were present on the occasion, and expressed themselves greatly pleased with the installations.

Electrical Trades Section.—A meeting of the Electrical Trades Section of the London Chamber of Commerce was held on Tuesday last to further consider regulations and conditions for securing the safety of the public, and for ensuring a proper and sufficient supply of electrical energy, made by the Board of Trade under the provisions of the Electric Lighting Acts 1882 and 1888, together with observations made by members of the section in reference thereto. Mr. Emil Garcke occupied the chair. It was stated that a letter had been received from the Lord Chairman of Committees of the Houses of Parliament (in reply to a communication from the section) stating that the protective clause would be introduced in all Electric Traction Bills. A letter had also been received from the Board of Trade extending the time for receiving suggestions about the new regulations to the 15th inst. After some conversation as to the course of procedure to be adopted, Mr. Wright said that a committee of the Institution of Electrical Engineers had drawn up a complete set of regulations, in which very radical alterations had been made on the new Board of Trade regulations and a number of unworkable rules had been excised. A meeting of representatives of the London electric light companies was also to be held that day to consider the same matter. It was decided that the section should go into the matter in committee, the proceedings being private. It was agreed that it was advisable that a joint recommendation should be made by the section, the Institution, and the companies.

Early Atlantic Cable Men.—A special meeting of the New York Chamber of Commerce has been held to witness the ceremony of the presentation to the Chamber of the picture commemorative of the work of the late Cyrus W. Field and his associates in laying the first cable under the Atlantic Ocean. The presentation of the picture was made by Mr. Morris K. Jesup, one of the vice-presidents of the Chamber and chairman of the committee appointed to secure the memorial; his associates being Messrs. Abram S. Hewitt and W. E. Dodge. The picture represents a meeting of the Atlantic cable projectors at the residence of Mr. Cyrus W. Field in Gramercy Park. Mr. Peter Cooper is presiding. Mr. Field is calling attention to a chart of Trinity Bay, pointing to Heart's Content as a safe harbour for landing the cable. Mr David Dudley Field stands by the president with a lawbook. Mr. Chandler White is handing estimates of expense to Mr. Marshall O. Roberts, next to whom, at the table, is Mr. Moses Taylor, listening to Mr. Field's argument. Near Mr. Taylor, at the end of the table, stands Mr. Wilson G. Hunt, who, though he joined them some time after their first organisation, remained a staunch supporter of the project to the end. Prof. Samuel F. B. Morse is standing behind Mr. Roberts, and by his side is the artist, Mr. Daniel Huntington, sketching. The picture is life-size, the canvas being 9ft. long by 7ft. in height. The list of donors includes the estates of Peter Cooper and W. G. Hunt, the Gould brothers, the Western Union Company, the Dodge family, Cornelius Vanderbilt, J. P. Morgan, and about 50 others.

Equipment for Electrical Engineering Laboratories.—A paper on this subject was read some time ago before the Society for the Promotion of Engineering Education by Mr. Dugald C. Jackson, professor of electrical

Digitized by Google

engineering at the University of Wisconsin, U.S.A., and he now sends us a reprint of the same in pamphlet form. After dealing with the various apparatus required, he points out that in determining the course of study to be pursued by the electrical engineering undergraduate, upon which the course of laboratory work must depend, it must unfortunately be remembered that he cannot confine his attention to electrical engineering during the whole time given to professional work in his course. He must gain an elementary but practical knowledge of thermodynamics and hydraulics with an efficient knowledge of their application in steam and water power plants. He must also get a common-sense knowledge of the principles underlying the design, manufacture, and selection of machinery. In fact, he must receive a good working knowledge of the problems of the mechanical engineer. Laboratory courses are likely to fail when not properly balanced on account of a failure to educate the common sense or judgment of students, and the students leave the college without having gained an all-round capacity for practical work and research, which is necessary to put them in a fair way to become useful engineers. The knowledge of the electrical engineer must be based on the honest, well-tried mechanical laws, and he must go into a study of all that will aid most in putting him in the way to make a thorough electrical engineer.

London County Council Scholarships. — The Technical Education Board will proceed in July next to award five of its valuable Senior County Scholarships. These scholarships, which are reserved, as a rule, for young men and women under 19 years of age, are intended to enable promising and deserving students, who would otherwise be unable to afford the expense, to go through a three years' course at a university or at a technical institute of university rank. They are limited to those candidates whose parents are in receipt of not more than £400 a year. The scholarships not only give free tuition, but also a money payment of £60 during each of the years that the scholarship is tenable. They are primarily intended to encourage the pursuit of some branch of science, art, or technology; but they may also be awarded for the promotion of studies in modern languages or other branches of education. Four of the scholars who were appointed last year are studying science or engineering at University College, London; Sidney Sussex College, Cambridge; the Durham College of Science, Newcastle; and the City and Guilds Institute in Exhibition-road. The fifth, a lady, is studying at Bedford College. In making the award the Board takes mainly into account the record of each candidate's past career and distinctions, and the evidence as to ability, industry, and good character, which the candidate is able to supply. At the same time it reserves the right to apply any examination test that it may think fit. Full particulars may be obtained from the secretary of the Board, at 13, Spring-gardens, S.W. Candidates should send in their names not later than the 29th inst.

Cable Stations.—We have received the June issue of the *Windsor Magazine*, which, among other interesting matter, contains an article by Mr. Roland Belfort, entitled "At an Atlantic Cable Station." It deals with the Commercial Cable Company's Hazel Hill Station, Nova Scotia. The writer points out: "Though the receipts from the cable are good, the expenses are very heavy. The costly transmitting stations in Canada and Ireland do not earn a penny directly. The cables average £250 per mile, the delicate instruments cost from £50 to £200 each, the expenses of executive management amount to about £10,000 per annum, the managers draw from £500 to £800 per annum. The stations being 3,000 miles apart, travelling expenses form a serious item. Repairing expeditions are ruinous; £35,000 was sunk in one expedition that failed, another ship had to be employed at £500 per day. Cables break. Four were broken down simultaneously by an extraordinary seaquake — a violent submarine eruption; whales get entangled with them. Once a schooner settled down on one and broke it. Ships' anchors break cables in shallow water; fishermen bent on a 'catch' will drag for a cable, hook it, and then claim compensation for not having cut it to save their anchor and chain! On one occasion a cable was wilfully cut off Newfoundland. The culprits were strongly suspected, but conviction would have been difficult and costly. Cables have been buried for miles in submarine ravines and lost. Even the landing rights in France cost this company £8,000 and three months' tedious negotiations. They got similar facilities in England for £1, and a polite letter to the Board of Trade! The repairing ship cost £60,000, and often absorbs £500 per month to maintain her ready for sea at a moment's notice."

Electric Traction in India.—*Indian Engineering*, which ought to know better, in advocating steam traction for the Madras tramways, commits itself on the subject of electric traction to the following opinions, which contain a large proportion of unjustifiable assertions: "The flatness of Madras is all in its favour for laying tramways; the inhabitants being scattered over a considerable area, or some 30 square miles, makes it a relatively somewhat costly matter. Coal also has to be brought a long way and firewood is scarce. Under these circumstances an electric system of propulsion, in which fuel would be used to generate electricity, and the latter be distributed over lengthy strains of wire to deliver a percentage of the original horse-power (and at, of course, an enormous wastage of it), would be about the last to commend itself to the cautious investor of his shilling-rupees. Insulated wires put at the ground level readily dissipate the current, and both guttapercha and indiarubber are as sensitive to the Indian climate as the European constitution. The first cyclone must, on the other hand, flatten the whole network of overhead wires, which are as complete and airy as a cobweb; so that there is nothing except the rails and cars left which is not, in the case of electric power being employed, at hourly risk of breaking down or perishing. All the circumstances of Madras point to a steam tramway of some kind. . . . If the shareholders of the Madras Electric Tramway were to get direct steam traction adopted without the profitless intermediary of a host of silk *(sic)* and guttapercha covered wires, they might even yet find themselves in possession of a very valuable property." These remarkable utterances prove that the hymn which asks for the inhabitants of "India's coral strand" to be delivered from "error's chain" is not unjustified.

Property and Income Tax.—The Income Tax Adjustment Agency, 12 and 13, Poultry, E.C., write to us as follows: "With the income tax standing at a rate equal to $3\frac{1}{3}$ per cent. on one's income, it is of importance not to neglect to obtain all the relief in one's power. May we, therefore, be permitted to remind your readers that if for the last three years' trading the average of their profits was less than the amount on which they paid tax for 1894-5, they should at once claim repayment of the sum overpaid, otherwise they may lose their right to do so. If the profits of the last year exceeded the average (including the year) they cannot obtain any refund. By appealing now the assessment for the ensuing year will be settled also, as the assessment as amended for 1894 5 will in most cases stand good for 1895 6. A claim to set off a loss made

Digitized by Google

in farming or business against profits or income from any other source should be made immediately, while farmers claiming a return of tax paid under Schedule B by reason of their profits being less than the amount they have paid on must lodge their claims before July 6. Persons whose incomes from all sources for the year 1894-5 did not exceed £160 are entitled to exemption, those whose income did not exceed £400 to an abatement of £160, and those whose incomes did not exceed £500 to an abatement of £100. Claims for exemption or abatement may with few exceptions still be made in respect of the years 1892-3 and 1893-4, even when the income is said to be 'free of income tax,' where the incomes did not amount respectively to £150 or £400, as also for tax on life insurance premiums. The amount recoverable on abatement alone for the three years amounts to £11. 16s. 8d. A wife's income derived from a profession, employment, or vocation, where the joint income did not exceed £500 for 1894-5, is to be dealt with separately, the effect of which may be to give two abatements off the joint income, when the tax recovered for 1894-5 alone would amount to £10. 13s. 4d."

American Electro-Therapeutics.—There appears to be a "boom" in electro-therapeutics on the other side of the Atlantic, which is conspicuous by its absence on this, says the *Lancet*. Nor is it a mere fashion of the day; there is solid work behind it. The American Electro-therapeutic Association is evidence of this. Established on the usual lines of other medical societies, this association presents one very exceptional feature. The fellows "shall either be practitioners of medicine of good standing or electrical experts." The wisdom of such a rule may be open to question, but its aim is obvious and its intention excellent. It proclaims a due recognition of the principle that in electro-therapeutics "the physical problem underlies the biological one," and its object is to attain a higher standard of medical education in the physics of electricity. The annual report of the society's transactions for 1894 does not seem yet to have reached this country, but in 1893 the association consisted of about 80 fellows. Its various committees then submitted reports on standard coils, standard meters, static machines, constant-current generators and controllers, electrodes, etc. The latter committee appears to be a standing one, and furnishes an example of painstaking and methodical work. Its chairman has addressed a circular which now lies before us, "to every manufacturer of electro-therapeutic apparatus whose address is known" in order to secure "the universal adoption of uniform connections, a standard gauge of screw throughout construction, and efficient, durable, simple, and interchangeable electrodes." The report of this committee and the discussion thereon will form part of the proceedings of the society at its meeting in Toronto on September 5. Such a committee has much useful work before it. If in electro-therapeutics results are to be compared and a definite procedure followed, there is an evident necessity for the use of electrodes of a definite size and shape, easily procurable, and with distinctive designations. It is evident, for example, that a current strength (intensity) unbearable through an electrode of a certain size may be easily and painlessly passed through one of a greater surface area. It is long since the necessity for standard electrodes was recognised and advocated by Erb. Important steps in this direction were taken at the society's meeting two years ago, and it was also recommended on that occasion that all connections be by "standard hole and pressure screws." The adoption of this simple detail would "soften the lot and sweeten the temper" of many a practitioner sorely tried by the treacherous and even dangerous insecurity of certain "plug and socket" connections.

Telephone Trunk Lines.—The first and most important stage in the establishment of a telephone system for the United Kingdom in conjunction with the Post Office was completed on Wednesday, when the great trunk lines erected by the Department were inaugurated, and London was for the first time put into telephonic communication with Edinburgh, Glasgow, Belfast, and Dublin. The work has been carried out on the principles contained in a Treasury minute, dated May 27, 1892, when the late Government proposed that the operations of the licensed telephone companies should be confined to towns or defined areas, the trunk lines being worked by the Post Office. The details of the arrangement with the private undertakings for the transfer of their property are still the subject of an investigation by a Parliamentary Committee, but the Department has made ready to take over the working of the independent concerns by erecting the vertebrate system to which they will be attached. The most easterly wire from London runs to Ipswich, by way of Chelmsford and Colchester, and the most southerly to Brighton, two wires being used in each case. The Midlands are served by a line of from sixteen to four wires, passing through Nottingham, Sheffield, and Leeds, to Newcastle, and feeding Derby, Birmingham, and Leicester from Sheffield and Nottingham; Manchester and Liverpool, on the one side, and Hull on the other, from Leeds; and Hexham and Morpeth from Newcastle. At Birmingham the line is taken south-west to Newport, Cardiff, and Swansea, and, by another network, to Bristol, Exeter, and Plymouth. At Leeds, the communication strikes off to the north-west, and passes through Carlisle to Glasgow and Edinburgh, for Scotland, and to Portpatrick, where a submarine cable across St. Patrick's Channel is laid to Donaghadee, and touch is gained with Belfast and Dublin. These lines are already completed and in working order; but there is still in progress a system direct from London to Birmingham, leading on to Derby, where it will branch to Liverpool and Manchester, passing through Cottonopolis to a point where it will join the Leeds-Carlisle communication. The direct service from London to Bristol, Southampton, and Portsmouth will be secured by six wires running to Salisbury, where they will separate, four turning to the Bristol Channel and two to the Solent. A couple of wires from Newcastle to Sunderland, and two more from the same centre to Darlington and Stockton, will complete the scheme of the Department. Altogether, a total of 10,375 miles will be covered, and 2,829 tons of copper will be consumed, in the following proportions: 2,719 miles, at 800lb. of copper per mile per wire; 4,914, at 600lb.; 2,646, at 400lb.; and the submarine cable, 24 miles in length, which, being quadruple, gives a total of 96 miles. The mileage at present completed is 7,595 miles. The extent of private undertakings to be presently absorbed is about 28,000 miles. The distance to Dublin, as traversed by the wire, is 467 miles, which is a notable increase on the 334 miles followed by the railway from Euston *vid* Holyhead. The longest circuit over which the Post Office authorities have spoken by linking the largest possible number of wires is 1,270 miles, and the result of the experiment was quite satisfactory. It is expected that the new system will be open to the public in a few days. Wednesday's inaugural ceremony took place at the new building, known as the General Post Office North, when communication was first established with Edinburgh, then with Glasgow, Dublin, Belfast, and Nottingham. The voices were heard with the greatest distinctness over the longest distances, and one gentleman in Edinburgh subsequently amused the company by singing "Auld Lang Syne" and giving a whistling recitation.

THE CONTINUOUS-CURRENT DYNAMOS OF MM. F. BALAS AND L. COUFFINHAL.*

BY P. GIRAULT.

For a long time—say, from the date of the first really industrial applications of electricity to lighting—engineers have been anxious to reduce to a minimum the uncertainty arising from the responsibility left to the staff in charge of the machinery.

From a mechanical point of view, we have been led to use completely automatic lubricating apparatus. In steam-engines, the extension of electric lighting has been the cause of the continued progress achieved in the construction of governors.

The method which suggests itself at first sight of maintaining constant the pressure or voltage of a distributing system consists in connecting to a dynamo a special apparatus which, being affected by the variation of the voltage, produces automatically the desired regulation.

For distribution at a constant potential, the theoretical apparatus would comprise a very sensitive relay acted on by the variations of potential at the terminals of the machine or at the centre of distribution, working by means of a motor the handle of the exciting rheostat; the relay might be a voltmeter furnished with contacts which change the direction of the current in the armature or the field of the motor, accordingly as the voltage increases or decreases. These apparatus, fulfilling a part analogous to that of the Denis compensator in steam-engines, are perfect in principle. The great practical difficulty is to obtain at the same time sensitiveness, a sufficiently great speed, and a damping gear, so that the regulator does not sensibly overrun the correct position.

The principle of the pressure regulator of the Thomson-Houston dynamo has been followed by a great number of continuous-current dynamo builders aiming at constant pressure. They employ, in fact, apparatus producing a variable position of the brushes. The results are not very satisfactory, for the collectors are subject to destructive sparking, which is the more prejudicial as these machines are generally required for the production of high-tension currents. It would be much more rational to vary the excitation, for example, by a resistance shunting the magnet coils when it is a series machine. The chief advantage in shifting the position of the brushes is an almost instantaneous regulating effect which can be obtained.

Self-Regulating Dynamos.

Consideration of the characteristic curves of dynamos showed the possibility of compound machines, furnishing a practically constant difference of potential at the terminals, whatever the load may be, if the speed is maintained constant; but only an average voltage is thus obtained, the variations of which can be considerably reduced in proportion as the reaction of the armature is reduced.

This reaction of the armature, necessitates also a shifting of the brushes increasing with the load, and has caused a number of numerous barren discussions. In 1890, Prof. S. P. Thompson, introducing the consideration of the cross-induction, supplied a hypothesis which has since been justified by results. Herr Fischer-Hinnen published in the *Elektrotechnische Zeitschrift* an interesting article, in which he showed how this transverse induction could be predetermined, and described the practical methods to be used to diminish or suppress it, and which can be divided into two categories: (1) those destroying the action of the current traversing the armature by opposing to it an equal opposite magnetising force—*i.e.*, compensating coils; (2) those presenting to the transverse induction a magnetic resistance, which considerably diminishes it—*i.e.*, by slitting the pole-pieces.

The use of compensating coils gives the more correct results, but somewhat complicates the construction. The practise of slitting the pole-pieces presents certain difficulties. M. Guilbert has described in *La Lumière Electrique* the method employed by M. Labour, engineer of the Société d'Eclairage Electrique. The pole-pieces are cut in two, and the two halves are united by cast-iron ribs, offering considerable magnetic resistance.

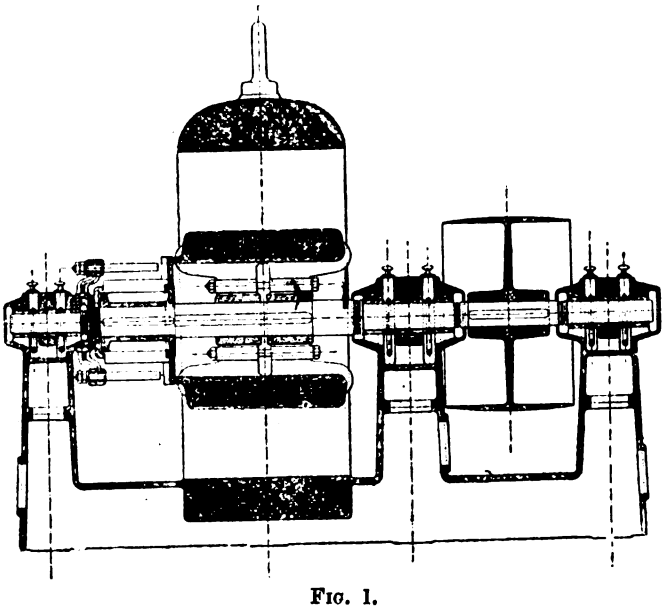

Fig. 1.

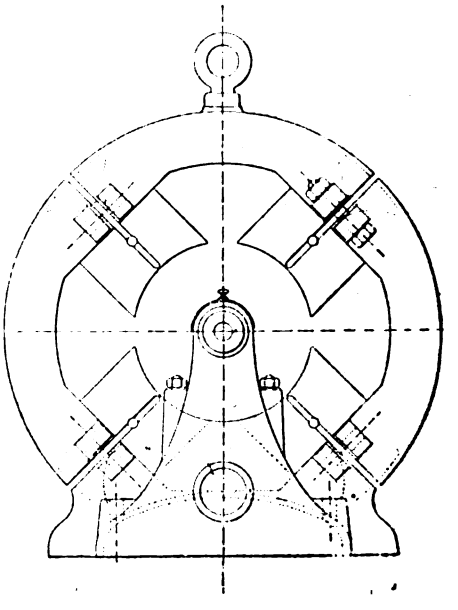

Fig. 2.

MM. F. Balas and L. Couffinhal, electrical engineers, of Chaléassière, Saint-Etienne, completely divide the body of the magnets by air-gaps passing through the axis which divides them into two equal parts; the two halves are separated by a non-magnetic metallic plate offering to the transverse fluxes an air-gap, as shown in Figs. 1 and 2.

A 55-kilowatt dynamo made by MM. Balas and Couffinal has been fixed in the electric central station at Saint-Etienne, and supplies on a full load a current of 500 amperes at 110 volts at 500 revolutions per minute. It is of the four-pole type. Figs. 1 and 2 show respectively the longitudinal sections of the armature and the field magnets of this dynamo. The foot of the bearing pedestal is a surface turned concentrically with the bore of the pole-pieces. Lubrication of the bearing is automatic, and of the Decoster ring system, the oil being circulated by eccentric rings hung on the shaft.

The armature is of the Gramme ring type, the core of which is composed of soft iron plates 0·0078 square inch thick. These plates are first coated with coal-tar oil to prevent rust, which often penetrates the insulating material. They are afterwards piled upon two bronze spiders, each plate being separated by a very thin sheet of paper. The two spiders are afterwards fixed on the shaft, upon which they are keyed and firmly pressed together by six steel bolts. These bolts are placed comparatively close to the shaft so that they neither obstruct the windings, nor are subject to Foucault currents.

* From *L'Industrie Electrique.*

Digitized by Google

The core thus formed is insulated along its periphery by means of two superposed cloths covered with bitumen, between which are placed thin sheets of mica; upon the lateral face and in the interior, insulation is obtained with vulcanised fibre. The plates of the collector are insulated by mica. The section of the iron of the ring—that is to say, that through which the whole of the flux emanating from one pole passes—is 76·725 square inches without the insulating material. The induction admitted is 12 kilogauss. The outside diameter of the core is 21·079in. It is wound with a conductor in 120 sections of two turns each, the conductor being formed of four parallel wires, each of 0·113in. diameter, insulated by two layers of cotton, then gum-lacquered.

The framework of this four-pole machine consists of four pieces of soft cast iron, the planes of intersection passing through the axis of the machine and dividing the pole-pieces into two equal parts. These four portions of the framework are supported one on the other only by the bronze block separating them, so that between the two contiguous pieces of cast iron forming a pole-piece there an empty space of two centimetres constituting a very strong resistance to the transverse fluxes. These four pieces are connected together by eight bronze bolts pressing upon ear-pieces fixed above the place reserved for the magnet coils. These bolts go through the bronze plates and the cast-iron ear-pieces. The lower segment of the magnet is cast with the foundation plate.

The induction in the cast-iron portions of the magnetic circuit is six kilogauss. This induction and that of the armature area are perhaps a trifle weak, and for this reason the dynamo is heavy, but the builders estimate that this weight is necessary for the machine.

The section of the cast-iron circuit is 206·15 square inches for the total flux emanating from one pole. Its length is 47·28in. The diameter of the boring of the pole-masses is 22·14in., which gives 1·064in. as the total length of the air-gap. The electric losses are 1,100 watts in the magnet and 2,100 watts in the armature. The cooling surfaces are—1·86 square inch per watt wasted in the magnet-coils, and 0·775 square inch per watt lost in the armature, counting only the surfaces which are well ventilated. The excitation required by the four magnet-coils in open circuit is 20,600 ampere-turns, which is obtained with a current of 9·2 amperes through 2,240 turns of wire of 0·121in. diameter insulated by a layer of cotton; at full load a supplementary excitation of 1,800 ampere-turns only is required on the four pole-pieces for compensating the reactions of the armature.

Although no extensive trials have yet been made with these machines, MM. Balas and Couffinhal believe that they can easily obtain a commercial efficiency of 92 per cent. What is more important is the absolutely safe running of these machines, the lag being absolutely nil whatever may be the load. This is a very appreciable quality in central stations of average size subject to quick variations of load.

THE QUALITIES OF MANGIN AND PARABOLIC MIRRORS.

With reference to the article on projector mirrors, which appeared in our issue of 17th ult., we have received the following communication from Herr F. Nerz, of the Elektricitäts-Gesellschaft vormals Schuckert und Co., of Nuremberg:

Experiments were made by the French Government in January last at Toulon, with the result that the parabolic mirrors of Messrs. Schuckert and Co., of Nuremburg, were found to be superior to the Mangin mirrors of Messrs. Sautter, Harlé, et Cie., of Paris. Trials by other States between 1889 and 1895 have without exception had the same results. That any Government, especially the French, would take the part of the German industry against a native industry is doubtful. The French Ministry of Marine, on the contrary, gave the greatest consideration to the home industry, and only this consideration can have determined the fact that, in spite of all experiments, the Mangin mirror is still used in the French navy. At Toulon and Ismid, Messrs. Sautter, Harlé, and Co. have returned the Mangin mirror in the possession of the arsenal as being unsuitable for purposes of comparison, and supplied new Mangin mirrors in new apparatus from Paris.

In order to weaken the results of the experiments, and to reverse the decision of the public, Messrs. Sautter, Harlé, and Co. have in the *Electrical Engineer* of 17th ult. a treatise which is so far from the technical calculations and the results of practice that it is advisable that a correction should be set before your readers.

In paragraph 1 of their pamphlet, Messrs. Sautter deal with the parallelism of the reflected rays, and grant that in the Mangin mirrors manufactured by them the focal length of the single zones deviates by 0·5 millimetre. Against this, the false assumption is made that in parabolic mirrors the focal points of the single zones also do not coincide, and that often there is a deviation of 1·5 millimetres. As a matter of fact, the deviation stated by Messrs. Sautter-Harlé does not exist in the parabolic mirrors which for a number of years have been made by Messrs. Schuckert. The silvered surface in these parabolic mirrors has such a focal length that all the original parallel incident rays are reflected up after reflection on this hinder surface from the front surface, so that they meet in the focal point of the front surface. Messrs. Sautter-Harlé would do well to state what sort of mirror is referred to, as their assumption does not exist in parabolic mirrors in practical use.

In paragraph 2, Messrs. Sautter-Harlé deal with the dispersion found in using an arc lamp with horizontal carbons. They forget therein that the projection of the crater disc on the surface of the mirror is bounded, not by a half moon, but by an ellipse. They further forget that for the dispersion, not only the small axis, but also the larger axis is to be taken into consideration. They also forget that by moving the focal point for a given part of the mirror surface, or by an alteration of the revolving surfaces according to determined laws—work which, contrary to the view of Messrs. Sautter-Harlé, could be more easily carried out with paraboloids than with the circular sections of the Mangin mirror—the beam is more intense towards the middle, and consequently weaker at the edge, and that therefore the field would be irregularly illuminated. The irregular lighting of the field has, however, hitherto been sharply found fault with, not only by Messrs. Sautter-Harlé, but also by Prof. Blondel. Further, Messrs. Sautter have hitherto brought forward as a special merit of the Mangin mirror the slight working arrangements, whereas now in the promised alteration of the surfaces of the Mangin mirror they arrive at complicated working parts, thus giving up their boasted advantage. Finally, prominence must be given to the fact that the arc lamp with horizontal carbons has hitherto been strongly combated by Messrs. Sautter-Harlé as being totally useless for projectors.

In paragraph 3 the firm refer to the angle of collection, but forget the practice adopted for years that the focal length is smaller in a parabolic mirror than in a Mangin mirror of the same diameter. Messrs. Sautter-Harlé's deductions from Figs. 4 and 5 are, therefore, not drawn for technical people who are versed in the manufacture of mirrors. The same holds good for the calculation of the intensity of the field lighted, as this is only correct for the central portion of the mirror, which generally receives no light. With the same angle of collection the Mangin mirror suffers at the thicker edge by absorption and decomposition of the rays, forming spectra. In central zones, also, there is trouble from absorption, and in a smaller degree by spherical aberration and decomposition, against which the parabolic mirror only suffers from dispersion.

In paragraph 4, the heating of the mirror by the arc is referred to. Messrs. Sautter-Harlé ignore that the Mangin mirror has globular surfaces and becomes thicker and thicker towards the edge, and that, further, the danger of breakage is greater than in a parabolic mirror, in which the thickness of the glass is uniform. When these points are examined, a parabolic mirror of 279mm. focal length is superior to a Mangin mirror of 318mm. A projector of

Digitized by Google

60c.m. diameter with horizontal lamp, however, reaches first its highest capacity with a collecting angle of 124deg., answering to a focal length of 250mm. This angle of collection is not obtainable in the case of the Mangin mirror.

In paragraph 5, Messrs. Sautter-Harlé discuss the homogeneity of the reflected beam. The theoretical calculations show here a superiority for the Mangin mirror when accurate mathematical surfaces are taken. But the theory suffers in practice through inaccurate grinding. The Mangin mirror has, I understand, been rejected by Switzerland, among other grounds, mainly on account of its low homogeneity, and the parabolic mirror has been selected. Besides, complete homogeneity is not at all desirable. What is much more required is to secure a strong light in the centre of the illuminated field, and to take something off of the borders. Then the observer can from his standpoint at some distance from the mirror most quickly and safely look up the desired object, and will not be dazzled by the outer rays of light. Notwithstanding these practical experiences, Messrs. Sautter-Harlé advocate an equal illumination, and give the operator the difficult task of looking for distant objects most possibly with the outer rays. The polishing method in the manufacture of parabolic mirrors at Messrs. Schuckert's works is so perfect that the illuminating power of the beam is graduated according to practical requirements. The concentration of the beam in the Mangin mirror, as well as in the parabolic mirror, is determined by the equation $D = d \cdot e \cdot f$. D is the diameter of the illuminated field; e the distance of the field from the mirror; d is the diameter of the crater; and f the focal length. From this is derived the long-known fact that, within certain bounds, by the approach of the crater the dispersion in both mirrors is increased without diminishing the homogeneity.

In paragraph 7, the coloration in the Mangin mirror is acknowledged, but an erroneous declaration is made by Messrs. Sautter-Harlé in connection with the coloration not being visible at greater distances. This is not due to the decomposed rays being united, but to their being absorbed by the atmosphere, as the penetrability is far less for coloured rays, especially green and blue, than for white rays. The coloration therefore is a loss which does not exist in connection with the parabolic mirror.

A further error is made (paragraph 8) in the calculation of the absorption in the Mangin mirror. This absorption is given in "Théorie des Projecteurs Electriques," by Blondel and J. Rey, chief engineer of Messrs. Sautter's firm, as 0·985 per cent. for glass of 1cm. thickness. We thus have, according to the Blondel formula, 5 per cent. loss for glass 5cm. thick, and not 3 per cent., as stated by Messrs. Sautter.

A great mistake is made by the firm in connection with the durability of the mirror. As in the case of an oil or gas lamp, a thin cylinder of equal thickness is more durable than a thick cylinder of unequal thickness, so the influence of heat is better withstood by a parabolic mirror than by the Mangin mirror, which increases in thickness towards the outside. This consideration is confirmed in practice. Among all the parabolic mirrors in use in the German army not one has received injury in use, though one was damaged by carelessness when not being used Out of 550 parabolic mirrors sent to different parts of the world, none has been damaged, save by carelessness. In one instance the whole projector was upset from a wagon, causing even iron parts to be broken, but the parabolic mirror remained uninjured. What experiences can Messrs. Sautter-Harlé give to compare with these?

In paragraph 10, Messrs. Sautter-Harlé express themselves on the manufacture of parabolic mirrors, but conceal the fact that they do not know the only proportional method of production in the world, which is carried out at the Schuckert works. This method of production is protected by many patents in all leading countries, but, in addition, many important details are kept secret. The difficulties of production, the inaccuracy of machinery, the faulty handicraft of the workmen, which Messrs. Sautter would doubtless meet with in the case of a new contrivance, have been overcome in the 10 years' working of Messrs. Schuckert. At the present time the workmen, when the machines have been put in, have only to bring up lubricating oil and polishing material and attend to the forward and reverse movements. This work may last longer and be more difficult in the case of parabolic mirrors than in that of Mangin mirrors. This is, however, all the same to buyers as long as the product of the work, the parabolic mirror, is essentially better and not dearer to any appreciable extent than the Mangin mirror. What the Mangin mirror saves in labour is counterbalanced by dearer material. The differences given by Messrs. Sautter-Harlé in the focal length of the different zones, as well as the calculated angle of dispersion, do not occur in the Schuckert parabolic mirror. I therefore can find no other explanation than that either Messrs. Sautter-Harlé have themselves tried to produce a parabolic mirror, or that they are directing their attack against the competition which has arisen with them in France.

The figures relating to the parabolic mirrors of Messrs. Schuckert have been published by me in No. 27 of the *Elektrotechnische Zeitschrift*, 1894, together with a table. It was there shown that the dispersion of a mirror of 600mm. diameter, and 250mm. focal length, at 60 amperes and 12·1mm. crater diameter is 2° 47′, and not 2° 20′. The values given in my table are guaranteed in all Messrs. Schuckert's deliveries, and as far back in 1890 for all the projectors for the Belgian forts on the Maas.

The experiments of Herr Tschikoleff in connection with the Russian artillery show the severity of his method, while the extent of the error is now recognisable from the reflected-line system. On the grounds of these experiments, Tschikoleff gives in No. 13 of *L'Eclairage Electrique*, 1894, the following testimony: "Since 1889 there have been commenced to be installed in the forts parabolic projectors in glass by Schuckert and Co., of 94cm., the advantages of which, compared with those of Colonel Mangin, were established by very careful experiments at the Cannon Works and at the Grand Polygone de l'Artillerie . . . The most powerful electric projector which we possess is the Schuckert glass parabolic projector, about 940mm. in diameter." As regards this 940cm. mirror, 40cm. belong to the frame, so that really a 900mm. mirror should have been referred to.

In *L'Eclairage Electrique*, p. 54, photographic tests of projector mirrors were given (see *Electrical Engineer*, April 19 last), in which a photograph was wrongly attributed to a Schuckert mirror. Herr Tschikoleff wrote to that journal pointing out the mistake, his test referring to a mirror made by another firm, and he stated that he had never met with a Schuckert mirror so imperfect. I have in vain looked for the correction in *L'Eclairage Electrique*.

It will be obvious to your readers that the whole pamphlet of Messrs. Sautter, Harlé, and Co. is of a polemical character, which ignores the teachings of science and technical experience.—F. NERZ.

THE MECHANICAL PRINCIPLES OF ELECTRICAL ENGINEERING.*

(Concluded from page 664.)

In the instance previously referred to the hourly output of the destructor amounts to 300 horse-power hours, or 300×24 horse-power hours per diem, or $\frac{300 \times 24}{8}$ horse-power hours per hour during eight hours. If this can be done, then 900 h.p. would be available to meet the maximum demand of 550 h.p. for electric lighting required in an initial installation. Although this may be taken as an instance in which the demand for power is intermittent, the generation of electricity for lighting is by no means the only case in which power storage would prove invaluable. Unless some means can be found for storing the energy in some form or another, the greatest constant duty that could be imposed on the destructor would be equivalent only to the minimum energy that the furnaces furnish. It would be another matter if some fresh and unexpected demand for power were to crop up, such that its magnitude varied

* An address delivered to the students at the Croydon County Polytechnic by Mr. H. B. Ransom, A.M.I.C.E.

Digitized by Google

coincidently with the heat derived from the refuse, but such a demand is almost inconceivable. It has been proposed to utilise it for sludge-pressing or pumping sewage; but neither of these suggestions recommend themselves as suitable duties for refuse furnaces unaided by any storage scheme, owing to the unfortunate coincidence that both the sludge to be pressed and the sewage to be pumped have to be dealt with as delivered, and the maximum delivery corresponds precisely with the minimum generation of heat from the refuse, saturated as it is at such periods by the heavy rainfall.

Several modes have been suggested for the storage of energy continuously generated by destructors. It has been proposed to establish large high-level reservoirs into which water might be pumped. Prof. Forbes brought this scheme into great prominence when discussing the available means for lighting Edinburgh. In this instance, Arthur's Seat was proposed as the site for the water storage, and the falling water was to drive turbines. Presumably, this scheme was too expensive, for little has been heard of it for some years, and the city already possesses its own lighting scheme. The same objection applies to the adoption of electric storage, for although batteries can now be made to work at a high efficiency, their cost usually precludes their use on any very large scale. The third method of storing the spare energy of the destructor owes its origination to Mr. Druitt Halpin, M.I.C.E. It is assumed that sufficient boilers will be placed in connection with the furnaces to reduce the temperature of the escaping gases to about 500deg. F. before reaching the chimney. These will be constantly generating steam at a pressure about 100lb. per square inch higher than that used in the engines. This steam will be passed into a sufficient number of cylindrical receivers or reservoirs nearly filled with water, which will be gradually raised in temperature and to the pressure of that of the incoming steam. Assume that this water be raised to 250lb. pressure during the 16 hours when electric light is but little required, and assume that the engines are at work at 150lb. pressure. Then during the eight hours' heavy load the engines will be able to use the steam that is then being generated by the destructor, and, in addition, steam may also be drawn from the reservoirs by merely relaxing their pressure. We do not propose to go fully into Mr. Halpin's

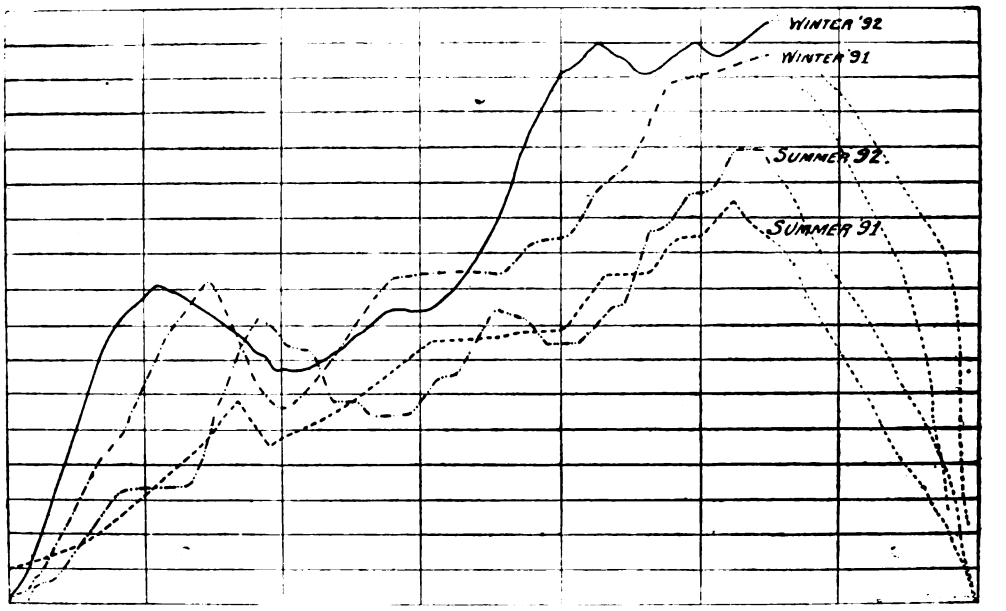
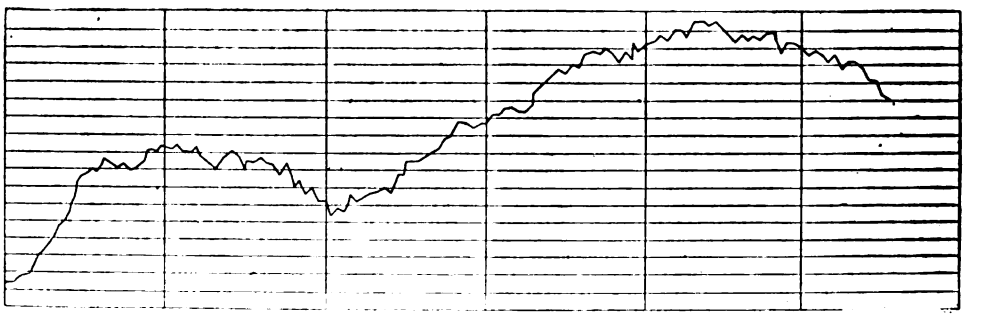
"thermal storage," but it will not be out of place to indicate a very important advantage which this method of dealing with the question entails. It clearly becomes only a question of pipe-work arrangement to secure all deposit from hard water taking place in the reservoirs instead of in the boilers. Incrustation in the reservoirs becomes in this instance an advantage as a non-conductor, instead of the dangerous and costly evil it would be did it occur in the boiler. Although this scheme has not yet been put to the test of actual practice, there appears to be little doubt that it will be applied before long, and, according to the opinion of many experts who have examined it with considerable care, with every prospect of success. Its practicability is also to some extent confirmed by the successful working of a system of transmission of power by hot water now in use in Boston, U.S.A. In this instance, according to Mr. T. L. Miller, A.M.I.C.E., in a presidential address to the Liverpool Polytechnic Society, a 4in. supply pipe has been laid round a district, with an 8in. return to the boilers. The water is heated to about 400deg. F., and for power purposes it is allowed to flash into steam at 70lb. pressure. It is further stated that as the pipes are well covered, the loss by radiation in the coldest weather is only 3 per cent.

It might, perhaps, be thought that another mode of storing energy might be found by merely allowing the refuse to collect, and burning when required. This, however, is not only highly objectionable on hygienic grounds, which alone ought to be sufficient to condemn it, but we also very much doubt whether it would be practicable. Very large storage area would be required, the labour of handling would be nearly doubled, the number of cells trebled, and the furnaces would be cold, comparatively, when first started, and require reheating every time they were used. Thus it might be expected that working expenses would increase and efficiency diminish. A capital illustration of the influence of the thermic capacity of the massive brickwork structure usually composing the cells is provided by the weekly chart showing temperatures of gases escaping from one cell. The particular cells are comparatively old-fashioned, and therefore the temperatures cannot be taken as indicative of possible results with modern appliances. On Monday morning, when the fires are restarted after having been banked up on Sunday, the temperature in each flue is but little over 700deg. F. A gradual rise goes on during the week until a maximum of 2,200deg. F. is reached on Friday, and then, probably owing to the delivery of a poorer quality of refuse, there is a slight fall until closing time on Saturday. The slight but well defined fall in temperature on Tuesday afternoon and night is due to the vegetable collection after a market day. Another experiment confirms these conclusions, and is also illustrative of the different calorific values of summer and winter refuse. The temperatures were in this instance taken in the main flue of the same destructor as the previous one.



Weekly Chart, showing Temperatures in Main Flue.

Although certain schemes that have recently been suggested for screening and burning do not come strictly under the heading of destructors, yet some experiments that have been made in this direction are instructive, inasmuch as they afford us the means of obtaining the calorific value of dried and screened refuse. According to Messrs. Rawson and Smithson, who tried three tons of Ravensthorpe refuse in this way, 1lb. of the dried combustible portion evaporated 3·23lb. of water (gross) when burned under a Lancashire boiler. This figure, of course, does not represent the available or net steam that could be applied to external motive-power purposes, but it affords us an idea of what the calorific value of the dry combustible portion really is. Thus, in some earlier calculations we assumed that the dry combustible portion was as good as coal, but apparently Ravensthorpe dry combustible refuse is only about one-third as good. Substituting this calorific value for the one we previously took (=coal) we see that 1lb. of unprepared refuse containing 25 per cent. moisture, 25 per cent. incombustible will only evaporate ¼lb. water. This is, of course, a very low evaporative value, and we can only assume



Weekly Chart, showing Temperature of Gases Escaping from One Cell. Each Vertical Division represents 100deg. Fahr.

Digitized by Google

that the experiments of Messrs. Rawson and Smithson were exceptional, for very much better results have been obtained elsewhere in actual practice. Had schemes of this nature been suggested 25 years ago we should have expected a future for them, seeing that in those days not only were there no true destructors, but there was far less difficulty in getting rid of the portions that were screened from the refuse prior to burning for manurial purposes, and, also, the public were not then so sensitive as to smells and dust.

It may have been noticed that throughout but few figures have been referred to. These have been avoided for several reasons. Firstly, because the avowed objects have been only the consideration of the principles apparently underlying the destruction of refuse, and of the great difficulties attending the acquisition of complete and accurate information concerning the working of destructors; secondly, the figures which are of greatest interest—namely, those which enable us to arrive at the maximum temperatures and power attainable—have never, so far as we are aware, been experimentally determined, with adequate appliances, continuously over any resonable period; thirdly, the average results, which have recently been quoted so freely in nearly every technical journal of the day, impart no new information to genuine students of the problem, being actually but a repetition of the facts with which they have been acquainted for years past; lastly, these figures, such as they are, cannot be comparable, and tell us nothing, since in no cases do they represent anything more than some unknown fraction of the possible limits of power accessible, and under conditions which are completely at variance one with another. Truly, to quote the apt expressions of a recent speaker on the subject, our knowledge of these matters is in a chaotic state.

If, as appears conceivable, the combustion of refuse becomes in the near future the source of a vast store of a hitherto undreamt of energy, it is almost impossible to see to what climax it will lead. The husbandry of the masses may eventually turn out to be extravagance, and the wastefulness of the wealthy economy to the commonwealth—a possible parodox if it be found that the lingering embers of the domestic hearth can be more efficiently utilised by combustion in a destructor for generating cheap electricity to the relief of local taxation. These suggestions may also provide food for reflection to those who create the refuse, for they will have seen how their personal habits or occupation, their extravagance or their economy, their wealth or poverty are all strikingly reflected in the contents of the despised dustbin.

I have described first how mechanical engineers rely upon the experiments made in laboratories in order that their machines may be properly proportioned; next, how they rely upon the physicist to furnish them with information concerning thermo-dynamics in order that he may deal with heat-engines, and on the mathematician that he may estimate the extent and limits of the forces which he is directing. I have, lastly, given some interesting examples of the value of electrical knowledge in engineering research work. But the converse of each of these propositions is also true; for the physicist, mathematician, laboratory man, each and all in turn, avails himself of the experience and knowledge of the engineer to deal with the difficulties of his own case. *A priori*, this analogy by itself would be sufficient to lead one to believe that the electrician would also profit by such an association, and, as a matter of fact, the relationship is even closer. The electric engine, to be successful, must be designed by a combination of the mechanical engineer and the electrician, just as the ordinary steam-engine requires the assistance of the physicist and engineer. How would the expert in thermo dynamics who knows nothing of the laws of mechanics or strength of materials deal with solid iron and steel? This problem has been long recognised, and deals with the training of mechanical engineers; but such is not the case with the electrical engineer. Until quite recently the student worked at electricity and a little pure mathematics, was dubbed engineer, and cast on the world. So great has been the failure of such men, that Lord Kelvin is reported once to have said, that if the mechanical engineer increased his knowledge 10 per cent. by learning the rudiments of electricity he would become at a bound the electrical engineer of the day. Although this may have been true at the time that he put the remark forward, it can, I hope, no longer be said of the younger generation; for in all the larger schools time is devoted in almost equal amounts to the two branches of engineering, and the combination only is recognised as of service to the client of the electrical engineer.

THE USES OF ACCUMULATORS.

The following is the discussion which took place on May 13 on Mr. Howell's paper read before the Northern Society of Electrical Engineers.

Mr. Edmunds (president) said he was sure that they had all listened with very great interest to Mr. Howell's paper. The question of storage batteries and their uses was one which had forced itself before the mind of every engineer who had had anything to do with electric light supply. The great trouble, he thought, was to find the perfect accumulator. They all understood the great difficulties in the way of direct supply, and the need of some reservoir of electricity. Mr. Howell had read his paper clearly and well. He had not told them in what dark vault he had found his mystic scroll, but whatever cunning scribe had written that leaden document it certainly gave a good history of what had happened in the past, and he thought it also contained something prophetic as to what might happen in the future.

Mr. Wordingham said he thought it was extremely difficult to discuss a paper which introduced a good deal of controversial matter without first going into it, and in consequence of that he could only make a very few remarks. Mr. Howell's paper was not only most humorously and interestingly written, but it bristled with what he (Mr. Wordingham) believed to be facts. He thought, looking at it broadly, that it would be very difficult to assail Mr. Howell's position. To his mind, there was no doubt that storage to a certain extent was essential to the economical working of a station. In that city they had put down a very large battery of 400 h.p. for 2½ hours. This they had put within a mile of the station for the double purpose of effecting the economy Mr. Howell had spoken of, and to save putting down more conductors. He hoped they would introduce considerable economy by the use of the accumulator. One thing always occurred in dealing with these secondary batteries—they were useful for a light load, and so useful at a full load, that the difficulty was to know when to charge them. He agreed with many of Mr. Howell's remarks, and thought he (Mr. Howell) had put the whole case most admirably.

Mr. Rider said that while he thoroughly agreed with Mr. Howell on most of the points raised, so far as they concerned the generating station, he could hardly at that stage enter into the reasons why a high-tension system could still be of service, because they must take into account the distribution as well as the generation. Not like most men who put down high-tension stations, he had such faith in accumulators that he put them down wherever he could find a use for them, such as for exciting the alternators, the alternator being at the time always dependent upon its exciter. He put in accumulators because he knew they could be trusted when wanted to take up the exciting current. His experience of cells was that the Crompton-Howell cells were very good; they had the fault, however, which, he thought, all cells had, that although one could take a very high discharge from them for a short time, they could not be discharged at a high rate; that, he thought, was a point which some makers would do well to look at in the future. If the cells were discharged at a high rate, they should be charged at a high rate. Although the makers would guarantee them, and enter into a contract for the maintenance of these cells, he thought they would find that when the cells were at their best they were in another way at their worst. These were the chief points he had to speak about.

Mr. Clirehugh said he was very much in the same position as the two previous speakers, especially Mr. Rider; the paper, he thought, deserved to be discussed very much more fully than he thought any of them would be prepared to do then, as it was absolutely impossible to take notes of any length and follow what was going on at the same time. Mr. Howell had alarmed them very much by using the Kennedy table of coal consumption, but he did not think he (Mr. Howell) meant it to represent the actual working of a central station; they would see, by referring to the two tables, that when he had consumed 13·2lb. of coal per unit he had reduced his engine to 20 per cent., therefore the difference of 13lb. of coal as against the six would, he thought, never be sustained in practice. As regarded the load-curves, they were excessively interesting and, he had no doubt, accurate in a very great many cases. As regarded the £7,000 spent on the battery, Mr. Howell had allowed 10 per cent. per annum depreciation, but the question was, how long would the battery last? It struck him that 10 per cent., although a reasonable rate of depreciation in one way, was not satisfactory in another, because at the end of 10 years had they got the battery or had they to put down another £7,000? Regarding electric railways, he would like to know which had adopted the accumulators.

Mr. Corlett said he did not think he had any interesting remarks to make on the subject. He could answer Mr. Clirehugh's last question—that one electric railway which had used batteries

Digitized by Google

extensively was the Douglas and Laxey Railway, Isle of Man; he believed they ran the whole of their week-end service by means of batteries.

Mr. Fawcus said it had given him great pleasure to listen to Mr. Howell's most able paper, although personally he could not agree with much that he had said. The saving of £13 a day in coal looked very nice on paper, but he was disposed to doubt its accuracy. Still, he was exceedingly glad that they were going to have the opportunity of discussing the paper. It was almost impossible for anyone of them that night who had merely listened to the paper without having any opportunity of studying the figures to discuss the matter properly. If they had time for reflection, perhaps some of them would be able to put Mr. Howell right. Mr. Howell might have given them some little information as to the actual results in pounds of coal consumed per unit in the most modern battery stations. If such a large saving could be effected by the use of accumulators, why was it they saw an alternate-current high-tension station beating the figures of all continuous-current stations?

Discussion, May 27.

Mr. Cowan said that at the last meeting he felt anxious to check Mr. Howell's claim of a saving of £13 per day in coal by using accumulators in the American station, of which diagrams were before them. Since then he had gone carefully into the matter, and could not see that such a saving, or anything like it, was possible with so small a battery. The only way in which economy could be realised by the use of a battery was by storing electrical energy when it cost little to generate, and taking it out for the circuits when its generation first hand would be expensive. It therefore followed that the only saving which could be effected must be made upon the electrical energy which passed through the battery. How was a saving of £13 per day to be made by the use of a battery which only dealt with £5 or £6 worth of electricity, taking its fuel cost at 1d. per unit? He thought that under the conditions of load at the American station 1d. per unit for coal was an ample allowance. It might be claimed that a saving would be effected on the whole output of the station, as the load-factor of the engines was raised to 100 per cent., but a little consideration would show that that was a fallacy. The only further saving which could be made would be due to the better management of the plant on account of the reserve allowing of its better manipulation, but that was a small matter. It seemed to him that Mr. Howell obtained his result by comparing an actual diagram taken from practice with an ideal diagram where everything was done in a perfect way. If they looked carefully at the actual load diagram, they would see that it was peculiar in many respects. The "in-and-out running" of the engine load line suggested that the man who was jockeying that plant had heavily backed accumulators. Mr. Howell said that the engines were run as nearly at full load as was considered safe in American practice, but they ought to be run, not only at full load, but above full load. A steam dynamo which could not be run, at any rate for limited periods, 10 to 20 per cent. in excess of its full load—that is, load of maximum economy—was not fit for an electricity supply station. If, instead of spending £7,000 on a battery, they engaged the services of an engineer who understood better the principles of the economical management of an electricity supply station, they might effect an equal saving without the heavy charge to which a battery was subject.

Mr. Rider said he was very glad indeed that the paper dealt with the uses of accumulators alone, and did not deal with alternating and continuous currents. He believed that cells were a good thing to have in a station, for the reasons Mr. Howell had stated in his paper, for bringing up the engine load-factor to 100 per cent., and because the shifts could be reduced at a certain part of the day. He did not see that there was very much in the use of accumulators as a stand-by against breakdowns, because if the station was properly arranged he would as soon have a good engine and alternator to fall back upon as a set of cells. He thought that to attempt to deal with some towns and some districts with a low-tension direct station would, as the papers said, "take them all their time." Cells could be as readily used in an alternating-current station as in a direct-current station, and if the advantages were so great they could get them just as readily in an alternating station. Let the day-load alternator be fitted with a rectifier, and transform down to 150 volts or so much power as was not being used for the circuits. Send this transformed current through the rectifier and charge a set of cells. The engine load-factor could thus be brought to 100 per cent. throughout the day, and the cells could be used to run a motor-alternator whenever desired, and particularly after midnight and on Sundays. The whole steam plant could be shut down on those occasions. Although accumulators would enable them to do many good things, they would have to be very much improved before they would be highly satisfactory, because, as he remarked at the last meeting, cells could not be charged at a high rate, but it would take from eight to ten hours to fill them again; that was one of the points he thought the makers would have to alter before the cells would be of any great service.

Mr. Crompton said he was very glad to meet the society that evening. Mr. Edmunds had caught him, and he was very glad he had been caught, for two or three reasons. First, he believed he was addressing a meeting of young men all of whom were in charge of work or closely connected with electricity. He was sorry to say that in the old institution, which he had the honour to represent, they had far too much the case of a meeting consisting either of a number of students or teachers who had not yet had any practical experience of the business, and men who had all their own logs to roll. They sometimes got meetings that were not as practical as he would wish. He had read the discussions of the Northern Society, and they had appeared to him to be very much the sort of thing that he had often wished had been the case in his institution. He had read Mr. Howell's paper, and he thoroughly agreed with him in the remark he made on the subject, that the men above all others who they wished to hear speak were men in charge of the stations. He would rather not enter into much disputable matter, because, as they knew, he was said to be a strong partisan of the low tension and also it was known that he had business relations with Mr. Howell; therefore, he would rather let Mr. Howell fight his own battles, but he would like to state a few facts which he thought might prove useful to the society. It had been said that he was what was called a low-tension man; he was not a low-tension man at all, but he was most strongly an anti-alternator current man. Alternating currents were no doubt a splendid thing in their way to professors and schoolboys, but nasty things to deal with in central stations. One of the principal reasons why they were so nasty to deal with, was that they did not allow accumulators to be easily used. Mr. Howell had converted him to the use of accumulators, and the way he did it was to show him (Mr. Crompton) that he would be able to work without that anxiety and worry which attended all central-station work. Mr. Howell had said something about it in his paper, but perhaps he (Mr. Howell) had not dealt with it to its fullest extent. Mr. Howell had also mentioned in his paper about the wear and tear; that was perfectly true—the wear and tear of stations when there was a large number of different dodges for alternating arc lamps, etc.; then came a period which was no joke for the engineer in charge, and so far it had had the result of breeding a race of engineers of whom every Englishman might be proud. He had spent a lot of time travelling, seeing what other people did, and he had had the reverse thing played on him during the last few days. He had had one of the leading engineers from a big continental firm sent over to him to be shown round, and he had to be civil to him and tell him all he knew. The engineer had been examining him for eight days and he (Mr. Crompton) had been examining the engineer; between the two he thought it had proved a mutual benefit. This only showed what a lot they could learn from one another. It was perfectly true that accumulators did waste a certain amount of energy, but it was certainly not more than 15 per cent., and in some cases less. There was such a large saving by the better loading of the engines, and that was where the big saving took place. The difference between having engines loaded to about 50 per cent. and to about 90 per cent. was very large indeed. As regards the objections to Mr. Howell's arguments, very much the same words had been used four years ago as had been used that night; but he could only repeat that when they had tried the work would they believe how much easier, how much cheaper, and how much more satisfactory it was in every way. He had got an alternating station of his own at Chelmsford, and he had tried for two or three years to scheme in a few things to increase their income; one was the use of motors. He would only say that if any man would show him how he could drive four or five printing offices with motors without interfering with the lighting, he would make that gentleman a present of £50 to-morrow; and if they could show him how to use accumulators so that he could make money by them between his generating plant and his network, instead of between his network and the consumers, he would also be glad to hand over another cheque for £50.

Mr. Heaketh said he felt some difficulty in approaching a subject that had been so ably handled by the previous speaker, but he thought if he took it from another point of view he might perhaps be safe from being charged with using stock arguments. He had heard it claimed by advocates of batteries that the ideal use of electricity was that given to gas—that was to say, to store it up to be used just as it was wanted. He was aware that the argument was very far-fetched, and that it never was intended to accumulate all the supply, as in gasworks, but an analogy taken from this view might be instructive. Say they had an accumulator with a capacity of 14,000 ampere-hours. It would cost £7,000—that was to say, assuming 3½ watts per candle-power, they had for £7,000 a storage equal to 400,000 candle-power hours. For the same number of candle-power hours a gasholder cost £1,500. There was rather a wide difference between those two figures, and if they were to adopt very extensively any system of storage they must have something lower than the present capital cost of accumulators. He would like, if it was not asking too much, to have some typical cases given where the cost of coal could be given for the units that were taken out of the battery. As to the point mentioned by Mr. Cowan, of overloading plant, he would not like to be in charge of a station where they could not overload to at least 20 per cent., because if a portion of the plant broke down they must be able to overload at least that extent.

Mr. Clirehugh said he did not intend to say much that evening, as he had been away. They all of them, he thought, speaking for the society, considered it a very great honour that Mr. Crompton had come down that night to favour them with his views on the subject. He was not going to criticise the paper, but the point that occurred to him was this—the danger of a very able paper like the one before them falling into the hands of local authorities. It was a most extraordinary thing how the town clerks and such like people got hold of the wrong end of the stick. Speaking for the whole paper, he maintained that Mr. Howell had simply taken into consideration the fact that the people were going to fetch their electricity, but they must remember those were not the circumstances. They had got to supply electricity to the place where it was paid for. If Mr. Howell could show them the means of getting the electricity there, and still maintain the saving of £13 a day in coal, it was no doubt a really good thing.

Digitized by Google

Mr. Fawcus said that after the very strong condemnation of the use of the alternate current by Mr. Crompton, he felt some reply ought to be made. Although he was not a rabid supporter of any particular system, he desired to see the two fairly compared. He had taken out roughly the results obtained by the six commercially best low-tension stations, and the six commercially best high-tension stations as given in published returns, and the low-tension stations had the advantage in cost of production at present. It so happened that three of each kind were managed by corporations and three by companies. The six low-tension were Burnley, Brighton, St. James, Westminster, and Liverpool, and the six high-tension stations Newcastle, Newcastle and District, Hanley, Leeds, Huddersfield, and Portsmouth. The cost of production in the low-tension stations was 1·78d. per unit and in the high-tension stations 1·93d., being a saving in favour of low-tension stations of 7 per cent. in cost of production only; but that cost of production only meant about half the total cost of the current, so that the saving fell down to 3½ per cent. on the total cost. Again, the low-tension stations paid £120 per kilowatt for their plant, while the high-tension stations paid £80—that was to say, the low-tension stations, to obtain the saving, paid 50 per cent. more for their plant than the high-tension; also this comparison was very favourable towards the low-tension stations for another reason—the average time of running was four years, while the average time the high-tension station had been run was two years. Again, the districts that were being served in the case of the low tension were all congested districts, whilst in the other cases the districts were very much more spread about. He had remarked upon the peculiarity of the peak of the diagram shown of the American station, and suggested to Mr. Howell, that as the heaviest load came on at four o'clock in an afternoon in June, the station was probably in the neighbourhood of the south pole or the diagram was taken during an eclipse. Mr. Howell had, however, assured him this peculiarity was caused by motors running in at four in the afternoon. At all events it was a pity that a more reasonable diagram had not been chosen instead of one which appeared to show the station running under almost impossible conditions. He thought this was the most interesting paper the society had had, and it had provoked a good discussion. He was glad to have Mr. Crompton with them to hear his remarks.

Mr. Mountain said he had hoped to hear accumulators discussed. They were undoubtedly useful for many purposes, but they wanted to hear more as to their efficiency. He could not believe the saving shown by Mr. Howell would be realised. The figures given in the paper appeared very much like the figures representing the profits likely to be obtained according to the prospectus of some gold mining company; very satisfactory because the facts were so scarce it was impossible to check them, but he did not think the saving would be anything like that described, if any at all. He thought Mr. Crompton did not apparently appreciate the position of electric supply undertakings in provincial towns. The fact mentioned by Mr. Fawcus was of great importance in considering the relative values of each method of supply. The area of supply must come very largely into the question. Taking Huddersfield as an example, he stated that some houses taking a supply of electrical energy were as much as 3¾ miles from the supply station, and these houses were actually the best consumers, taking more energy than the largest buildings in the central portion of the town, owing to the fact they were burning their lights nearly all the night through, and he could not see how a provincial town was to be thoroughly covered with a network of low-tension mains, owing to the enormous amount of money required, although for congested districts they might do very well indeed.

Mr. Edmunds (president) said he thought Mr. Howell had given them a very good and interesting paper, and Mr. Howell had spoken very guardedly upon all debatable points. He congratulated him upon the modesty he had shown in not making references either to his own or to any particular accumulator, but had drawn the attention of the society as a whole to the valuable aid and help that central stations might receive through their employment. He noted Mr. Crompton's remarks about not mixing different kinds of current; that it was desirable to have one kind, and that direct, not alternating; but that it was not a question of limiting the direct to any particular pressure. Mr. Edmunds further remarked that all lamps ultimately took the same pressure (100 volts), so to speak, but the question as to what pressures should be employed or what kind of current, alternating or direct, between the station and the consumer, was one to be settled by local conditions, such as distance and quantity to be supplied. Mr. Mordey had once said to him that the beauty of an alternating current was that it would not charge an accumulator. He asked him if he were still of that opinion on seeing him one day after reading the paper. Mr. Mordey's reply was: "Show me a good accumulator: a really good one, and probably I shall alter my opinion." Mr. Edmunds thought it was a good accumulator that was wanted. If, instead of the loss now accruing owing to chemical changes, we had something more analogous to a gasholder or water reservoir, then there could be no doubt as to the advantages of the use of accumulators in connection with central stations. He also remarked that they could hardly expect to get the whole of the information regarding accumulators—their *pros* and *cons*.—from one gentleman who only represented one particular kind, and he regretted there were not others present to advocate and discuss the relative merits of other forms of secondary batteries. However, considering the lateness of the evening, he would not take up their time further.

Mr. Howell, replying, said he thanked them very much for the kind way in which they had received his paper, and for the critiques they had passed upon it. Dealing with this criticism, he would take first of all the remarks which Mr. Cowan had made, since they showed he had been at some pains to work out the load curves and the figures upon which the economies to be effected by the use of accumulators had been based. Mr. Cowan had, however, unfortunately fallen into serious error in considering that the saving in coal would only be effected on the number of units stored by the accumulators. On the contrary, the saving was made on every unit generated, since the efficiency of the station as a whole was raised. As a corroboration of the saving of the 13 tons mentioned in the paper, it was only necessary to refer to the Kennedy table, where the pounds of coal per unit for the day's output was 7·33, and for the period of maximum load, when the engines would be running at higher efficiency, 6·1, or almost the exact ratio given for the station mentioned in the paper—80 tons without accumulators, 67 with. Mr. Cowan would thus see that his apparent generosity in giving the coal required to charge the battery was entirely misplaced, and, paradoxical as it might seem to him, the station required less coal for a greater number of units generated, when fitted with accumulators, than it would need for a small number of units generated without accumulators. With regard to Mr. Rider's remarks on accumulators and their use in alternating-current stations, there could be no question that the engineer in charge was considerably relieved by having in his exciting circuit a reserve such as an accumulator would give, and extension would probably take place in the way that Mr. Rider had suggested; in fact, the scroll had more than hinted that shortly after accumulators had been employed in alternating-current stations they were used for driving motor-alternators for the period of light load, and the time over which this light load extended was greatly lengthened by increasing the size of the accumulators, so that they could be charged at the period of heavier load, so as to make the plant run at the higher efficiency. This process was carried on to such an extent that finally the alternating-current station became a low-pressure continuous-current motor alternating station, and, strange to say, with marked economy. Mr. Hesketh's demand for figures as to efficiency was somewhat amusing. What need of enquiring too closely into the efficiency of the batttry when, inefficient as it was, it effected a saving in a station using 80 tons of coal of £4,300 a year? Mr. Hesketh, however, might take it that the energy efficiency over 12 months' running would not be less than 85·6 if the batteries were properly worked, and this figure had been attained in actual practice at one of the Westminster stations under Prof. Kennedy's charge. Accumulators were frequently overcharged, and it was not the fault of the accumulator manufacturers that the efficiencies obtained were frequently so low. Mr. Fawcus had brought an interesting list of stations, which he had, however, omitted to name, comparing the results of low-tension and high-pressure alternating systems, but he had omitted to mention that the periods of service in some of these stations are entirely different. Portsmouth, which was one of the stations named, did not give a constant service, hence its figures were of no earthly value at all. Any station could generate current at period of maximum load and pay. It was the period of minimum load that made electric lighting in some cases difficult from a commercial standpoint, and it was this period of minimum load that accumulators took care of.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

DUBLIN TRAMWAYS.

SIR,—Mr. Owen acknowledges that he is in want of facts. This I suppose is the reason his first letter was so sadly deficient in that respect. If he had not suggested that he held a brief for the views and would-be requirements of all the various local authorities in this country, I should not take the trouble to test the value of his "certain knowledge." When I asked for Mr. Owen's identity, I did not do so, as he appears to think, for the purpose of passing the slightest reflection on his experience in the electric traction field; my object was to find out whether his championship of "Dickinson's system" was quite a disinterested one.

I thought I had clearly expressed in my letter that I did not desire to criticise the merits or demerits of any system, and I never gave it as my opinion that there was any loss of efficiency by the adoption of the South Staffordshire system. Not being a proprietor of patent medicines, I do not believe in one kind of pill curing every kind of malady, but think that each case would be more fairly dealt with in the hands of a competent diagnoser.

Mr. Owen in his letter of protest to you says that the adoption of the centre-pole system of lines already laid would, in his opinion, lead to many serious and fatal accidents. In the face of this prophetic utterance and my alleged ignorance of the system, how could I suggest it or anticipate on his part such a speedy retractation!—

Yours, etc.,
STEPHEN SELLON.

June 10, 1895.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 month
United Kingdom.....	3s. 3d.	6s. 6d.	13s. 0d
Other Places.....	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank.'*

BOUND VOLUMES.

Vol. XIV. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers or binding can be obtained, price 2s.

THE TELEPHONE SYSTEMS OF THE CONTINENT.

The publication of Mr. A. R. Bennett's book on this subject ought to do much to dispel the cloud of ignorance and mis-statement that has so long prevented our due appreciation of actual facts. The subject-matter of this book may well be divided into three parts—critical, administrative, and descriptive. The first of these only claims attention here; the others will form the subject-matter of a notice of the book. In his introduction Mr. Bennett is scathingly critical of the manner in which the telephonic business has been and is being conducted in this country. It is quite refreshing to come across a writer who fearlessly and relentlessly exposes the fallacious arguments that have so long held ground. Broadly speaking, our contention from the first as regards telephony has been that it is a species of telegraphy, and as such should be in the hands of the Government; that a telephone should be found in every ordinary house; and that the annual cost should be at the lowest possible rate. In England, however, we have the business run by a private company, or companies, with an inflated capital, inefficient service, high charges, and comparatively few customers. The value of a telephone to a subscriber increases more than in proportion to the number of co-subscribers. Telephony in this country was originally run for speculative and not industrial purposes, and all the energy and efforts of the past few years have failed to shake off the incubus hung round the neck of telephonic administration by the mistakes of the original organisers of the system. The point that Mr. Bennett drives home is that low rates attract subscribers, and will pay. He says that the advocates of low rates in this country have had their arguments met by a point-blank denial, and their opponents have asserted "that the low rates are not inclusive of all charges; that the subscribers have to pay the cost of their lines or instruments, or both, and after connection for any repairs that may be necessary; that foreign telephone companies are not burdened with such payments to the Government as are imposed on the National Telephone Company here," and a number of other excuses, which are fully set out, but which we need not recapitulate. Mr. Bennett has traversed the Continent to examine on the spot the facts of the case, and so far as his examination goes he says: "It will be found that no two nations have solved, or attempted to solve, the problem in exactly the same manner. In some cases the divergencies are wide, but in most, great intelligence, combined with solicitude for the public weal, has been brought to bear, often with the most satisfactory results." As regards that particular point—the rates—this is what our author says: "Full particulars are given of these variations (of rates) under the headings of the several countries, but it may be as well to state definitely here that inclusive rates, covering the supply and maintenance of all wires, instruments, and accessories, of £2. 10s., £2. 15s. 7d., and £3. 6s. 8d. exist in Norway; of £2. 15s. 7d. and £3. 6s. 8d. in Denmark; of £2. 9s. 7d. and £2. 17s. 10d. in Holland;

Digitized by Google

of £3. 4s. in Finland, and of £2. 16s. and £3. 12s. in Italy, while rates of £4 and £5 are of frequent occurrence elsewhere." A categoric denial is also given that low rates mean bad workmanship, and with regard to governmental or similar payments, it is stated "that many foreign companies are burdened with far more onerous payments to their governments or municipal authorities than is the National Telephone Company. In Madrid 20 per cent., in Bilbao 34 per cent., in Barcelona 33·75 per cent., and in Valencia 31·5 per cent. of the gross receipts are payable to the Government. In Italy, a uniform tax of 10 per cent. on the gross receipts and £2 per annum for every public telephone station (call office) is levied; in Russia, the tax is also 10 per cent. of the gross takings, while the Portuguese get off with 3 per cent."

These extracts, which are statements of facts, will once for all disprove the general statements and denials that have hitherto been so freely used, and the author states emphatically "that an exchange with metallic circuits, underground wires in the centre of the town to each block of buildings, and all modern improvements, could readily be made remunerative at £5 per annum, Post Office royalty included." The fact of it is that this introduction of Mr. Bennett consists of a mass of admirable fighting material, bearing upon its face the stamp of authenticity, and which not only the technical, but the general Press of this country should circulate as widely as possible. It is shown that official answers to parliamentary questions are woefully defective in accuracy, and it may be assumed that the truth of the matter has never before been placed before the public. The more these facts are considered, the more striking must be the conclusion that the cheapest, best, and most efficient form of telephone control is as a branch of the Government Telegraph Department. Then the work would be carried out systematically and not by piecework, so that as exchange was added to exchange and town to town, the benefit of cheap telephony would be more and more appreciated, to the advantage of the revenue.

THE CHELMSFORD ACCOUNTS.

We have received a copy of these accounts as presented to the Board of Trade. These accounts cannot be deemed very satisfactory, but it seems that the fault is in the charge made for public lighting being too low. The cost of electric energy delivered on to the mains is 2d. per unit, and the generation of 156,184 units so generated is £1,301. 10s. 8d. The selling price to private consumers is 6½d. per unit, and the net revenue derived from this source is £992. 6s. 8d. Now, the cost per unit is not the cost of generation, but this plus administration expenses, which bring the total cost to £1,953. 16s. 9d., or a cost per unit, say, of 3d. So far as the private lighting is concerned there is evidently a good profit, therefore a loss must come from the public lighting; for the total profit is only £210. 16s. 3d., a considerably less profit than is obtained from the private lighting alone. It seems to us that the public lighting, to be produced at cost price, ought to bring in about £1,500, instead of £969. 18s. 10d. Practically the accounts show a capital expenditure of £17,253. 16s. 6d., a revenue for the year of £2,164. 13s., with an expenditure of £1,953. 16s. 9d., leaving a profit of £210. 16s. 3d., with which to pay interest. The extension of private lighting will, no doubt, continue, and bring about a more favourable balance but we again say that in our opinion the public lighting is done at too low a figure.

COST OF PRIVATE LIGHTING.

The question of the cases in which it is advantageous for a consumer to lay down plant to generate his own electricity is a most interesting subject. A test of a private plant at Newcastle-on-Tyne by Mr. T. Hanning appears in another column, and is of great interest as an addition to the facts about private electric lighting plants. We are not sure whether the engineer making the test or the contractor made the deductions as to the annual cost, but we must protest against the use of figures obtained from special trials being used without extra allowances in the estimates as to annual cost. The results thus obtained, combined with the low labour charges and no allowance for repairs item, do certainly give an unduly favourable result for this small plant. In spite of this, we do not doubt but that the users will find their annual cost come out considerably under what they would have to pay to the supply company for the same light.

CITY AND GUILDS EXAMINATIONS.

SIR,—Reverting to your published "Answers and Solutions" of the 1894 Preliminary Examination of the City and Guilds of London Institute (see *Electrical Engineer*, April 19, 1895, page 452, col. 2).

Query 4.—A lamp circuit is supplied at a pressure of 100 volts. There are 42 lamps all in "parallel," and the resistance of each lamp (when hot) is 150 ohms. How much current will the circuit take when all the lamps are on? *Answer.*—28 amperes.

I am at a loss to understand this, as by Ohm's law $C = \frac{E}{R}$ = amperage. Now, here the E is a minus quantity by one-third, showing that the amperage is above $\frac{66}{100}$, or 0·66. Now, the lamps are in "parallel"; but the working of the answer seems to be done by multiplying the volts by the lamps—*i.e.*,

100 volts
42 lamps

total 4,200 volts ÷ 150 ohms

(*one* lamp's resistance); and, of course, gives just 28. What?

Now, if all the 42 lamps were in "series," the total resistance of the lamps would be 6,300 ohms requiring 6,300 volts for 1 ampere of current, and such a current would maintain a 32-c.p. 105-volt Edison-Swan lamp.

Suppose you take an example of the above, and say 100 volts by 28 amperes gives 2,800 watts; 2,800 watts ÷ 746 give close upon 4 h.p. (or 3·+$\frac{592}{746}$ths. Now, allowing three watts per candle-power, we have 933 c.p., or 58 16 c.p. + 5 c.p. The answer shows an incomplete working according to actual practice, or the problem may be abstruse, and if so shows a certain futility of purpose.

Now, if we divide the resistance 150 ohms by 42, the number of lamps, we have $\frac{15·0}{4·2}$ = 30·24 ohms for each lamp; and if we multiply the 100 volts by the 30·24 ohms resistance we have 3,010·3 watts, showing 4 h.p. + 26 watts.

Digitized by Google

Therefore that is not the working out of the problem. But if we divide our 100 volts by the 30·24, or, say, 31 ohms resistance, we have $\frac{E}{R} = \frac{100}{31} = \div 100$ by $31{\cdot}0 = 3{\cdot}07$ of an ampere; and as a lamp of 150 ohms resistance requires 2·3 amperes for a 50-c.p. lamp at three watts per candle-power, we should be safe at 2·8 amperes of current, being only a 0·5 ampere for margin and for drop of potential at the further lamp on the circuit. Therefore the error may lie in 28 amperes instead of 2·8 amperes.—Yours, etc.,

June 3, 1895. JEAN MUNIER.

[We have thought it best to insert this letter rather than to answer it privately, because an explanation of the matter may help other students. Our correspondent is quite right to stick to Ohm's law; his failure is probably due to little tortuosities in mathematical working, causing sad errors.

One easy way is as follows:

$$C = \frac{E}{R};$$

that is

$$\text{amperes} = \frac{\text{volts}}{\text{ohms}}.$$

Now, the ohms in this case

$$= \frac{\text{resistance of one lamp}}{\text{number of lamps}} = \frac{150}{42},$$

so that we may write, instead of $C = \frac{E}{R}$, $C = \frac{E}{\frac{R}{n}}$,

which is the same as $C = \frac{E \times n}{R}$.

Putting the given figures in the formula as it thus stands, we get

$$C = \frac{100 \times 42}{150} = \frac{2 \times 14}{1} = 28.$$

The answer, therefore, is 28 amperes.—ED. *E. E.*]

ELECTRIC TRAMWAY.

SIR,—Having visited Guernsey to satisfy my curiosity to see an electric tramway system in work, you will be interested to know that I heard nothing but satisfaction expressed by drivers, conductors, riders, and others. The only complaint was that the car rails are in bad condition for want of a better foundation and through wear when previously traversed by steam-engines. The general opinion was that no person noticed the overhead wires now they had got accustomed to them, and they *do not* constitute an eyesore, considering the successful working of the line. The cars travel at very good speed when fully loaded inside and out, and I saw three cars coupled and loaded go along right merrily. The stopping and starting is without jerk. There is very little sound, and complete freedom from the objectionable smells of oil, steam, and smoke given off from steam-engines. Electric traction undoubtedly stands well for a good future.—Yours, etc.,

J. H. HEATHMAN.

P.S.—I must add that the cars are lighted by electric incandescent lamps in a most pleasant way.

THE FARADAY HOUSE STUDENTS' DINNER.

The students' dinner of the Electrical Standardising, Testing, and Training Institution was held at the Imperial Institute on the 6th inst. In the absence, through domestic affliction, of Lord Castletown of Upper Ossory, the chair was taken by Mr. Robert Hammond, and among his supporters were Sir Courtenay Boyle, Mr. H. Kimber, M.P., Earl Russell, Colonel Gouraud, Mr. C. E. Spagnoletti, and Judge Snagge. About 170 guests were entertained by the Board of Control of the above institution, and after an excellent dinner the following toasts were proposed and responded to: "The Queen," proposed by the Chairman. Colonel Gouraud, in an amusing speech, proposed "The Institution." He referred to the old school started, in 1882, on the same lines by Mr. Hammond, which was too soon in the field to receive the requisite support. At that date, Colonel Gouraud had promoted a company with a capital of £1,000,000, of which £200,000 was called up, with the idea of lending money to electrical companies, etc., deserving of support. As no such deserving company or individual was to be found during the first two years, they called a general meeting and returned the money. Still, such times were now passed, and the speaker wished every success to the young men passing through the training course at Faraday House. Mr. R. Hammond responded, and, after describing some of his early experiences in the profession, which he had to work with his own hand for want of skilled assistance, he referred to the present state of the industry, and to the genuine investment of capital now being made in the electrical works of the country. The toast of "The Visitors," proposed by Mr. Francis Ince, was responded to by Judge Snagge, who said that all the relations of this Empire, on which the sun never sets, vibrated over a network of wires, the meshes of which were narrowing every day. The Chairman proposed "Past and Present Students," Mr. H. S. Gladstone, a present student, responding. Sir Courtenay E. Boyle proposed "The Board of Control and Staff," and after referring to the labour of the Board of Trade in connection with electric enterprise, he said that the field of electric energy which lay before them was unlimited. Electricians had conquered the earth and to a great extent the ocean, but was there any reason why motion should be confined to the earth and the water? It was for the young people before him, enthusiastic, learned, and vigorous, to apply their talents and their industry to this great region as yet unexplored. Mr. Harrison, principal of the institution, responded.

THE ABSOLUTE MEASUREMENT OF ELECTRICAL RESISTANCE.*

BY PROF. J. V. JONES, M.A., B.SC., F.R.S.

§ 1. If we take a conductor—such as this piece of copper wire—and make it part of a conducting circuit in which an electric current is flowing, we find that the E.M.F. between its extremities is proportional to the strength of the current passing through it, so long as it remains in the same physical condition. If either the E.M.F. or the current strength varies, the other varies in like proportion. Their ratio is constant—*i.e.*, it has a value independent of them, and depending only on the dimensions of the conductor, the nature of the material of which it is made, the state of aggregation of its parts, and its temperature. This ratio is called the electrical resistance of the conductor, and so defined it corresponds to a real physical quantity—it is a physical property of the conductor.

§ 2. Probably no physical measurement can be made with greater accuracy than the comparison of electrical resistances. Such comparisons are daily made in many parts of the world; and it is clearly desirable, in order that the results obtained by one man may have meaning for others, that all should make their reckoning in terms of the same unit. Accordingly, the scientific world has given great attention to the definition of such a unit, and much international negotiation has taken place with a view of securing world-wide agreement on this point.

The most obvious method of procedure is to fix upon some convenient conductor as a standard, and to call its electrical resistance the unit of electrical resistance, other electrical resistances being then expressed as so many times, or such-and-such a fraction of the resistance of this standard conductor. The disadvantage of this method of defining the unit is that the resistance of such a standard may change from time to time through alterations of its physical condition. The most notable change is consequent on change of temperature. This may, however, be allowed for by defining the unit as the electrical resistance of the standard conductor when it is at a specified temperature. But the other changes of physical condition, changes in the state of aggregation of the parts of the conductor, effects of strain, alterations of molecular structure, etc., are more serious, because they are unknown, and we cannot in our definition provide against unknown possible changes. We run the risk, therefore, of having a varying unit, and the prime requisite of a unit is constancy. In England the Government has taken this risk, and committed itself—at least, for the

* Friday evening discourse delivered at the Royal Institution, May 24, 1895.

Digitized by Google

present—to this method of specifying the unit of electrical resistance.

The denomination of the standard of electrical resistance contained in the recent Order in Council regarding standards for electrical measurements is as follows: "A standard of electrical resistance denominated one ohm, being the resistance between the copper terminals of the instrument marked 'Board of Trade Ohm Standard, Verified 1894,' to the passage of an unvarying electrical current when the coil of insulated wire forming part of the aforesaid instrument, and connected to the aforesaid terminals, is in all parts at a temperature of 15° ·4 C." This is a plain adoption of an arbitrary standard. The resistance of a certain piece of wire wound into a coil is made the legal unit, and if this resistance varies our legal unit varies with it. It is true that, in constructing the standard, efforts have been made to ensure that its resistance shall be equal to 1,000 million times the absolute unit of which I shall presently speak, that the standard was in construction based upon the ohm; but there is no provision in the Order in Council for revision if the standard varies, nor, indeed, has the Government any means at its disposal of directly measuring its standard in absolute measure. I seem to be finding fault. That is not my intention. I am only advocating progress. The time is ripe for the adoption of the absolute unit, not merely nominally, but really, for the frank acceptance of the absolute unit itself as the ultimate legal standard.

§ 3. Now, what is an absolute unit? The following considerations affecting physical measurements generally will, I hope, serve to make this clear. In order to specify the magnitude of any physical quantity we bring it into relation with a standard magnitude of the same kind, called the unit, and say that it is so many times or such-and-such a fraction of this unit. Thus we speak of a length of 6cm., a mass of 50 grammes, a time of 20 seconds, an electric current of 10 amperes, an electrical resistance of 30 ohms, and so on. For the purpose of this specification, any convenient magnitude of the physical quantity to be measured may be taken as the unit. But science has to deal with many kinds of quantities, and when we consider the various units as constituting a system our arbitrary choice is limited by two conditions of prime importance:

(i.) The units must be chosen so as to simplify as far as may be the statement of the quantitative relations existing between various kinds of quantities. Physical science, in so far as it is quantitative—may we not say in so far as it is perfected?—tells us of relations of interdependence between many different kinds of quantities. Thus, in geometry we have such relations between lengths, areas, and volumes; in kinematics, relations between these mathematical quantities and times, velocities, and accelerations; in dynamics, between these mathematical and kinematical quantities and mass, momentum, force, work, and energy; in electrical and magnetic science, relations between the foregoing quantities and electrical and magnetic magnitudes; and so on. These relations of interdependence are expressed in equations; and it is of obvious advantage, both for ease of arithmetical calculation and clearness of thought, to rid these equations as far as possible of superfluous arithmetical constants. This may be done by a judicious selection of units, by making the units of the quantities that appear most complex in their relations of interdependence depend upon the units of the quantities that appear in their nature to be simplest. A unit of any quantity so defined with reference to the units of quantities apparently simpler, is called a derived unit with reference to the latter units as fundamental. Thus, the attraction of the earth on a mass of 1lb.—the weight of 1lb.—is an arbitrary unit of force. The force that acting on a mass of 1lb. increases its velocity by 1ft. per second every second, is a derived unit of force with reference to the units of length, time, and mass as fundamental. It is usually called the absolute unit of force in the pound-foot-second system; and by the very nature of its definition it gets rid of an arbitrary constant in the relation between force, mass, and acceleration. If the arbitrary unit of force mentioned above—the gravitation unit—is used instead of the absolute unit, our dynamical equations are uselessly complicated by the introduction of "g," the acceleration of gravity at the particular point of the earth's surface at which we happen to be, and at the particular time when our measurements happen to be made.

(ii.) The second condition of prime importance to a scientific system of units is that the units of all quantities should be invariable, unaffected by conditions of time and place, and independent of the properties of particular bodies—*i.e.*, they should be *absolute*. The word "absolute" is in philosophy opposed to "conditioned." When it is applied to a unit in science, the implication should be that the unit is the same at all times and in all places, and that it is unconditioned by the properties of any specified body or bodies—*i.e.*, that its magnitude is brought into relation with and depends upon only the most permanent phenomena of the universe.

The modern system of absolute units goes far to fulfil the first of our two requirement; it only very partially fulfils the second. When we speak of an absolute unit at present, we mean a unit the magnitude of which depends on nothing else than the units of length, time, and mass, and the properties of the ether. The latter may be regarded as universal enough, but the units of length, mass, and time are arbitrary standards. The metre depends on the properties of a particular bar, the gramme on the properties of a particular piece of platinum, the mean solar second on particular bodies of the solar system.

The time will doubtless come when we shall be able to take another step forward, when we shall be in a position to make the unit of mass a derived unit with reference to the units of length and time as fundamental through that universal uniformity of Nature—the law of gravitation—the units of length and time being based on some more permanent phenomena of the universe (the properties of the sodium molecule have, for instance, been suggested) than the length of a particular bar, the motion of the earth on which we live. But we cannot take this step forward yet. We do not know either the gravitation constant or the velocity of light with sufficient accuracy to enable us to define by means of them units precise enough to meet the needs of practical life. Yet the fact that if we knew these constants, we could make an important advance in the realisation of a system of absolute measurement, is an excellent reason why the masters of physical measurement should apply themselves to their precise determination.

The use of a derived unit of mass would have this, among other advantages, that it would rationatise the dimensions of the electric and magnetic units in length and time, and relegate the irrationality to the ether, to which I believe it properly belongs. We must, however, for the present be content with a less complete reference to the most permanent phenomena of the universe; and by absolute measurement to-night I mean measurement in terms of a unit derived with reference to the units of length, time, and mass as fundamental—*i.e.*, a unit conditioned only by these units, and the properties of the ether.

§ 4. There is such a unit of electrical resistance—a unit derived with reference to the units of length and time as fundamental—the magnitude of which is independent of the properties of any particular conductor, any particular coil of wire, and which is conditioned only by the units of length and time, and the properties of the ether. It may, indeed, at first sight seem astonishing that a quantity so different can be expressed in terms of a length and a time. Yet so it is. We can, in virtue of experiments made 63 years ago in this institution by Michael Faraday, measure the resistance of a conductor with the help of no other standardising instruments than a tape or measuring machine and a clock. An electrical resistance is always proportional to a certain velocity, and if the magnetic permeability of the ether be taken to be unity, the number expressing the electrical resistance will be the same as the number expressing that velocity. The unit of electrical resistance may then be taken to be the resistance corresponding to unit velocity—*i.e.*, on the C.G.S. system, a velocity of 1cm. per second—and any electrical resistance may be conveniently expressed in terms of this unit as so many centimetres per second. You will observe that I do not say electrical resistance *is* a velocity—that would be to neglect the unknown dimensions of the magnetic permeability of the ether. If the unit of length, the unit of time, and the properties of the ether remain constant, this unit of electrical resistance remains constant. It is unconditioned by the properties of any material, by position in space, or point of time, and so far deserves the name of the absolute unit of electrical resistance.

§ 5. How comes it that resistance can be so measured? The answer to this question is best found in a description of some one of the methods by which the measurement of an electrical resistance in terms of the absolute unit can be experimentally made. And I proceed, therefore, to a description of the method which may fairly be described as the simplest, and which, in my opinion, having regard to the magnificent possibilities of mechanical engineering operations in this country, is undoubtedly capable of being made the most accurate of all the methods that have been proposed since the British Association Committee more than 30 years ago propounded the theoretical definition of the absolute unit. The method is due to Lorenz, and Lord Rayleigh, at the conclusion of his masterly determinations of the value of the B.A. coils in absolute measure, expressed himself in regard to it as follows: "On the whole, I am of opinion that if it is desirable at the present time to construct apparatus on the most favourable scale so as to reach the highest attainable accuracy, the modification of Lorenz's method last described is the one that offers the best prospect of success." The paper from which I quote contained a comparison of the various methods of measuring resistance in absolute units, and an invitation to others to join in the work. It was the starting point of my own researches in the matter, which have extended over some years, and I gladly take the opportunity of thanking Lord Rayleigh for this source of inspiration.

§ 6. Faraday discovered that if a conductor is made to move in a magnetic field so as to cut across the flux of magnetic induc-

Digitized by Google

tion, the conductor becomes the seat of E.M.F., and that the E.M.F. so developed is proportional to the rate at which the induction flux is traversed. If, for instance, we take a metal disc and make it rotate about a horizontal axis n times a second, any radius of the disc cuts through the earth's induction flux unless the plane of the disc is in the magnetic meridian. There will therefore be E.M.F. between the centre and circumference of the disc. Further, since a radius traverses the whole area of the disc n times in a second, the rate at which the induction flux is being traversed by any radius is n I, where I is the total flux of induction through the disc area. But the E.M.F. is proportional to this rate; therefore we have (with a proper choice of the unit of E.M.F.)

$$E^1 = n\,I,$$

where E^1 is the E.M.F. between the centre and circumference.

But we may, instead of using the earth's field, obtain a magnetic field by means of an electric current. The disc may be made to spin in the magnetic field due to a current in a coil of wire placed so as to be coaxial with it, and so that its middle plane coincides with the plane of the disc. In this case the magnetic field is symmetrical with regard to the common axis, and we have once more

$$E^1 = I\,n,$$

where E^1 is the E.M.F. between the centre and circumference consequent on the rotation of the disc at the rate of n turns per second in the induction flux due to the current in the coil, I being the total amount of that flux which passes through the disc circumference.

§ 7. Now, the current strength in a given circuit is by definition proportional to the intensity of the magnetic field produced by it at any point, and hence the magnetic induction through the disc due to the current in the coil is proportional to the strength of that current. It follows that the magnetic induction through the disc is made up of two factors—viz., the current in the coil, and the magnetic induction that would pass through the disc if unit current passed through the coil. The latter factor is called the coefficient of mutual induction if the coil and disc circumference and its value depends only on their dimensions and relative positions, and the magnetic permeability of the medium in which they are placed. If the latter quantity is taken to be unity, the coefficient of mutual induction is expressible as a length, and it may be calculated from observations involving nothing else than measurement of the radius and breadth of the coil, and the radius of the disc. Let this coefficient of mutual induction be denoted by M, and the current in the coil by γ^1; then

$$I = M\,\gamma^1,$$

and finally

$$E^1 = n\,I = n\,M\,\gamma^1, \text{ or } \frac{E^1}{\gamma^1} = n\,M.$$

§ 8. We have, therefore, two ways of expressing the ratio of an E.M.F. to a current. By definition (Ohm's law) this ratio is given to us as electrical resistance, or

$$\frac{E}{\gamma} = R.$$

By the experiment of the disc and coil it is given to us as the product of their coefficient of mutual induction and the rate of rotation of the disc (number of turns per second). And if the ratio for the disc and coil is made the same as the ratio for the resistance (which it is possible in practice to arrange), we have

$$R = M\,n.$$

If the magnetic permeability of the medium be taken as unity, M is a length expressible as so many centimetres, and the number of turns per second is the reciprocal of the time of one revolution of the disc. Hence the resistance may be expressed as a velocity of M centimetres in the time of one revolution of the disc. This makes it clear that, with the assumption in regard to the permeability of the ether (or air) that we have made above, any electrical resistance is expressible as a velocity of so many centimetres per second.

§ 9. We can in practice make the ratio for disc and coil the same as the ratio for the resistance by first sending the same current through coil and resistance, and then varying the speed of the disc so as to make the E.M.F. between its centre and circumference equal to the E.M.F. between the resistance terminals. How can we test the equality of the two E.M.F.'s? If two equal E.M.F.'s act in opposite directions in the same circuit, the result is electrical equilibrium. We have, therefore, to proceed as follows. Place the two E.M.F.'s in the same circuit so as to act in opposite directions; then if they are the only E.M.F.'s in the circuit, there will be an electric current round the circuit due to their difference if they are unequal, and no electric current at all if they are equal. The presence or absence of a current may be tested by the inclusion of a galvanometer in the circuit.

In practice, it is not quite so simple as this, because it is impossible to make the two E.M.F.'s in question the only E.M.F.'s in the circuit. There will be others, and especially thermo-electric forces, always present. But this difficulty may be met thus: Reverse the two E.M.F.'s we are comparing; if the current in the circuit is not changed by this reversal of both, they must be equal—*i.e.*, if the reading of the galvanometer be the same, whether the balancing E.M.F.'s are in one direction or the other, these E.M.F.'s are equal. The reversal of both our E.M.F.'s may be readily effected in practice by simply reversing the direction of the current through the coil and resistance.

To measure our resistance in absolute measure, we have, then,

(i.) To make the coil, S S S (Fig. 1), and the resistance, X Y, parts of the same main circuit, B C F S S S P X Y Q C B, and to pass through this circuit an electric current. A commutator, C, is to be inserted in the circuit in order that the direction of the current may be changed at will.

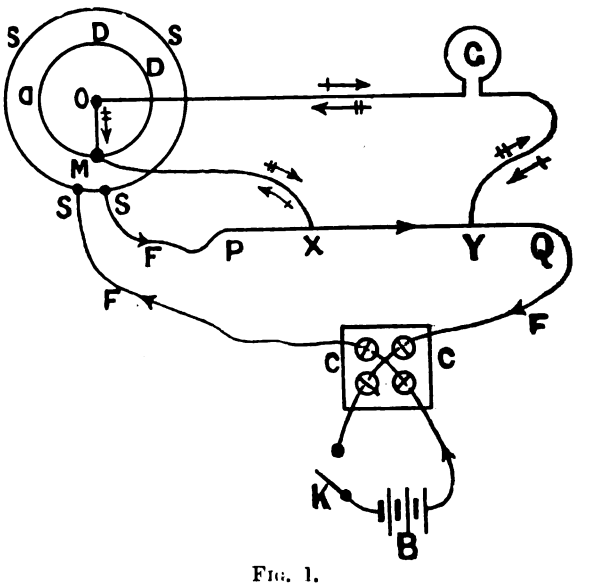

FIG. 1.

(ii.) To insert the E.M.F. between the centre and circumference of the disc, D D D, acting in one direction, and the E.M.F. between the extremities of the resistance acting in the opposite direction in a second circuit, X M O G Y X, containing a sufficiently sensitive galvanometer, G. Brush contacts must be made at O and M.

(iii.) To vary the rate of rotation of the disc until the reading of the galvanometer is the same, whether the current in the main circuit through coil and resistance is being sent by the commutator in one direction or the other.

(iv.) To measure this equilibrium rate of rotation.

(v.) To multiply this equilibrium rate of rotation (number of turns per second) by the coefficient of mutual induction of the coil and disc, which is calculated once for all from their measured dimensions. This product gives the resistance to be measured in absolute units.

[The necessary arrangements were here experimentally shown by the lecturer.]

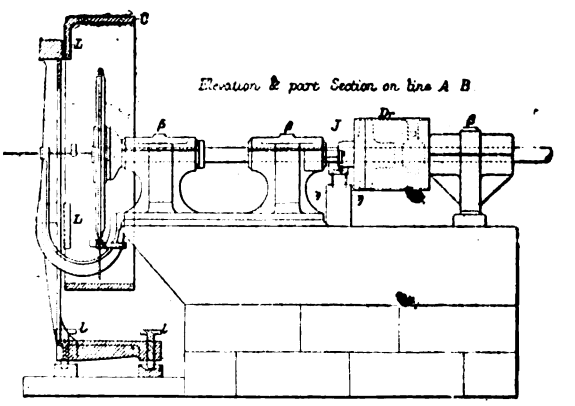

FIG. 2.

§ 10. I trust that I have said sufficient to make clear to you the general theory of the measurement of a resistance in absolute measure by this method. It now remains to consider very briefly the practical side of the matter—the difficulties that arise, the way in which they may be met, and the accuracy attainable. The time at my disposal does not allow me to do this at all completely, and I must content myself with touching on a few points of special importance and interest.

The first great desideratum is that we should have the rate of rotation of the disc well under control, that it should run as

Digitized by Google

uniformly as possible, and that its rate should be capable of sufficiently exact determination. The disc, axle, and bearings in my apparatus at Cardiff are of phosphor bronze, Figs. 2 and 3. The disc is insulated from the axle by well-paraffined ebonite, Fig. 4; otherwise there would be short-circuiting of part of its radius through the bearing and bed. It was at first intended to drive the disc by rope gearing from the electromotor. But in the course of preliminary experiments—though the rope was 40 yards long, and joining of the ends took place over a length of at least 6ft.—there was a sudden variation in speed, producing a distinct movement of my galvanometer needle, and visible at the tuning-fork, of which I shall presently speak, whenever the joint passed over the pulley. The rope gearing was therefore abandoned, and the motor coupled direct. The current driving the motor is supplied from secondary cells. It passes to the motor through resistance coils, and may be increased or diminished by throwing some of these coils into or out of the circuit. It may also be varied continuously through a small range by a slide

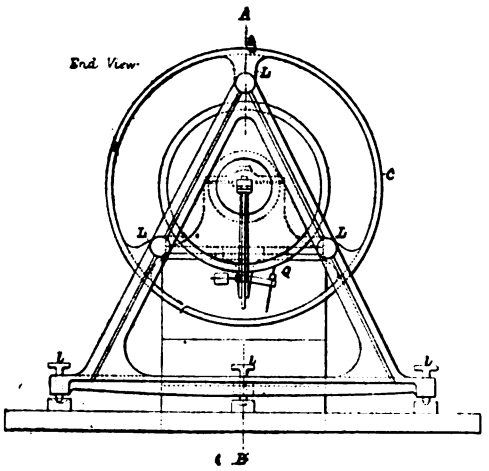

FIG. 3.

resistance of platinoid wire after the larger adjustment has been made. A shunt worked by a lever provides means of taking out or putting in a small resistance suddenly, so as to allow the observer controlling the speed while an observation is being taken, to counteract small variations of speed due to alteration n the lubrications of the bearings and the friction of the brushes

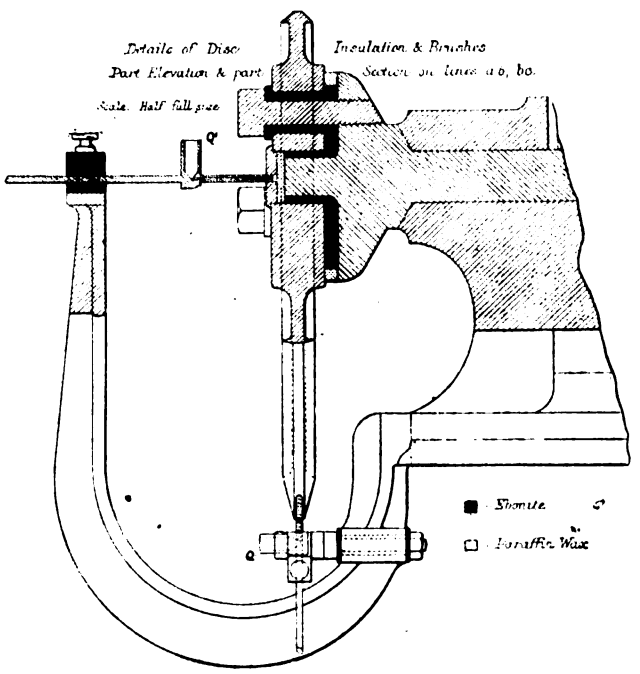

FIG. 4.

on the commutator of the motor. With these arrangements we can obtain any required rate of rotation from about 150 to 1,500 revolutions per minute.

It is of the greatest importance, if the observations presently to be described are to be made with ease, that the rate of rotation should remain constant for the four or five minutes required, and no effort made to compass such uniformity is thrown away. The design, workmanship, and lubrication of all the bearings require closest attention, and the friction between the brushes and the motor commutator should be reduced to a minimum. In my Cardiff apparatus the axle near the motor bears a heavy flywheel.

During a run the observer controlling the rate of rotation requires some test of uniformity, so that he may, if there is a quickening or slowing down, diminish or increase respectively the current through the electromotor so as to recover the initial speed. To accomplish this, it is convenient to refer the rate of rotation by a stroboscopic method to a suitable tuning-fork provided with riders and maintained in vibration electrically. Here is such a fork. At the end of each prong there is an aluminium plate with a slit in it parallel to the prong. When the fork is in equilibrium the slits are opposite one another, and an observer can see through both. When the fork is in vibration he can see through the slits only when they are opposite one another. This position occurs twice in every complete vibration. Hence, if the number of vibrations per second is, say, 64, he obtains 128 views per second.

Now, let us suppose that he looks through the vibrating slits at a drum or disc coloured black, on which a number of white spaces, which I will call teeth, are painted at equal angular intervals. Here is such a disc attached to the rotating axle, on which there are radial teeth. If the rate of rotation is such that in the interval between two views a tooth in any row exactly takes the place of the next, that row will appear stationary; if it does not quite do so, the row will appear to be moving backward; if it passes beyond, the row will appear to be moving forward. These phenomena I can show you by illuminating the rotating disc by intermittent light. The light of this alternating arc varies in intensity at each alternation, passing from maximum to maximum through a minimum that is, however, very far from darkness. Our speed is such as to make the 14 teeth appear almost stationary in this intermittent light. You can see the teeth, but they stand out somewhat faintly. The faintness is due to the fact that we have not complete darkness between the maxima of illumination.

(To be continued.)

TEST OF PRIVATE LIGHTING PLANT.

The following test of the private electric lighting plant at Olympia, Newcastle-on-Tyne, was taken by Mr. Thos. Hanning, A.M.I.C.E., for the directors of Olympia, Limited, on March 28, 29, and 30, 1895:

ENGINE.

Extracts from Engineer's Report.

"The combined plant tested during a five hours' run under varying loads gave very satisfactory results. The dynamo also did its work well, the pressure remaining particularly steady and fairly constant. There was no sparking at the brushes, and at the finish of the test there were no signs of overheating of any of the parts. The electrical efficiency of 92 per cent. places this machine in a good class. The combined efficiency of 69 per cent. is good for this system of generating."

The above plant consists of a 38-i.h.p. gas-engine and a 16-kilowatt dynamo, and was not fitted up with a view of making a show, but may be taken as a sample of our ordinary work.

It will be noted that there is a surplus of power in the engine over and above that required to drive the dynamo at full load, also that there is a difference in the efficiency of 4 per cent. between dynamo load and full load. If the engine was more nearly proportional to the work to be done by the dynamo, this 4 per cent. difference would go towards improving the efficiency of the combined plant, although we believe a surplus of power in a gas-engine to be a fault on the right side. This plant was supplied and installed by Rowland Barnett and Co., Limited, of Newcastle-on-Tyne.

LEGAL INTELLIGENCE.

SHELFER v. THE CITY OF LONDON ELECTRIC LIGHTING COMPANY—MEUX'S BREWERY COMPANY v. THE SAME.

In these two actions the Court of Appeal on December 18 last granted an injunction to restrain the defendant company from carrying on their works so as to occasion a nuisance to either of the plaintiffs. The plaintiff Shelfer is the tenant of a public-house, called the Waterman's Arms, at Bankside, Southwark, of which Meux's Brewery Company are the landlords The defendant company's works are in the immediate neighbourhood of the public-house. The nuisance complained of by the plaintiffs consisted mainly in vibration caused by the defendants' engines. The Court granted a suspension of the operation of the injunction for a period of six months to enable the defendants to decide whether they would appeal to the House of Lords. They decided to appeal, but subsequently they changed their manager, and they have appointed Mr. Frank Bailey, an experienced electrical engineer, to be their manager. Mr. Bailey has advised the defendants that it is possible to stop the vibration, and thus enable them to carry on their works without causing a nuisance. This being so, it would be useless to appeal and the defendants have withdrawn their appeal and definitely abandoned it. Mr. Bailey proposes to remove four vertical engines of the defendants, and to substitute four steam turbines, which, it is said, will produce no vibration. Some temporary mode of carrying on the works will be adopted while the alteration is being made.

Mr. Moulton, Q.C. (with whom were Mr. Renshaw, Q.C., and Mr. W. C. Braithwaite), for the defendants, applied on Wednesday for an extension of the period of suspension of the injunction until the Hilary sittings next year, to enable the defendants to make the proposed alterations. The turbines could not be obtained until next October. They are only manufactured by one firm.

Mr. Warmington, Q.C. (with whom were Mr. Badcock and Mr. Waggett), for the plaintiffs, opposed the application. He urged that the defendants had, by means of their appeal, obtained the benefit of a suspension of six months, and yet they had done nothing to abate the nuisance. It was impossible to rely on the evidence that the proposed alterations would be effectual, for Mr. Bailey, in his affidavit, did not even now admit the existence of any vibration.

The Court granted an extension of time till August 5 next.

Lord Justice Lindley said that the duty of the Court was plain. On the one hand, they were bound to see that private rights were not infringed; on the other hand, they were bound to protect even wrongdoers against oppression by what was known as "blackmailing." In the present case, his Lordship thought that some extension of time would be reasonable. He was not much impressed with what had been said about the turbines. But he thought there was reason to believe that the removal of the four vertical engines would diminish the vibration; and the evidence satisfied him that the defendants *bonâ fide* desired to abate the nuisance. The time would be extended to August 5 next, but the defendants must give an undertaking to be answerable in damages to the plaintiffs; and the defendants must pay the costs of the present application.

Lord Justice Lopes and **Lord Justice Rigby** concurred.

The application for an extension of time was made in the first instance to Mr. Justice Kekewich, by whom the actions were originally tried. He thought that as he had refused to grant an injunction which was afterwards granted on appeal, the application ought to be made to the Court of Appeal.

Their **Lordships** said that, notwithstanding the fact that the injunction, refused by the judge of first instance had been granted by the Court of Appeal, the application for an extension of time was properly made to the judge of first instance.—*The Times.*

COMPANIES' MEETINGS.

CONSOLIDATED TELEPHONE CONSTRUCTION COMPANY.

The fourteenth annual ordinary general meeting of the Consolidated Telephone Construction and Maintenance Company, Limited, was held last week at Winchester House, E.C., Mr. C. L. W. Fitzgerald occupying the chair.

The **Chairman**, in moving the adoption of the report and accounts, said the manufacturing profit during the past year was £1,403. The amount available for disposal was £2,866 from which it was proposed to pay a dividend of £1. 10s. per cent., leaving £1,236 to be carried forward. Competition had been exceedingly severe, and while the wages and expenditure remained practically the same, somehow or other at the end of the year the profit was always less. For the past three years the amounts had been £17,000, £15,000, and £13,000, and his personal view was that the Company was the victim of free trade, foreign competition, and high wages. It was now in contemplation to remove the offices from London into the country, where both labour and raw material were cheaper. In order to enlarge the scope of the Company's business arrangements had been concluded with the patentees of the capsule battery, by which the Company obtained the sole right to manufacture all supplies during the term of the patent—viz., 14 years. The chairman having reviewed in detail the history of the lawsuit in Belgium, said that the Company had been successful on appeal, and he hoped that when they next met he would be able to place a satisfactory statement before the shareholders.

Sir Alexander Armstrong seconded the motion.

Mr. Buck was of opinion that it would be a very risky thing for the Company to undertake the capsule battery business, and with regard to the removal of the factory, suggested that it would be more advisable to ask the landlord to reduce the rent than to incur the expense of migrating to the country.

After some further discussion the report was adopted unanimously.

At an extraordinary general meeting afterwards held, resolutions were passed increasing the powers of the Company and altering the title to the Consolidated Telephone Construction and Manufacturing Company, Limited.

HOBART (TASMANIA) ELECTRIC TRAMS.

The second general meeting of the Hobart Electric Tramway Company was held at the offices, College-hill-chambers, Cannon-street, on Tuesday, Dr. Alfred Mattei occupying the chair.

The **Chairman** stated that during the year they had carried 2,478,938 passengers, and had run 584,117 car miles, and their latest advices reported that for the month of April they had reduced their working cost to 6½d. per car mile. The Board were doing all in their power to reduce expenditure. The standing item of interest upon the first and second mortgage debentures could not, of course, be reduced. The line was being worked more cheaply than formerly, for there they were now doing the work themselves, instead of putting it out to contract, which was necessary in the first instance. Their revenue, taking everything into consideration, was satisfactory. Tasmania, in common with the rest of Australia, had gone through a great crisis, and they had suffered with the rest. Not only had people travelled less for necessity, but the pleasure traffic had also fallen off. It would be seen that they had increased their second mortgage bonds by £5,000, and these bonds now stood at £20,000, making, with the £30,000 of first mortgage bonds, a total of £50,000. With this £5,000 they had settled the liability of Messrs. Siemens Bros. and Co. of £3,400, and the vendors £500, leaving a small balance in hand. He believed that their next balance-sheet would compare favourably with the present one. They had not lost sight of their project of lighting Hobart by electricity, but he could not say more upon the subject at the moment. Their outlook was encouraging.

The report was adopted.

ELMORE'S GERMAN AND AUSTRO-HUNGARIAN METAL COMPANY, LIMITED.

The fourth annual meeting of the above Company was held on Wednesday at Winchester House, E.C., under the presidency of Mr. John MacFarlan, the chairman of the Company.

The **Chairman** said: Gentlemen, I do not think there is much in the balance-sheet that requires explanation; but if there should be anything not quite clear the auditors are here, and can reply to any question you may put with reference to the accounts. As we held the meeting last year in December, you are in possession of all information with regard to the position of the Company up to the end of the year, and I would only beg to draw your attention to the trading account in the metal balance-sheet, from which you will see that the loss on that account was practically nil. We think that, bearing in mind the difficult time we had during the year 1894, this result is satisfactory. As to the present position and progress of the Company, I am glad to inform you that from January 1 to June 8—that is, to Saturday last—the weight of goods sold amounts to 63½ tons, as against 22 tons for the same period last year, or, roughly, three times as much. This is a great advance, and one that should

Digitized by Google

continue and even increase with greater rapidity. An important point to be observed is that, although the price of copper has been low—in fact, the lowest on record—our prices have remained high, averaging £98 to £100 per ton. It has been a source of pleasure to the directors to find how the products of the Company have won their way into the esteem of consumers. This is exemplified by the fact that during the 23 weeks ended Saturday last we received 397 orders, as against 579 orders during the whole of last year, and that our customers have increased from 243 on December 31 last to 309 on the 8th inst. As to repeat orders, I will only say that we have received a large number—in some instances as many as 71 from one customer—a fact which I think fairly permits us to hope for much in the future. The duplicate order book is on the table, and I have no doubt you would like to inspect it, and see for yourselves the number of repeat orders we have received. We have this year introduced a new article made by the Elmore process which is likely to monopolise the market. This is a copper condenser cover for torpedo boats, and we have already supplied several to the Government contractors in Germany. We also continue to supply air chambers, corrugated tubes, and other articles of an irregular shape. The new plant is giving great satisfaction, and upon it being found successful we at once spent a considerable sum of money in altering and improving the old plant, and we are pleased to state that this is now as complete as that erected last year. It has taken a certain amount of time to complete the alterations, but the increase of production and the saving in the cost thereof will repay both the time and the money expended upon it. Notwithstanding this, however, we anticipate before the end of the year that the capacity of the present plant will be taxed to the utmost, and therefore we have to bear in mind the question of increasing it. You will, perhaps, remember that we can add a large number of tanks without additional buildings. As a matter of fact, we can add no less than 61 large tanks in our present building, capable of producing a further 15 tons a week, and you will readily understand that while the capacity of the factory would be increased to this large extent, the cost of production would be considerably less in proportion, as the standing charges would be about the same. The amount of profit would, therefore, be greatly increased. It is not proposed to put down the whole of the new plant at once, but only as and when the amount of work in view justifies it. We hope to be able to put down a further 16 tanks—equalling four tons a week—before the end of the present year, and as we have found the great value of the draw bench, we are also desirous of further augmenting this department by putting down a drawbench very much larger than those we have at present, in order to enable us to draw much larger diameter tubes than is now in our power. In conclusion, I would only state that your directors are satisfied that the shareholders are the owners of a concern that is likely to prove a valuable property. Of course, we have had our troubles—indeed, I should like to know the concern that has not; but we have worked hard to overcome those troubles, and I can only say that we are now commencing to be repaid. I want you to remember that the accounts before you are for the year 1894, and although the issue of the preference shares was a success, that year was not so productive as it would otherwise have been, owing to the new plant not being finished, and therefore it is no criterion of what can be done this year. There is one point, perhaps, I should mention and that is that we have been approached in two or three different directions by capitalists offering to find large sums of money for filling the factory with plant, and for the purposes of the Company generally. Our reply has been that the shareholders have had to wait a long time for a return upon their capital, and the directors do not see their way to enter into any scheme whereby the shareholders would lose any portion of the profits which are likely to come to them. I now beg to move the adoption of the report and accounts.

Mr. John Heal seconded the motion, which was adopted after some discussion, complaints being made by **Mr. Peters** and **Mr. Gladstone.**

The retiring director (the chairman) was re elected, on the motion of **Mr. Heal**, seconded by **Mr. Peters**, and the auditors (Messrs. Cooper Bros. and Co.) were reappointed.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Clevedon (Somerset).—Tenders are invited for the public lighting of their district every night in the year from sunset till midnight, for the Urban District Council. Tenders to be for one, two, or three years, and to be sent to Mr. Hy. C. Fry, clerk, Clevedon, by July 1.

Braila.—Tenders are invited by the municipal authorities of Braila, Roumania, by June 17 (29), for lighting the town by gas and electricity. Security required, 25,000f.—Tenders are also invited by June 17 (29) for the construction and working of electric tramways in Braila. Provisional security, 10,000f.

Cardiff.—Tenders are wanted for the supply of steam coal for the electric lighting station for half-year ending December 31, for the Corporation. Specification may be seen, and forms of tender obtained, on application at the office of Mr. W. Harpur, M.I.C E., borough engineer. Sealed tenders, endorsed "Coal for Electric Lighting Station," to be delivered at the office of Mr. J. L. Wheatley, town clerk, Town Hall, Cardiff, by 17th inst.

London, E.C.—Tenders are invited by the G.P.O. for the purchase of about 35 tons of old copper (wire, plates, etc.), a large quantity of other metals (brass, zinc, iron, and steel), india-rubber-covered wire, mercury deposit, indiarubber, tinfoil, felt, rope, tar barrels, raw hide pieces, etc. A form of tender can be obtained from Mr. Charles E. Stuart, controller of stores, G.P.O., Telegraph-street, E C. Tenders will be received until Monday, June 17.

Preston — Tenders are invited for the wiring and fittings required for the lighting by electricity of the Town Hall and public hall buildings. Specifications and conditions at the borough engineer's office, Town Hall, Preston, on payment of a deposit of £1, which will be returned on receipt of a bona fide tender. Separate sealed tenders for each of the buildings must be sent to Mr. Henry Hamer, town clerk, Town Hall, Preston, endorsed "Tenders for Electric Lighting," by 12 noon on July 1.

Bedford.—The Electric Light Committee are prepared to receive tenders for the supply and erection of the following plant: Section A—Two water tube boilers; Section B—two 140 b.h p. double-acting compound enclosed engines; Section C—two 90-unit alternators with stationary armature. Specifications, with terms and conditions of tender and contract, may be obtained at the offices of Mr. T. G Porter, clerk to the Urban Sanitary Authority, on payment of a fee of 7s. 6d. for each section. Tenders, sealed, and marked "Electric Lighting, Section A, B, or C," are to be delivered by Tuesday, 25th inst.

Bradford.—Tenders are invited for the supply of best gas coal, cobbles, nuts, and cannel, all to be well screened, dressed, and free from shale and pyrites, to be delivered at the several works of the Corporation in the borough during one year or two years, commencing August 1, for the Gas and Electricity Supply Committee. Form of tender, with any further information required, may be had on application to Mr. Wood, gas engineer, Town Hall. Sealed tenders, endorsed "Tender for Coal," to be sent to Mr. W. T. McGowen, town clerk, Town Hall, Bradford, by July 3. An assurance must be given by each contractor that he pays to the workmen employed by him not less than the minimum standard rate of wages.

London.—The Secretary of State for War gives notice that purchases for specific quantities of various articles will be made from time to time during the current year. Among them are electrical instruments for submarine mining and telegraph cable and wire. Manufacturers who may be desirous of tendering should apply to Mr. G. Lawson, director of army contracts, War Office, Pall-mall, S.W., by letter, giving at least names of two well-known firms or public bodies who have purchased from them and are in a position to certify as to the quality of their productions. Applications unaccompanied by references will not be noticed. Firms whose names are already on the War Office list need not apply, as forms for tendering will be sent to them in due course.

Inverness —Tenders are invited for the following articles, among others, from July 1, 1895, to June 30, 1896, delivered free of all charges, viâ Dunkeld, at the company's storehouses, Inverness, for the Highland Railway Company: telegraph instruments and fittings and telegraph construction material. Forms of tender may be had on application to Mr. J. G. Bulmer, storekeeper, Inverness. Tenders, properly endorsed, sealed, and addressed to the directors, must be lodged with Mr. And Dougall, secretary, Inverness, by 22nd inst. Separate forms of tender will be provided for each contract; parties are therefore requested to specify the particular contract or contracts in respect of which they propose to submit tenders. Those we have noted are respectively numbered 17 and 17A.

Madrid.—The Spanish Postal and Telegraphic Administration invites tenders by June 28 for the supply of 20 tons of copper. Preliminary security 5 per cent., definitive security 10 per cent., maximum price 520 pesetas per ton. Conditions, etc., and forms of tender from La Direccion General de Correos y Telégrafos, Madrid.—The Spanish Postal and Telegraphic Administration invites tenders by June 29 for the supply of 40,000 white and 10,000 grey porcelain insulators. Maximum price, 1 peseta 5 centesimos for the white and 1 peseta 10 centesimos for the grey. Provisional security, 2,650 pesetas; definitive, 10 per cent. of the estimate. Tenders are also invited by June 30 for the supply of 25,000 zinc cylinders for Calland elements. Maximum price, 980 pesetas per 1,000; provisional security, 1,225 pesetas; definitive, 10 per cent. of the estimate. Conditions and forms of tender from La Direccion General de Correos y Telégrafos, Madrid.

St. Helens.—The Electric Lighting Committee of the Corporation are prepared to receive tenders for the supply and erection of the following plant: Section A—boiler-house plant, including boilers and fittings, forced-draught apparatus, feed pumps, etc.; Section B—engine-house plant, including steam alternators, oil-filter, fittings, etc., steam, exhaust, feed, blow-off, and sundry pipes, valves, and water-tanks, etc.; Section C—main switch-board and instruments; Section D—underground work, including cables, junction-boxes, culverts, and trenching; Section E—transformers and fittings; Section F—meters; Section G—overhead crane. Tenderers are at liberty to tender for any section or sections, or for the whole of the sections, but not for part of a section. The ground plan of plant, plan of streets, etc., and specification, with terms and conditions of tender and contract, may be obtained at the offices of Mr. Robert Hammond, the consulting engineer to the Corporation, Ormond House, Great Trinity-lane, London, E.C., on and after June 11, on payment of £2. 2s., which sum will be returned on receipt of a bona fide tender. Tenders, sealed, and marked "Tender for Electric Lighting,"

Digitized by Google

must be addressed to the town clerk at the Town Hall, St. Helens, and be delivered on or before Tuesday, July 2.

RESULTS OF TENDERS.

Exeter.—For carrying out an installation of the electric light at the Museum: Electrical and General Engineering Company, £299. 10s. (accepted).

Halifax.—The tender of the Electric Construction Corporation, Limited, for the supply and fixing of a combined alternator and a Pollit and Wigzell engine has been accepted by the Town Council, the cost being £3,050.

Shoreditch.—Twenty-seven tenders were opened by the Shoreditch Vestry for the electric wiring of the Town Hall upon the specification provided by the Town Hall Committee. There was considerable divergence in the prices, the highest tender amounting to £848, while the lowest, sent in by the Electrical and General Engineering Company, and accepted by the Vestry, amounted to £178.

Brighton.—For the supply and erection of arc lamps, switches, etc., for the Town Council:

Sharp and Kent, Victoria-street, Westminster (accepted)	£2,167
Crompton and Co., Limited, Mansion House-buildings, E.C.	2,838
J. A. Edmundson, Grove Electrical Works, Leeds	2,757
Siemens Bros. and Co., Limited, Queen Anne's-gate, Westminster	2,988

Tenders were also received from Johnson and Phillips and the Electrical Engineering Company, but being informal were not entertained.

Hanley.—Tenders for various contracts in connection with the electric lighting extensions have been accepted by the Town Council of this borough, as shown in the following list:

Contract No. 11.—Surface Condensing Apparatus.

C. A. Parsons and Co., Newcastle-on Tyne	£1,390	0	0
J. Fowler and Co., Leeds	1,009	0	0
Crompton and Co., Chelmsford	895	0	0
J. Watt and Co., Birmingham	885	0	0
S. Z. de Ferranti, London	845	0	0
Electric Construction Company, Wolverhampton	842	0	0
Johnson and Phillips, Old Charlton	806	0	0
Siemens Bros. and Co., London	802	0	0
Brush Electrical Engineering Company, London	786	0	0
W. H. Allen and Co., Bedford (accepted conditionally)	755	0	0
British Thomson-Houston Company, London	740	0	0
T. Shore and Sons, Hanley	618	0	0

Contract No. 12.—Two Lancashire Boilers, etc.

Davy Bros., Limited, Sheffield	1,718	0	0
D. Adamson and Co., Dukinfield	1,645	0	0
Hawksley, Wild, and Co., Sheffield	1,450	0	0
Tinkers, Limited, Hyde	1,400	0	0
J. Adamson and Co., Hyde	1 390	0	0
J. Thompson, Wolverhampton	1,250	0	0
Brush Electrical Engineering Company, London	1,228	0	0
W. R. Renshaw and Co., Stoke-on-Trent	1,180	0	0
E. Danks, Oldbury (accepted conditionally)	1,178	0	0
H. and T. Danks, Limited, Dudley	1,060	0	0

Contract No. 13.—Water-tank, etc.

Peirson and Co.	423	0	0
Brush Electrical Engineering Company	243	0	0
Cowlishaw, Walker, and Co.	225	0	0
E. Danks	205	0	0
Cochrane and Co.	185	0	0
J. Warner and Sons	180	0	0
T. Shore and Sons	170	0	0
J. Thompson	167	10	0
W. R. Renshaw and Co. (accepted)	164	18	0

Contract No. 14.—Arc Lamps and Posts.

The tenders and designs received demand more time for consideration, and are consequently deferred to the next meeting of the Council.

Contract No. 15.—Electric Light Mains—High and Low Tension Cables.

Laing, Wharton, and Down	2 084	10	0
Brush Electrical Engineering Company	1.757	10	10
W. T. Glover and Co.	1,666	10	4
W. T. Henley's Company	1,665	3	6
India Rubber and Gutta Percha Company	1,657	17	0
Siemens Bros. and Co.	1,609	5	10
Fowler-Waring Cables Company	1,525	19	0
Telegraph Manufacturing Company	1,521	12	0
Johnson and Phillips	1,509	18	4
British Insulated Wire Company (accepted)	1,393	8	4
W. R. Renshaw and Co. (the same, but including Kingdon's patent wrought-iron cover)	2,290	6	8
Callender's Bitumen, etc., Company (low-tension mains only, including laying)	1,730	13	4
Stanton Iron Company (for 2in. cast-iron pipes, at per ton, accepted)	4	12	6

Contract No. 16.—Transformers, with High and Low Tension Switches.

C. A. Parsons and Co.	888	0	0
Siemens Bros. and Co.	822	0	0
Johnson and Phillips	738	0	0
Electric Construction Company	694	10	0
Crompton and Co.	675	0	0
Brush Electrical Engineering Company (accepted)	632	2	0
J. Fowler and Co.	623	8	0

BUSINESS NOTES.

Great Northern Telegraph Company.—For the month of May the receipts were £28 400.

Western and Brazilian Telegraph Company.—For the past week the receipts were £2,650.

Phonopore Company, Limited.—The transfer books of this Company will be closed until the 27th inst.

Commercial Cable Company.—The Commercial Cable Company have declared a quarterly dividend of 1¾ per cent.

Folkestone.—At the last meeting of the Town Council the consideration of the electric light question was adjourned.

Belfast.—Mr. Stelfox, the gas engineer to the Belfast Corporation, has applied for current for electric lamps at the gasworks for use where open gas jets would be dangerous.

Wallasey.—At a meeting of the District Council, Captain Herron stated the introduction of the electric light at Seacombe was being arranged for if it could be procured as cheap as gas.

Harrogate.—The Town Council have resolved that the electric lighting scheme should be entirely reconsidered, and that the question of utilising town's refuse in the boilers should be omitted from the plans.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 2nd inst. amounted to £1,671, as compared with £843 in the corresponding week of last year, being an increase of £828.

Theatre-Lighting.—Messrs. Roger Dawson, Limited, inform us that they have received the order for supplying the complete electric light fittings for the Empire Palace of Varieties now being built at Blackpool.

Oswestry.—The Town Council have held a meeting at which it was stated that the Board of Trade recommended that earthenware instead of iron pipes should be used in laying down the proposed electric light.

Aberystwith.—At the last meeting of the Town Council it was stated that Mr. W. H. Preece, owing to great pressure of business, had been unable to send his promised report on the electric light, but would do so shortly.

Reflector Syndicate, Limited.—This Company has been registered, with a capital of £2,000, to carry into effect a certain agreement, and to carry on business as manufacturers of and dealers in reflectors and projectors.

National Telephone Company, Limited.—The transfer books of the 3½ per cent. debenture stock will be closed from 17th to 29th inst., inclusive, for the preparation of warrants for the half-year's interest, due July 1.

Chiswick.—A meeting of the Urban District Council has been held at which the surveyor reported that the electric lighting works had been stopped pending the decision of the Council relative to the height of the shaft.

Metropolitan Electric Supply Company, Limited.—The transfer books of the 4½ per cent. first mortgage debenture stock will be closed from 17th to 30th inst., both days inclusive, for the purpose of preparing interest warrants.

Private Bills in Parliament.—The Great Northern and City Railway (Extension of Time) Bill and the London County Council (Money) Bill, have been considered by the House of Commons Committee and ordered for a third reading.

Fire Prevention.—The Hampstead Vestry's electric lighting station has been fitted up with Heathman's improved fire-hydrants, with hose and fittings so positioned as to be available for prompt service in the event of an outbreak of fire taking place.

Telegraph Manufacturing Company, Limited.—The ninth ordinary general meeting of this Company was held on Friday last, and the usual distribution of profits was declared—viz., a dividend of 5 per cent., and in addition a bonus of 2½ per cent., both free of income tax.

Telescopic Ladders.—The British Thomson-Houston Company have ordered from the Heathman Patent Ladder Company, of Endell-street, W.C., two telescopic ladder tower wagons for the erection and repairs of trolley wires on the Dublin electric tramway system now being constructed.

Connolly Bros., Limited.—This Company has been registered, with a capital of £20,000, to adopt a certain agreement for the acquisition of the business of Connolly Bros., of Blackley Vale Mills, Blackley, Lancashire, insulated cable manufacturers and electricians, and to develop and extend the same.

Oxford.—The New Municipal Buildings Committee of the Town Council have reported that in the estimates a sum of £1,000 had been set aside for electric wiring, and £600 for electric fittings. The committee have obtained contracts for or definitely appropriated sums for various contracts, including £740 for the wiring.

City and South London Railway.—The returns for the week ended June 9 were £904, compared with £911 for the corresponding period of 1894, being a decrease of £7. The total receipts for the current period of the present half-year are £21,437 against £20,924 in the corresponding period of 1894, an increase of £513.

Southport.—A meeting of the Town Council has been held, at which a long discussion took place on a motion moved by the chairman of the Electricity Committee, Councillor Hesford, that a

Digitized by Google

scheme be adopted of differential charges for electricity so as to encourage consumption. After a long discussion the minutes were passed.

Paddington.—The Electric Lighting Committee of the Vestry have reported that the clerk had been instructed to write to the Metropolitan Electric Supply Company, enquiring whether it was their intention to construct transformers in the main thoroughfares, and if so, whether they possessed the necessary parliamentary powers.

Dispute at the Edison and Swan Electric Light Company's Works.—The Electrical Trades Union on Tuesday issued a manifesto to the organised workers of London, in which it is stated that in the negotiation for a settlement of the dispute at the Ponder's End works of the company it has become necessary to prepare for a long struggle, and an appeal is made for moral and financial aid to assist the 400 men, women, and boys affected.

The Military Tournament.—A novelty of electrical interest introduced during the last week of this show consisted of a search-light, with oil-engine and dynamo combined, on a light three-wheel trolley, intended for field service and for flashing signals. The plant was designed and manufactured by the Dawson Gas-Engines Syndicate, Limited, of 76, Queen Victoria-street, E.C. The engine was one of their special high-speed type, running at 800 revolutions per minute, and coupled direct to the dynamo shaft.

Blackburn.—The electric light is finding much favour in Blackburn, and seems likely to be pretty extensively used, not only publicly, but by private consumers. The Town Council, it is worthy of note, have just decided upon an extension of the light, it having been resolved to adopt the scheme of lighting Railway-road and Salford Bridge with this illuminant. It has been decided by the Gas Committee that the price of current shall be reduced to 6d. per unit for illuminating purposes from the end of the quarter.

Electric and General Investment Company.—The directors have decided to recommend the payment of a further dividend on the capital paid up on the ordinary shares at the rate of 30 per cent. per annum for the six months ended May 31 last, making, with the interim dividend already paid, a total dividend of 20 per cent. for the year, and also to make a distribution of £35. 16s. on each founder's share for the year. The transfer books will be closed from 19th inst. to July 2, both days inclusive, for the purpose of preparing the dividend warrants.

West Bromwich.—The Board of Trade have again renewed the license for the use of steam on the South Staffordshire tramways for one month from May 15. At a meeting of the Town Council, Alderman Heelis, as chairman of the Highways Committee, said there appeared to be an impression among the public that the committee were hampering the tramway company. The committee had no wish to hamper the company, but more to assist them. They had the public convenience to watch, and what they wanted was a proper means of locomotion.

Appointment.—The Shoreditch Vestry invite applications for the appointment of clerk of works, with practical building experience, to supervise the erection of a dust destructor and electric lighting station, buildings, and connected works on behalf of the Vestry, and under the direction of the consulting engineers. The salary will be £3. 3s. per week. Applications, on forms to be provided, with copies of not more than two recent testimonials, must be sent to Mr. H. Mansfield Robinson, vestry clerk, Town Hall, Old-street, E.C., by noon on 24th inst., endorsed "Clerk of Works."

Tumbler Switch.—We are informed that the action for infringements of the link switch patent brought by the General Electric Company against Messrs. W. McGeoch and Co, and others, has been settled on terms satisfactory to all parties in preference to taking the matter into court. Messrs. W. McGeoch and Co., Verity and Sons, and Evered and Co. have taken licenses from the General Electric Company, under which they will continue to manufacture and sell tumbler switches with the heel-piece as before. The Edison and Swan Company have also for some time been licensees for this patent.

Burton-on-Trent.—The Gas and Electric Light Committee have, as we have previously announced, recommended that the tenders of the Sheffield Coal Company, the Staveley Coal and Iron Company, and J. and G. Wells be accepted. The committee also recommended that the tender of the Telegraph Manufacturing Company, of Helsby, near Warrington, be accepted for the high and low pressure cables for the extension of the electric light system across the Burton Bridge and along Ashby and Alexandra roads. The tender of the Stanton Ironworks Company for cast-iron pipes for the same works was also recommended for acceptance.

Holbeach.—The Urban District Council have held a meeting at which tenders for street-lighting by oil, gas, and electricity were received. The gas company tendered for gas lighting at £2. 3s. 4d. per lamp for the season, or 4s. 2d. per thousand feet, two special lamps to be supplied by meter. Mr. Bean tendered for oil at £140 for the season, and Mr. T. Barton, of Blackburn, through Mr. Bean, tendered for electric lighting at £210 for the season, for a term of seven years. The total cost of the gas for the season was estimated to be about £165, and the company's tender was accepted. This is the same rate per lamp as last year, but the time of lighting has been extended.

Fulham.—The Electric Lighting Committee recommended the Vestry at its last meeting to invite an engineer to furnish a report on the introduction of the electric light with a dust destructor into the parish for a fee of 50 guineas. Mr. Drew thought there was not the slightest likelihood of having the electric light introduced into the parish, and any money spent upon it would be entirely thrown away. The class of house in the parish did not call for the light. At the suggestion of the Chairman the matter was adjourned until the next meeting. Messrs. Kincaid, Waller, and Manville have been recommended to advise the Vestry in the matter of electric lighting at a fee of 50 guineas.

Wigan.—A meeting of the County Borough Council has been held, at which Mr. Holmes moved the confirmation of the Gas and Electric Lighting Committee's minute. Alderman Phillips said he was being continually twitted and asked when they were going to have the electric light in the town, and also if it was a fact that members of the committee were controlled by certain gentlemen outside the Council. Mr. Holmes said he was not aware of any outside influence being brought to bear on the committee. It was true the sub committee had had several meetings, but up to the present time did not see eye to eye as to carrying out the electric light. It might be that within a short time the thing would be carried forward. Speaking individually, if they were to have the electric light they ought to be moving. It was time it was put into active operation, or placed on the shelf altogether. The minutes were confirmed.

Aberdeen.—At a meeting of the Gas and Electric Lighting Committee of Aberdeen Town Council, it was agreed to recommend that the electric mains should be extended along Bridge-street, a number of applications for supplies of current having been received from occupiers of premises in that thoroughfare. The cost of extension is estimated at £310. A copy of regulations forwarded by the Board of Trade with reference to the mains and culverts in connection with electric lighting systems was submitted to the meeting, as also was a report by Mr. Blackman, electrical engineer, and Mr. Smith, gas manager, stating objections to certain of the regulations. It was further reported that the Corporations of Glasgow and Hull intended to lodge objections. The committee resolved to consult Prof. Kennedy, London, on the points raised, and Mr. Blackman, who is to be in London soon on Corporation business, will submit the objections to the professor.

Dundee.—Mr. W. E. L. Gaine, general manager of the National Telephone Company, Limited, has issued the following notice: "Arrangements have been made with the Post Office authorities by which the subscribers to the company's local exchange system at Dundee may telephone their telegrams direct to the post office in that town by means of the exchange instruments fixed upon their premises. Telegrams may also, where the Post Office regulations permit, be transmitted from the post office to subscribers in a similar manner in lieu of delivery by messenger, on the subscriber signifying in writing to the company his wish to that effect. The company do not propose to make any charge for these additional and valuable facilities, but subscribers wishing to take advantage of these services must sign the usual agreement form, and deposit with the company an amount sufficient to cover the cost of any telegrams they are likely to transmit during the period of one month from the date of such deposit, the amount of which deposit must not be less than £1."

Kensington.—A meeting of the Vestry has been held, at which the Works Committee reported that notices and plans had been received from the Notting Hill Electric Lighting Company, relative to extensions of their mains in Addison-road and Addison-crescent, alternative proposals being submitted for laying armoured cables or the ordinary cables in three 1¼in. pipes. The committee recommended that the company should be informed that the Vestry were unable to sanction the use of armoured eable in their district, and that permission should be given for the laying of cables in iron pipes, subject to the following conditions—namely, "That the size of the pipes be approved by the Vestry's surveyor and the lighting engineer. That the plans be approved by those officers, and that the works be carried out under their supervision and to their satisfaction. That the works be completed within three months of the date of sanction. That the boxes be efficiently protected against accumulations of gas and water." The report was agreed to without discussion.

Middlesbrough.—A meeting of the Electric Lighting Committee of the Middlesbrough Corporation has been held for the purpose of considering the advisability of recommending the Town Council to adopt electric lighting for the town. A special committee visited several towns last year and inspected the various systems in operation. In all cases they were found to act well, and consumers testified to the light being superior to gas The cost of an installation would be 50 per cent. more at Middlesbrough than gas, but this was counterbalanced by the greater illuminating power. It was agreed to recommend the Council to lay down an electric installation at a cost not exceeding £25,000, this being sufficient to meet the present requirements of the town. The Electric Lighting Committee's report came before the Town Council on Tuesday. After some discussion, Alderman Hugh Bell moved, as an admendment, that the matter be referred back and that the committee be requested to report the smallest amount for which electric plant could be obtained. Alderman Hinton seconded the amendment, which was agreed to.

Manchester.—A novel application of electricity which is certain to attract much attention on the part of railway travellers who use Victoria Station, Manchester, is now to be seen at work at that centre of traffic. For some time the necessity has been felt of increasing the facilities for dealing with the parcels business at the station, and the apparatus now in use has been designed with

Digitized by Google

that object. Hitherto the subways have been employed, but an alternative method has been supplied by the construction of an overhead tramway, extending from the old parcels office on No. 3 platform to No. 8 platform, where the new parcels department is now situated. This miniature tramway is suspended from the girders of the roof Along the rails run an electric motor capable of lifting and conveying a ton, but not used for more than half that weight When parcels have to be transferred to or from the office they are placed in the hamper, and it is then wound up to its place under the motor, which at once runs off under the control of a workman, who is able to stop it and let down or pick up his hamper at any point he pleases. At present only one set of rails is in use, but the company are fixing a second pair to run alongside the first.

Chester.—A meeting of the Town Council was held on Wednesday, when the report of the Electric Lighting Committee showed that the committee recommended the Council that they be authorised to accept the offer of Thos. Parker, Limited, Wolverhampton, to supply an electric light installation for the city for £14,200, exclusive of buildings, etc., estimated at £3,000 (total £17,200), and to run it for a period of one, two, or three years, to supply public and private lighting at the prices named, and to arrange the terms of the necessary contract and do what might be necessary to get the installation established. It appeared from the minutes that the committee made the recommendation on the advice of Lord Kelvin. Mr. B. C. Roberts, in moving the adoption of the recommendation, said that in delaying so long in carrying out the electric lighting of the city they had lost nothing, but gained a great deal. They had got all the newest improvements and had also gained other advantages, one of which was that they were to obtain the energy at so low a price that he hoped they should be able to supply the electric light to the city and the citizens at a comparatively lower price than gas. The motion was adopted.

The Foyers Aluminium Works.—A beginning has been made with the works for the abstraction of part of the water from the River Foyers for the purpose of generating power to produce aluminium from alumina, which is to be brought to Loch Ness from Ireland. Mr. Peregrine Birch, M.I C.E., has designed the works, and has the superintendence of them, and Mr. Andrew Ainslie Common, one of the directors of the British Aluminium Company, Limited, for whom the works are being constructed, was also at Foyers last week to see the start made. Foyers House, which was formerly a shooting-box, but which has been in a ruinous condition for about a score of years, has been secured by the company for the use of workmen, and is now fitted up as a commodious lodging-house with some 50 beds. It is expected that about 130 to 150 men will soon be engaged. The works now begun include the extension of the pier at Foyers in Loch Ness by 200ft., the construction of a tunnel (half-a-mile in length) through rock for the conveyance of the water to a point where the fall will be made through pipes, the power thus obtained being expected to reach between 2,000 h.p. and 3,000 h.p. There will be other work to do before the production of the metal can be in progress.

Birkenhead.—The Council have had a meeting, at which Mr. Snape, referring to the acceptance of various tenders for the erection of the electric lighting station, asked if the chairman had any great hopes of the electric light being started by the autumn, and whether the £20,000 originally stated as the first cost of the undertaking was likely to be exceeded. Alderman Deakin said Mr. Shoolbred advised them it was likely—in fact, certain from his point of view—that the electric light would be ready for the winter months, provided these tenders were now accepted. The various tenders up to this point amounted to about £13,000, and they were advised by Mr. Shoolbred that the remainder of the work could be done for less than the difference between the amount and the £20 000 referred to. Mr. Snape: Is the amount of the purchase of the land included in that £20,000? Alderman Deakin: Yes. Mr. Snape: How much was that? Alderman Deakin: £1,500. Mr. Snape maintained it would be nearer the mark to say the autumn of 1896 than that of 1895, and in view of the fact that the whole of the estimates of the proposed expenditure were not complete, he moved that the acceptance of the various tenders named be not confirmed There was no seconder, and the minutes of the Finance Committee were then confirmed.

Bangor (Wales)—According to the reports of the Electric Lighting Committee presented at the last meeting of the Council, it appeared that Mr. Thomas Lewis was elected chairman, and Mr. J. Gill clerk. On the motion of Mr. Henry Lewis, seconded by the Mayor, Mr. T. H. Medhurst was appointed consulting engineer at a fee not exceeding 25 guineas, including expenses for preliminary report and advising the committee generally; and should the committee proceed with this matter, that Mr. Medhurst be engaged as engineer, the present fee to merge into his commission. On the motion of Dr. Grey Edwards, seconded by Mr. Robert Hughes, the engineer was asked to report on the feasibility and cost of lighting the city with electricity, and advising generally as to the adoption of the Electric Lighting Acts. On the motion of Mr. J. E. Roberts, seconded by Mr. Richard Davies, Dr. Grey Edwards and the borough surveyor (Mr. J. Gill) were asked to prepare a list of questions to be submitted to towns of similar size to Bangor as to the working of the electric light in their districts. Mr. Thomas Lewis and Dr. Grey Edwards were also appointed to accompany the electrical engineer on his visiting Bangor. The committee had under their consideration a report sent in by Mr. Druce (representing the Edison-Swan Company), for which the committee thanked the latter. On the motion of Mr. Thomas Lewis, seconded by Mr. T. G. Williams, the committee's reports were adopted by the Council.

Rangoon.—Besides advertising, the Rangoon Municipality are making enquiries through their agents to acertain the terms upon which electric lighting plant can be erected for lighting the streets of Rangoon, and the cost of working and maintaining it; what the streets could be lighted for if the plant were erected and worked by the tenderer, the plant remaining his property, and what terms of concession would be required for the sole right of supplying electricity to the Municipality. Underground cables must be laid within the town proper and overhead wires in the suburban and isolated areas. At the present the total cost of lighting the streets of Rangoon with kerosene lamps is Rs. 40,000 per annum, and the system is far from satisfactory. The suburbs are entirely neglected. The electric installation erected by the Irrawaddy Flotilla Company at the new Government House is, judging from the results of recent trials, quite a success. Besides being a very great improvement on kerosene lights, it adds immensely to the splendour of the interior of the building and shows to advantage the artistic ceiling. The engine and dynamo are so placed that the inmates of the building will not be disturbed by the noise attendant on the working of the machinery. This success has led to the company being recommended to carry out the electric lighting of the new public offices.

Halifax.—At a recent meeting of the Town Council, Alderman Brook proposed, and Alderman Enoch Robinson seconded, the acceptance of the tender of the Electric Construction Company, Limited, for the supply and fixing of a combined alternator and a Pollitt and Wigzell engine at the electric light station, for the sum of £3,050. Councillor Woodhead, replying to an observation by Councillor J. T. Spencer, remarked that this was a matter which could not wait. The committee had thought that, for the first winter, they would do well if they secured customers for 2,000 lights, and they prepared for that. Already, however, they had applications for over 3,000. They were bound to have a certain amount of reserve power, and, should one of their present engines fail, they would be unable to supply sufficient power. The number of applications for next winter, he believed would not be far short of 6,000 lights. The town clerk added that, under their Act, they were bound to meet the demands for lights, and unless they carried out the proposed extension it was possible that they would render themselves liable to £6,000 in penalties. The resolution moved by Alderman Brook was then agreed to. The authorities of the Halifax New Infirmary have decided to lay down a plant of their own to supply the institution with the electric light. They recently applied to the Electric Lighting Committee of the Corporation to grant them a supplementary service, so as to be prepared for contingencies. The committee have come to the conclusion that they would not be warranted in incurring the expense that would be involved. They would have been glad, however, to add the infirmary to their list of customers.

Weybridge.—The Urban District Council have held a meeting, at which the Highways and Lighting Committee recommended that a contract for the lighting of the district for a period of seven years should be entered into with the Weybridge Electric Supply Company. Mr. Ward opposed the adoption of the report, pointing out that it was not merely entering into a contract for seven years, but the Council would not be able to purchase the works for 40 years, and he asked them not to run their heads into a noose. He went into figures to show that the probable cost of the undertaking to them would be about £10,000, which at 3 per cent. interest meant an outlay of £300 per annum. On the other hand, they had to pay £3. 7s. 6d. per annum for each lamp, and as they would require £250 lamps at least, that would mean an outlay of £743, and he contended that it would pay them a great deal better to purchase the undertaking. He moved that the question be referred back to the committee for their further consideration. Mr. Bilney seconded the proposition, and severely criticised the manner in which the negotiations had been conducted on the part of the Weybridge Electric Supply Company. He doubted whether the security they offered for the carrying out of the contract, if entered into, was substantial enough. Dr. Powell opposed Mr. Ward's motion, and stated that they had taken the opinion of Captain Bax, who informed them that the district could not be lighted at a cheaper rate than £3. 7s. 6d., and that work of that description was always carried out more satisfactorily by a private firm than by a public body. He moved that the recommendation of the committee be adopted, but this finding no seconder, Mr. Ward's resolution was put and carried *nem. con.*

Hastings.—The Roads Committee of the Town Council have received from the secretary of the Hastings and St. Leonards-on-Sea Electric Light Company, Limited, notice of the intention of the company to extend their service mains (*a*) from the transformer-chamber opposite Old Christ Church, London-road, across London and King's roads to inspection boxes placed opposite to 28, King's-road, thence to 30, King's-road, and in the opposite direction to 24, King's-road, and (*b*) from a point opposite 3, Bank-buildings, to the Volunteer Drill Hall, Middle-street, in accordance with the plans forwarded with the notice, which notice fully specified the mode in which the works were intended to be executed. The committee had duly considered the notice and plans, and at the last meeting of the Town Council recommended that such plans be approved, subject to the works being carried out to the satisfaction of the borough engineer, and to the company giving the usual undertaking not to remove the covers of the boxes except between the hours of 10 p.m. and 9 a.m., unless in case of actual emergency. The Roads Committee also received from the company notice of the intention of the latter to extend their service main from their works, across the railway bridge, to an

Digitized by Google

inspection box proposed to be constructed on the upper side of the junction of Braybrooke-road with Priory-avenue, in accordance with a plan submitted, and they recommended that the plan be formally disapproved, the arrangement of the carrying of the main over the bridge not being, in the committee's opinion, altogether satisfactory. The borough surveyor had received instructions to confer with the company's manager on the subject. The recommendations were carried by the Council.

Douglas (Isle of Man).—A meeting of the ratepayers of Douglas was held on the 6th inst. in the gymnasium for the purpose of considering an offer made by the Isle of Man Tramways and Electric Power Company, Limited, with regard to the leasing of the shore section of the tramway and the construction of a cable tramway to Upper Douglas. The electric tramway company proposed in return for a double line throughout the Douglas Bay line, and an extension of lease for 21 years in addition to three years unexpired, to grant the Town Commisioners an annual payment of 15 per cent. upon the gross traffic receipts of such line, the minimum payments to be £1,500 per annum. The company also undertook to construct and work a tramway to the upper part of Douglas. It was urged that by adopting the company's proposal there would be a saving by the Commissioners of 4d. in the pound in the rates. A resolution was proposed to the effect that in the general interests of the town it was important that the proposal, with such modifications as might be desirable, should be adopted by the Town Board. It was strongly urged that the company's offer should be accepted, and ultimately the resolution was carried by a large majority. At an adjourned meeting of the Douglas Town Commissioners on Monday evening, the draft agreement entered into between the electric tramway company and the Commissioners for the lease of Douglas Bay tramway for a further term of 21 years was considered. Several members contended that the offer of the company to pay 15 per cent. upon the gross earnings and to construct and work a tramway to Upper Douglas was insufficient consideration for the extension of the lease. An offer of Mr. H. Creppin (Manchester) to give 1 per cent. more than the tramway company was laid before the Board. After an exciting debate the draft agreement with the tramway company was confirmed by 10 votes to 8.

Rathmines.—The Rathmines and Rathgar Commissioners have held their monthly meeting, at which Mr. Hewson said he understood there had been some recommendations by the Parliamentary Committee with reference to the electric tram system, and with the view to opposing that system. He saw on the table a photograph representing portion of an electric tram line at present working, and he wished to point out that it gave a most unfair picture of the ordinary appearance of the overhead wire system. The photograph was taken at a point where there was a curve, and afforded quite an exaggerated idea of what was regarded by some people as the objectionable appearance of those wires. There was nothing in the system more objectionable than the ordinary tram system, and the wires were no more unpleasant to look at than the telephone wires. The action of the Board was simply in the direction of opposing the advance of science. Mr. Carey: I can only say that that picture is by no means exaggerated. These overhead lines are exceedingly unsightly. The Chairman: I may say that the question has been dealt with by the committee and a resolution come to to oppose the Bill for the introduction of the system. There was no intention whatever to oppose the advance of science. Mr. Carey said the overhead wires already erected in Leeds were most unsightly, and the authorities there refused to allow the erection of any more. Birmingham would not allow any more such wires to be erected, Blackpool would not allow overhead wires, and it was perfectly obvious that the general feeling was opposed to the system and in favour of underground wires as an alternative. They did not want to prevent the advance of science, but they were anxious and determined to prevent an unsightly and a dangerous system. The chairman again reminded the Board that the committee had unanimously determined to oppose the Bill. There was no doubt that the underground system could be adopted if the tram company chose to do so. The matter then dropped.

Wimbledon.—At a meeting of the District Council, Mr. Crimp stated that at a meeting of the Road and Drainage Committee Mr. W. H. Preece read his report on the proposed electric lighting. The matter was a very large and a very important one—probably the most important that had come before the Council for many years past. The committee, of course, could do nothing more than receive the report and ask questions upon it. The report contained a mass of details which could only be appreciated when the report was before the members and carefully studied. The committee, therefore, thought that the report should be printed and a copy sent to each member. There were two schemes. One scheme contemplated the lighting of the whole of the public lamps by electricity, and also a large number of private houses, at a cost for installation of something like £30,000, besides a very large expenditure for working expenses. The other scheme contemplated the lighting by electricity of only the main roads and the principal streets. Mr. Donaldson: I think it should be stated that Mr. Preece suggested that, after making allowance for the present cost of lighting by oil, the actual cost, at the worst, of the electric light would only be a few hundreds a year at first. Mr. Crimp: That is quite correct. I did not mention the matter because I thought this was not the proper time for details. But it is a most important fact, of course. I may add that Mr. Preece has an electric installation at his own house, and has kindly consented to put an electric light outside his house, and to change the candle-power at intervals, so that members of the Council may see what candle-power would be necessary. Mr. Crickmay thought the common was a very indifferent spot for an experiment of that kind. The Chairman pointed out that to have made the experiments in the Broadway would have involved a much greater cost. The spot was not an unsuitable one; it was a public thoroughfare, and very dark. Mr. Crickmay: If we are going to have an expenditure of £30,000, we ought to have the fullest possible experiments even if it costs us another £50. The matter was not further discussed.

Longton.—At a meeting of the General Purposes Committee, the town clerk reported that he had received from the Board of Trade a communication with reference to the application of the Corporation for sanction to use mechanical power (which has hitherto been refused) on portions of the tramway constructed in the borough in 1881. The Board of Trade now stated that, having regard to the street improvements which had been made and were in contemplation, and to the desirability, in the opinion of the Corporation, of extending the tramway system beyond the disused lines, the Board would be disposed to give a favourable consideration to an application for a provisional order authorising such lines afresh, and sanctioning the use of steam or other mechanical power thereon. It must, however, be borne in mind that at certain points a space of less than 9ft. 6in. would intervene between the rail and the nearest kerb for distances over 30ft., and that Section 9 of the Tramways Act, 1870, conferred upon the frontagers at such narrow places a certain right of veto. It would be the duty of the Board to give effect to this section in the event of an application being made to them, and also to give due consideration to any other objections that might be brought before them. It was resolved, "That application be made to the Board of Trade for a provisional order authorising the extension of the tramways in the borough to such points as may hereafter be decided upon, and sanctioning the use of steam or other mechanical power on the existing tramways and proposed extensions, and that the town clerk be instructed to take the necessary proceedings accordingly." At the same meeting a letter was read from the secretary to the North Staffordshire Tramway Company, Limited, stating that the company had had under consideration the subject of adopting some improved form of traction, and had come to the conclusion that the only method suitable for the district in which the tram lines were laid was that of electric traction by means of overhead wires, and asking for the consent of the Council to the general principle. A deputation was appointed to meet the directors of the company and discuss the matter and report to the committee.

A Visit of Enquiry.—The town clerk of Eccles has prepared a report of the visit paid recently by the Mayor and himself to the electric light works at Kingston-upon-Thames. Kingston is about the size of Eccles. He states that the electricity station is a model place. The buildings have been put up with a view to convenient extension, and one end thereof is covered by a simple corrugated iron framework, so that the new length could be put up without disturbing the walls. The Council has spent £18,000 in establishing electric light, including the cost of the buildings. The price charged is 6d. per unit for private consumers, which is reckoned to be equal to gas at 3s per 1,000 cubic feet, light for light, but with more light for the money than with gas. The works have been going about 18 months, and the results have been satisfactory. The light was taken up readily by the shopkeepers and by private residents, and although the first 15 months was not a financial success, owing to the variety of circumstances always attendant upon a first year's working, the engineer states that during the last three months they are making a profit. The price paid for gas is 3s. per 1,000 cubic feet, and the works are in the hands of a private company. Owing to the increased demand for heating and power, it is believed the introduction of electricity has not caused any reduction in the gas company's revenue. Coal cost 13s. 6d. a ton in the works, and the consumption is about 1,500 tons per annum. The way the Council got information as to the probable consumers was by circular issued to the residents asking them to state what number of lights they would take. A meeting was also held, at which the scheme was explained to the public. It is only in the principal streets that the arc lights are placed, the other streets being still lighted by gas. Judging from the kind of consumers who have taken the light at Kingston, it is quite clear that the small shopkeepers as well as the large shopkeepers, and small as well as large householders, have thought it worth their while to avail themselves of it. Taken all round, the venture is considered a success of the most encouraging kind, and it is anticipated that early extension will be necessary. The ratable value of the borough is £130,000, the population 30,000, and the rates in the pound altogether 5s. 6d.

Brighton.—At last week's meeting of the Town Council it was reported that at a meeting of the Lighting Committee held on May 20 the electrical engineer stated that the Corporation having decided to instal the larger Babcock and Wilcox boilers, it would now be possible, and greatly to their advantage, to instal one 750-h.p. Willans steam dynamo instead of two smaller ones as at first intended. This would necessitate the lowering of the new engine-room floor, to commence at the boundary of the present engine-room, instead of some 20ft. further south. The committee approved the suggestion, and instructed the surveyor to arrange for the erection of the new building accordingly. At a further meeting of the committee held on June 1 tenders for the supply and erection of arc lamps, switches, etc., were again submitted, and it was resolved to accept the tender of Messrs. Sharp and Kent, of Victoria-street, Westminster, at £2,167. Councillor Stafford proposed the confirmation of these proceedings, and the motion was agreed to without remark. The new pier erected

Digitized by Google

by the Brighton and Rottingdean Seashore Electric Railroad Company, has been opened to the public. The new jetty, which has been constructed by the company as part of their tramroad undertaking, which is now rapidly approaching completion, was designed by Mr. St. George Moore, of Victoria-street, Westminster, co-engineer with Mr. Magnus Volk in the laying down of the railway. The plans show a structure 800ft. in length but the portion now erected extends seaward for a length of 300ft. only, having a width of 20ft. opening out to 60ft. at the head for a space of about 40ft. The pier is now connected with the shore by a temporary gangway abutting upon the Gap; but this is presently to be displaced by a sea-wall 26ft high and 300ft. long, the top of which will form a railed promenade 20ft. wide. The effect of this will be to give a much better approach to the pier, and to greatly improve the approach to the beach by the Gap. At the seaward end of the pier, the deck of which is nearly 30ft. above high-water level, a flight of iron steps will communicate with a landing-stage 12ft. above high water and on a level with the electric tramroad cars, which are carried on an elevated framework at a level of 23ft. 9in. off the rails laid along the seashore. The tramroad will not be completed before August.

Glasgow.—The minute of the special sub-committee on the application by the electrical engineer for increase of salary, which was delayed by the Town Council at their previous meeting, was considered at their last meeting. The sub-committee reported that they had "agreed to recommend that Mr. Arnot's salary be increased from £350 to £450 per annum, as from 1st current, subject to the following conditions: (1) That the whole of Mr. Arnot's time is to be devoted primarily to the duties connected with the electric lighting department of the Gas Trust; (2) that in the event of an application being at any time made to the Sub-Committee on Electric Lighting by any of the other committees of the Corporation for the advice or services of Mr. Arnot in connection with any matter under the control of such committee, Mr. Arnot is, with consent of the Sub-Committee on Electric Lighting, to render such advice or service, and that the committee to whom such advice or service is given be charged therefor; and (3) that the increased salary now proposed to be paid to Mr. Arnot is to cover any advice or service he may render to any other committee of the Corporation, as before mentioned." Bailie Burt in moving the adoption of the minute, pointed out that the work in connection with the electric lighting department had been rapidly extended. Mr. Shearer said it was advisable, until the omnibus Bill was passed in Parliament, that words should be inserted to the effect that Mr. Arnot's services should be also available to the Police Board or any of the municipal trusts. This was agreed to. Mr. Jack seconded Bailie Burt's motion. The minute was unanimously confirmed. The Special Committee on the Telephone Service reported that at their meeting on May 1 they had instructed steps to be taken to ascertain the opinions of telephone users in the city as to the inefficiency, etc., of the telephone service in Glasgow, with a view to the result being laid before the Select Committee. Looking to the fact that the Select Committee had received evidence in favour of the telephone company's service, the committee resolved to ask the Select Committee to also receive evidence on the other side, and it was remitted to the chairman and Bailie Chisholm to select two persons whose names might be transmitted to that committee, with a request that they be examined. Deacon-Convener M'Lennan enquired as to who had authorised this action. It seemed to him to be rather hitting below the belt. Bailie Alexander explained that as other municipalities were doing the same thing, the committee thought it desirable that the telephone users should have an opportunity of expressing their opinion as to the efficiency or inefficiency of the service. The minutes were approved.

Tunbridge Wells.—At a meeting of the Town Council, Alderman Stone-Wigg asked the cost of public arc lamps and the number of applications for private lights? Councillor Wood said the question had been asked and answered before. The public lamps would cost £20 per year, and there were now applications for about 1,000 lights, but no doubt they would come in more rapidly when the works started. The Mayor said that was the general experience. People did not instal the light before they wanted it, and with the approach of winter there would probably be a number of further applications. Councillor Saunders asked the chairman of the Lighting Committee if the public lighting would be started immediately the station was open, or whether the private lighting would be started first? Councillor Gower asked if an additional lamp would be placed at the end of Camden-road? Councillor Strange asked if the difficulty with Messrs Burns and Berridge as to the Pantiles had been got over? Councillor Wood replied that the date of turning on the current had not been fixed. Another lamp would be put at the end of Camden-road. The Pantiles difficulty was still under negotiation. Alderman Cronk wished for further information as to the cost of public electric lamps, and whether they were to be kept alight during the whole night, or the same hours as the gas lamps. The Mayor, in reply, said the estimate was based on the fact that the City Company charged £26 per year for the public lamps, but they were lighted one hour before sunset, and were kept alight one hour after sunrise, which was really unnecessary. The Lighting Committee reported that they had held three meetings. Mr. Gallard wrote requesting that arc lamps might be erected on the Boyne Park Estate, but was informed that the committee could not do so until the estate was more developed. The town clerk was instructed to communicate with Mrs. Molyneux Williams's trustees as to placing an electric lamp over the Grosvenor drinking fountain. Messrs. Burn and Berridge wrote that the proposal to lay house service lines across the Pantiles was quite impracticable, and suggesting that a second low-tension main should be laid on the east side of the Pantiles. It was decided to extend the mains along Mount Ephraim to the Grosvenor Fountain, along Calverley-road to Howard's-corner, and through Monson-road at a cost of £630. The expenditure of the new loan of £12,000 was discussed, and Mr. Preece engaged to prepare plans and estimates. Messrs. Delves, Howard, Pelton, and Read attended as a deputation from the gas company and discussed the terms of the new gas contract. There were 55 applications for the post of resident engineer at a salary of £250 per annum, and it was arranged to select a candidate at an early meeting. It was decided to obtain tenders for 20 additional arc lamp-posts, and also to allow customers, if they desired, to purchase their own meters under certain conditions.

Derry.—The Mayor (Alderman Bell) presided at a meeting of the Lighting Committee of the Corporation on Thursday last week, when Alderman Pollock moved that the electrical engineer be instructed to prepare an estimate of the cost of providing private electric lighting. He gave statistics to show that private lighting was a money-making thing in many English and Irish cities and towns. Councillor MacCullagh seconded. A long and angry discussion followed. There was a scene of considerable excitement when Councillor Hastings, as chairman of the Lighting Committee, declared that he would command the engineer to refuse to obey the resolution if it was carried. Five voted for and five against the resolution. The Mayor refused to give a casting vote, and nothing definite was done in the matter. Mr. Christie, the electrical engineer, reported that with regard to the proposed scheme for lighting the Guildhall and clock by electricity, he communicated with the firms who would supply the necessary plant, and asked them if they would take payment of their accounts in instalments. He had received in each case favourable replies. He reminded the committee that for the greater part of the year the staff at the generating station work seven shifts per week, and a large proportion of this is nightwork. It was the general custom in electric lighting stations throughout the country for the men so employed to be allowed a 10 or 14 days' leave with pay. During the next six weeks the men could best be spared, and he (Mr. Christie) asked for authority to grant the holidays sought, by allowing away two at a time as circumstances permitted. A letter was read from Johnson and Phillips, Old Charlton, Kent, stating that they would accept payment for the electric plant, etc., specified for the Guildhall lighting, in three instalments—one-third on delivery, one-third six months after, and one-third 12 months after that. Messrs. Siemens Bros. wrote saying they were willing to accept the offered terms of payment—viz., half-yearly instalments of not less than £40. On the suggestion of the Mayor, the committee authorised the resident engineer to make the arrangements for the holidays for his staff in accordance with the method indicated in his report. Referring to the lighting of the Guildhall clock and main hall by electricity, Councillor Turner said the communication received from Siemens Bros. was very satisfactory. That firm had treated the Corporation very well in the past, and he thought they should not be passed in giving the present order. Councillor MacCullagh said if the work were pushed on and completed, it would be a very nice thing to have the clock and hall lighted for the first time on the arrival of the visitation of the Irish Society. The resident engineer observed that if the orders were placed without delay he considered he would have the work finished before August 2 next. After a few remarks, the Mayor said that a special meeting of the Council would be called to consider the matter. Mr. Christie's report was then approved and recommended to the Council for adoption.

Blackpool.—At a meeting of the Town Council, in reference to the Electric Lighting Committee's minutes, Alderman Buckley and Councillor Hodgson rose at the same moment to make some comment. The Mayor gave the former the first opportunity. Alderman Buckley's question was when the time would expire for the completion of the tramways. Councillor Pearson said that, seeing the alderman was a member of the committee, he had a right to know its secrets and ramifications, but to do so he invited the alderman to attend the meetings more regularly in the future. Alderman Buckley did not care for this evasive answer. It was right that the ratepayers should know when the parliamentary powers ceased, and it was the duty of the chairman of the committee to give a straightforward answer to a question affecting the residents of Lytham-road. Councillor Hodgson wished to know how it was that Mr. Robert Hammond had been appointed consulting engineer to the electricity works, seeing that Mr. J. Hesketh was at present in charge of the works. Was not that gentleman efficient? If he were not, it was time they got someone who was. He found from the minutes that on April 31 £125 was voted to Mr. Hammond, and on May 29 £100, making a total of £225 in two months. This was spending money rather fast—indeed, faster than any gentleman in that room would spend his own money. Some of them had to work much harder than Mr. Hammond had for his money; in fact, he was a rather expensive toy. Councillor Pearson said he was very sorry indeed that he could not give proper answers to everybody in that chamber. His answer in this case must be similar to the one he had given Alderman Buckley: Councillor Hodgson was a party to the arrangement with Mr. Robert Hammond as consulting engineer, and he was astonished that such a question should be preferred when Mr. Hammond's work was being carried out to the letter. When his work was finished his pay would finish, but not before. Alderman Buckley was proceeding to speak, when the Mayor called him to order, and said that he had already spoken on this subject. The minutes were

Digitized by Google

then adopted. The Highway Committee recommended that the public urinals and closets opposite West-street should be lighted by the electric light. Councillor Sergenson alluded to the minute of the Finance Committee authorising the engagement of a boy to attend the telephone switchboard at the police station in connection with the Corporation telephone system. From his little experience of the Corporation system, the speaker said, it had been very unsatisfactory indeed. When it was connected with the National Telephone Company it was available to any part of the town; now it was in a perpetual state of disorder and confusion. If he were in order he should propose that the private system be done away with, and some arrangement arrived at with the National Telephone Company. There were enough Corporation officials already—major and minor. Alderman Cardwell said the complaints were that the switchboard was not attended to at the police station. It would be better to give this new arrangement a trial. There was no seconder to the amendment, and the minutes were accordingly confirmed.

The City.—The Commission of Sewers met on Tuesday, when the Streets Committee presented the following important report on the electric light question: "From time to time we have had under consideration the question of lighting the minor streets of the City under the electric lighting contracts entered into by your honourable Court in the years 1890 and 1891. These contracts provide, *inter alia*, that all streets, lanes, and courts other than those described as main thoroughfares shall be lighted by means of 906 incandescent lamps, the prices being fixed at £10 per annum for lamps of 200 watts power and £5 per annum for those of 100 watts, the right being reserved to the Commissioners to change or alter any specified lamps as they may direct. With a view to determine the best method of lighting narrow thoroughfares, experiments were made in Aldermanbury and Basinghall-street with incandescent lamps of these capacities but the result was by no means favourable to this mode of illumination, and a subsequent trial with alternating arc lamps in the latter thoroughfare proved of no practical value. We thereupon instructed Mr. Preece and your electrical inspector to formulate a scheme for lighting the minor streets where possible by arc instead of incandescent lamps, and a survey of the thoroughfares in question was made, and plans were prepared by Mr. Voysey with that object. The City of London Electric Lighting Company, however, having intimated their inability to furnish us with any reliable estimate as to the cost of giving effect to the proposal until further experience has been gained on the subject, we submit a report from the electric inspector, suggesting that certain experiments should be made to illustrate side by side three different methods of illumination, whilst every facility will be afforded to Mr. Voysey by the company to check the actual cost of each system. It is proposed to light Bow-lane and the court leading out of it to Bow churchyard by means of six Sunbeam incandescent bracket lamps, so arranged as to be capable of being switched on and off by the police. Watling-street, Bread-street, Friday-street, and Old Change are to be lighted by means of 11 centrally-hung arc lamps. The thoroughfares selected for the experiments being contiguous will afford the opportunity of practically testing the comparative efficiency and value of the alternating and continuous current systems of arc lighting, as well as of the method of illumination by means of Sunbeam incandescent lamps, and of obtaining information as to the respective costs of running the same, the City of London Electric Lighting Company having agreed to charge only the actual cost to them of the work, which they estimate at about £386, independently of the charge for running the lamps, which your electrical inspector is of opinion will be about £1 per night. We beg to recommend that the proposed experiments be agreed to, and that it be referred back to us to have the same carried out accordingly." Mr. Wallace said he thought, as the hour was late, and several members had left the court, the report should be printed and circulated and its consideration adjourned. Mr. Edwards having seconded the motion, Mr. Berridge agreed to that course being adopted. The report was accordingly postponed and ordered to be printed.

Bolton.—Mr. W. J. B. Clerke, M.I.C.E., has held an enquiry at the Town Hall into an application by the Town Council for sanction to borrow £17,300 for electric lighting purposes. There were present Aldermen Miles, J.P. (chairman of the Gas, Street Lighting, and Electricity Committee), the electrical engineer (Mr. J. H. Rider, M.I.E.E.), and Mr. C. E. Murphy (Messrs. Hinnell and Murphy), architect for the electricity works. The Town Clerk, in dealing with the application, said that in August, 1893, a Local Government Board enquiry was held into an application to borrow £40,000 for the purposes of the installation. At that time evidence was given showing how that money was proposed to be expended, and it was intimated that for the present they would only spend £22,700. As the result of the enquiry, the Local Government Board gave their sanction for the borrowing of £22,700, and reserved their consideration as to the rest of the £40,000 for any future time when the Council were prepared to proceed with the expenditure. The works had been completed, and the supply of current commenced in October last. They had been fairly successful with the undertaking. They had paid their way with the exception of the amount required for the repayment of loans, and that was considered a very fair and satisfactory position for a beginning. Numerous applications were being received for further service in different parts of the town where mains had not been laid, and the Council had come to the conclusion that it was desirable to complete the original scheme, and ask for the remainder of the £40,000. There had been actually spent already more than the £22,700, the extra cost being due to the building. Mr. Murphy gave evidence respecting the works and the cause of the original estimate being exceeded by over £3,000. Great difficulties were also experienced with the foundations. In answer to the inspector, Mr. Rider said the building had been completed for £10,400. The works were sufficient for all estimated purposes. The Inspector pointed out that if £40,000 was originally estimated as the cost of the undertaking, and there had already been an excess of £3,100, it was likely the Corporation might need £43,000. Hadn't the Council at the next meeting better pass a resolution and rectify the application so that there would not have to be a second enquiry? The Town Clerk replied that the Council resolved to apply for the remainder of the £40,000 originally sanctioned, but consideration would be given to the suggestion of the inspector. Mr. Rider said more than £40,000 would be ultimately required. The amount put down in the estimate would not fill the building with boilers, engines, and alternators. There would still be room for more plant. He thought the estimate of £10,250 would meet the cost of the laying of mains for the next 10 years. Roughly speaking, he thought a further sum of £5,000 would be needed. Mr. Alderman Miles observed that the committee considered it advisable to complete the scheme, as the further works were necessary to meet the public requirements. The Inspector: What do you think about the financial success of the undertaking? Will it contribute to the capital outlay? Mr. Alderman Miles: I have no doubt about it. It is difficult to say when the time will arrive, but I believe that in two or three years, or probably less if the requirement is as great as we expect, the undertaking will be a decided success. We have started so well, and I think we may reasonably anticipate much success. The Inspector: I suppose the tradesmen generally are going in for taking it? Alderman Miles: Yes: there is a big demand. In reply to a further question, the Alderman said the Town Hall-square only of the public thoroughfares was lighted by electricity. It was proposed to extend this system of lighting somewhat. There were six or eight large centres, principally at the junction of streets, where electric lamps would probably soon be fixed, but street-lighting generally by electricity was hardly to be expected yet. Mr. Rider asked if the time for the repayment of the loan could not be extended beyond the usual term of 25 years, but the inspector, while promising to enter the matter in his report, held out little hope of any extension. There was no opposition to the application, and the enquiry into the matter closed.

Yarmouth.—Colonel J. O. Hasted, R.E., representing the Local Government Board, held a public enquiry on Thursday last week relative to the application by the Town Council for leave to borrow a further sum of £17,500 for electric lighting. Among those present were Messrs. J. W. Cockrill (borough surveyor), A. H. Preece (for his father, the consulting electrician to the Corporation), W. Vincent (chief assistant to the surveyor), and H. Ranken (electrical engineer in charge of the local station). The borough surveyor explained that the first loan for the electric light was for £15,000, and this was followed by another of £1 500 to make good the deficiencies in the first estimate. Of the present application, £2,000 was for connecting up 150 customers and £15,500 was for extensions to plant. The electric light was started on January 12 last for the supplying of private customers, of whom there were 87. Of these, 75 were connected up and had 4,534 lamps. The power of the existing plant was equal to 4,500 lamps for private lighting, and this was according to the original estimate. Mr. A. H. Preece said that the plant was working up to its maximum capacity, and it was absolutely necessary to increase it. £1,600 was to be spent in buildings, £1,200 for boilers, £4,800 for four steam dynamos, £3 000 for mains, £1,500 for transformers and transforming stations, £250 for switch boards, £2,000 for connecting customers and meters (250 at £8 each), and £1,000 for contingencies. The new estimate was to provide for 9,000 lamps to be alight at one time, and would enable the Corporation to deal with a demand for 14,000 or 15,000 lamps connected with the mains, because the lamps were never all alight at one time. No more arc lighting was to be provided, as no revenue was to be obtained from it. The cost of lighting by gas was less. The cost of 52 arc lamps was £750, and the gas turned off only cost £600. Mr. Peaton asked whether if the Council decided upon a further extension of street lighting new machinery must be laid down, or the existing machinery displaced and other plant substituted. Mr. Preece replied that any additional arc lighting would mean the addition of machinery. The intention was to add the proposed plant as the demand increased. It was intended to lay down two more main cables in the town. At present there were two, one along the parade and the other along the centre of the town through King-street. These had proved too small. They would lay mains along the South-quay into the centre of the town and along Nelson-road, which would supply the customers obtained in those districts. The mains were laid in quadruplicate, two for public and two for private lighting. The Council were going to lay three miles of high-tension cables and two miles of low-tension cables. The houses had in the past been fitted with small transformers, but now it was proposed to group them, and put in a large transformer to each group. These would be erected in underground chambers in the streets. They were gas-tight, and there was no danger. Mr. J. H. Palmer asked whether the transformer stations could not be placed in the road rather than in the pavement in case of there being any danger. There were, he said, constant complaints of the obstruction caused while the workmen were "performing" below, particularly in King-street. The Surveyor replied that in future he would not place any of the stations in thoroughfares. The Inspector asked how much was required immediately. Mr. Preece replied about £1,600. Next winter they hoped to have the

Digitized by Google

plant working night and day. The Surveyor stated that the street-lighting cost £770 per annum, and 4,300 lamps nightly meant a revenue of £2,250 from private consumers, while the annual expenditure at the station was £1,600; £760 was received from the Sanitary Authority for the street-lighting, and the light in the Beach Gardens, where oil lamps were formerly used, cost £60 per year. Mr. Preece calculated that repayment of capital and interest now amounted to about £900 a year. The Inspector said that would bring up the total expenses to about £2,600 a year. Mr. Preece: The present income will just clear that. Mr. J. Rogers asked whether the services of the consulting engineer were to be retained, as he was so expensive. The Inspector said this did not come before him. It was a matter for the Town Council. The Surveyor said that on Wednesday applications were received from three customers for 250 lights. The Inspector: How long will the present loans keep the Council going? The Surveyor: Two and a half years. The Inspector: Then you would have to come for further loans? The Surveyor: Yes, but every extension for private consumers would mean fresh profit. The Inspector said that he was satisfied with the evidence. He then proceeded to inspect the plant at the generating station.

PROVISIONAL PATENTS, 1895.

JUNE 1.

10875. **Improvements in means of lighting cigars, cigarettes, and pipes by electricity.** James White Collings and William Friese-Greene, 41, High-street, Weston-super-Mare.

10895. **An improved electric light standard for workshops and the like.** George Stegmann, 41, Meyrick-road, Clapham Junction, London.

10903. **Improvements in or relating to automatic safety devices for electric currents.** James Barns Stone and Samuel Barnes, 323, High Holborn, London.

10929. **Improvements in apparatus for electrolysing chloride solutions.** Eugene Hermite, Edward James Paterson, and Charles Friend Cooper, 28, Southampton-buildings, Chancery-lane, London. (Complete specification.)

18930. **Improvements in apparatus for electrolysing chloride solutions.** Eugene Hermite, Edward James Paterson, and Charles Friend Cooper, 28, Southampton-buildings, Chancery-lane, London. (Complete specification.)

10951. **Improvements in secondary batteries.** Edwin Freund, 2, Lancaster-place, Strand, London.

JUNE 4.

10977. **Improvements in holdfasts for lightning conductors.** Frank H. Starling, Gresham Electrical Works, Nottingham.

11014. **Improvements in electric governors.** Joseph William Myers, 106, Priory-park-road, Kilburn, London.

11016. **Improvements in electrolytic decompositions, and especially in the electrolytic production of bleaching agents and their uses, and in electrodes and apparatus therefor.** Henry Blackman, 55, Chancery-lane, London. (Complete specification.)

11025. **Improvements in apparatus for working railway switches and signals by means of electrical energy.** Siemens Bros. and Co., Limited, 28, Southampton-buildings, Chancery-lane, London. (Messrs. Siemens and Halske, Germany.)

11032. **Improvements in secondary batteries or accumulators.** Theodor Eremin, 45, Southampton-buildings, Chancery-lane, London.

11035. **Improvements in electrical signal or time-alarm clocks.** Herman Zeidler, 45, Southampton-buildings, Chancery-lane, London.

JUNE 5.

11085. **Improvements in arc lamps.** Joseph Devonport Finney Andrews, 45, Fulham-park-gardens, Fulham, London.

JUNE 6.

11110. **Improvements in and relating to electric arc lamps.** William Fox and Frederick Samuel Burroughs, 1, Oriel-street, Lower Broughton, Salford.

11153. **Improvements in motor-generator transformers.** Alexander Bewicke Blackburn and Wilfrid L. Spence, 47, Lincoln's-inn-fields, London.

11180. **Improvements in means for protecting pipes, electric cables, and the like laid in the ground.** Henry Edmunds, 47, Lincoln's-inn-fields, London.

11181. **Improvements in switching apparatus for electric circuits.** Henry Edmunds, 47, Lincoln's-inn-fields, London.

JUNE 7.

11222. **Improvements in voltaic batteries.** Desmond Gerald Fitz-Gerald, 53, Chancery-lane, London.

11227. **Improvements in the arrangements for starting alternate-current electromotors.** Galileo Ferraris and Riccardo Arnó, 45, Southampton-buildings, Chancery-lane, London.

11235. **Improvements in electric fire-alarm apparatus.** Edward Jonathan Dale, 4, South-street, Finsbury, London.

JUNE 8.

11266. **Improvements in electric light ceiling roses.** Joseph Devonport Finney Andrews and Edward Jesse Piper, 34, Victoria-street, Westminster.

11279. **Improvements in or connected with locomotives, also applicable to tramcars, electric cars, carriages, and other vehicles.** Ellis Lever, 6, Lord-street, Liverpool.

11283. **Improvements in and relating to electric high and low tension fuse-heads for use in blasting and other purposes.** George Pettinger, 54, Fleet-street, London. (Complete specification.)

11297. **Improvements in or relating to incandescent electric lamps with two or more filaments.** Albert Zobel, 18, Buckingham-street, Strand, London.

11298 **An improved method or process for obtaining metals or metallic alloys by electrolysis.** Edward Jordis, 18, Buckingham-street, Strand, London.

SPECIFICATIONS PUBLISHED.

NOTES.

Personal.—The Académie des Sciences have elected Mr. Newcomb, of Washington, as a foreign associate, in the room of the late Prof. Helmholtz.

A New Insulating Material—Ambroin.—Ambroin has been invented by Herr F. G. Kleinsteuber, of Bavaria, as a substitute for indiarubber, celluloid, horn, ebony, etc. It is manufactured in various colours and in different brands.

Light Railways.—Sir E. Grey informed Mr. Dodd in the House of Commons on Tuesday that information in regard to State aid granted in foreign countries to light railways had been obtained, and would shortly be laid before Parliament.

Proposed Belgrade-Budapest Telephone.—The Servian Ministry of Trade has decided to enter into negotiations with the Hungarian Government with the view of establishing direct telephonic communication between Belgrade and Budapest.

Projected Brussels-The Hague Telephone.—It is announced that the Belgian and Dutch Governments have concluded a convention according to which telephonic communication is to be immediately established between their respective capitals.

Electricity at the Bordeaux Exhibition.—A correspondent of *L'Electricien* complains that of all the sections at the Bordeaux Exhibition that of electricity is farthest removed from completion, and he advises people not to visit the show before July.

Physical Society.—At the meeting to be held on 28th inst. papers will be read on (1) "An Electromagnetic Effect," by Mr. F. W. Bowden; on (2) "Synchronous Motors," by Mr. W. G. Rhodes; and on (3) "The Electrical Properties of Selenium," by Mr. Shelford Bidwell, F.R.S.

The Stuttgart Exhibition, 1896.—Two hundred and ninety-one firms have up to the present announced their intention to take part in the electrotechnical and art industrial exhibition which is to be held in Stuttgart next year, of which number, 157 will make a show in the electric motor section.

Royal Society.—Among the papers read at yesterday's meeting of the society were "The Magnetical Results of the Voyage of H.M.S. 'Penguin,' 1890 93," by Captain Creak, F.R.S.; and "A Dynamical Theory of the Electric and Luminiferous Medium—Part II. Theory of Electrons,' by Prof. J. Larmor, F.R.S.

Telephones at the Baltic Canal Festivities.—Following the example we set in the Spithead roadstead, the German Admiralty made arrangements for establishing telephonic communication between the shore and the German and foreign flagships and Royal yachts on the occasion of the opening of the Baltic Canal.

Society of Arts.—The annual conversazione of this society was held in the South Kensington Museum on Wednesday evening, and a very large number of members and visitors attended. They were received by Sir John Donelly, the chairman of the council, Sir C. W. Kennedy and Sir Westby Percival, members of the council.

Electric Light in a Convent.—The Brothers of Mercy of Trier (Trèves), of Sacred Coat fame, are anxious to have their domicile illuminated by about 350 incandescent lamps and two arc lamps. An engine, they announce, is already on the premises Three synagogues in Frankfort-on-Main are, by the way, being fitted with the electric light.

At Last.—It is now definitely announced that the Berlin municipal authorities have concluded an agreement with Messrs. Siemens and Halske, according to which this firm is to construct an electric overhead railway in the Prussian metropolis. This information reaches us simultaneously with the announcement that the Milan municipal authorities have granted a concession to the Edison Company, in that city, for the conversion of horse-traction tramways into electric lines.

Telegraphy in Warfare.—The Telegraph Department is the one that has best succeeded in distinguishing itself in recent war business, Chitral way, says *Indian Engineering*. The field telegraph has always been kept well in touch with the fighting column. Men who understand something about frontier fighting know that this result represents a large amount of prevision, pluck, and endurance. The latest news from the front in this connection is that a field telegraph office was opened at Ziarat, over the Lowari Pass, on May 5, and one at Ashreth on the 6th.

Water Power in Northern Italy.—Three schemes for utilising water power for electrical purposes are at present under consideration in Northern Italy. The first proposes to turn to account the Toce River, whence it is estimated 18,000 e.h.p. could be obtained for use in Milan, Gallarate, Busto, Castellanze, and Legnano; the second aims at appropriating, for application in Turin and district, the water power of the Cenischia Valley, near Susa, to the extent of 10,000 e.h.p.; while according to the third scheme 3,000 e.h.p. would be procured from the Gressoni Valley, near Biello.

Books Received.—The Electrical Company, Limited, 122, Charing Cross-road, send us "Electrical Transmission and Distribution of Power," a work based upon the results of undertakings carried out by them and their affiliated firms. The book is published by the company. We are in receipt of the July number of the *English Illustrated Magazine*, which maintains its high standard. Also of "Armature Windings of Electric Machines," by Messrs. H. F. Parshall and H. M. Hobart; the publishers are the D'Van Nostrand Company, New York, and Mr. Robert W. Blackwell, 39, Victoria-street, Westminster.

Municipal Engineers.—The annual meeting of the Incorporated Association of Municipal and County Engineers will be held at Halifax on Thursday, Friday, and Saturday, 27th, 28th, and 29th inst.; president, Mr. Edward Rice Sweet Escott, M.I.C.E., borough engineer, Halifax. The members will assemble on Thursday, 27th inst., in the Town Hall. On the Friday a visit will be paid to inspect the gasworks and electricity works under the guidance of Mr. Alderman Brook and Mr. Alderman Robinson, the chairman and vice-chairman of the committee, together with Mr. T. Holgate, the gasworks engineer, Mr. T. P. Wilmhurst, the electrical engineer, and Mr. W. H. D. Horsfall, the architect of the electricity station.

Electric Lamps for Policemen.—At a meeting of the Watching, Lighting, and Fires Committee of Aberdeen Town Council, Bailie Mearns and the Chief Constable were, on the suggestion of Bailie Scott, instructed to enquire as to the cost of providing the night constables with lanterns electrically lighted, instead of the present oil lamps. The committee unanimously took up the idea in anticipation that not only would electric lanterns prove more effective than those at present in use, but that there would be a saving in the cost of upkeep, etc. The sight of an Aberdonian "bobby," who is about as slow naturally as his London *confrère*, trying to capture a runaway thief while impeded with a heavy accumulator, would be enough to make a cat laugh.

Digitized by Google

Electric Cranes.—The Southampton Harbour Board on Tuesday last resolved to erect three additional electric cranes, and also to have their own central station instead of taking current from the town. Mr. Aldridge, of 9, Victoria-street, Westminster, was instructed to prepare the necessary plans and specifications for the cranes and station. There are already two three-ton electric cranes at work, and the new cranes will probably comprise one twelve-ton and two two-ton cranes on overhead gantries. Up till now the current has been supplied by the local company at 6d. per unit, and the Board hope to effect a considerable saving by putting down their own plant. This station will supply current for the pier and quay lighting, and for the five cranes when completed.

London Chamber of Commerce.—An extraordinary general meeting of the members of the London Chamber of Commerce will be held in the council-room, Botolph House, Eastcheap, to-day (Friday), at 2.30 p.m., when the subjoined resolution, which was passed at an extraordinary general meeting of the Chamber held on May 21 last, will be submitted for confirmation as a special resolution: "That the articles of association be altered by the addition to Article 22 of the following clause, to be distinguished as Article 22A: 'The council may admit to honorary membership of the Chamber persons distinguished in statesmanship, diplomacy, commerce, or finance, who shall not be required to sign the application mentioned in Article 19 of the articles of association of the Chamber, or to pay any subscription.'"

Boiler Explosions.—In reply to Mr. Holland in the House of Commons on Tuesday, Mr. Bryce said he had no certain information as to the number of boilers in use in the United Kingdom, but assuming it to be between 150,000 and 200,000, the proportion of explosions was now as it was in 1871—about 1 in 2,000 per annum. In 1871 the Select Committee on boiler explosions reported against the introduction of any system of compulsory inspection, one of their reasons being that a great number of the explosions arose from causes independent of and apart from anything that could be prevented by periodical inspection. Having regard to this opinion expressed by the committee, and to the enormous magnitude of the task which would be thrown upon the State were it to undertake the duty of periodically inspecting all boilers, much consideration would be needed before introducing such a Bill as Mr. Holland appeared to contemplate.

The Pacific Cable.—A meeting was held on the 9th ult., at Sydney, in the Chamber of Commerce, in support of the proposal to establish a cable *vid* the Pacific, Mr. W. Friend presiding. There were also present Messrs. J. S. Larke (Canadian commissioner), A. L. Jessop (president, Adelaide Chamber), D. J. M'Lean (Newcastle Chamber), and others. Mr. S. A. Joseph moved the first resolution, as follows: "That this meeting is of opinion that, in the broadest interests of the British Empire, the early establishment of a cable, connecting Australasia and Canada, across the Pacific, and under British control, is a necessity." Mr. J. H. Storey seconded the resolution, which was supported by Mr. Larke, the last-named giving particulars of the scheme. The resolution was carried unanimously, as also was another approving the scheme and urging upon the Government of New South Wales the advisability of communicating with the Imperial Government and the Governments of Canada and Australasia with the object of having an early and searching investigation into its practicability and advantages.

Tramways Institute.—The annual general meeting of the Tramways Institute of Great Britain and Ireland will be held at the Holborn Restaurant, High Holborn, London, on Thursday, 27th inst., at 11 a.m., for the transaction of special and other business as under: (1) adoption of report and accounts for the past year; (2) election of president; (3) election of vice-presidents and executive committee; (4) election of auditors; (5) appointment of quarterly meetings for session 1895-6; (6) reading of papers on the undermentioned subjects and discussion thereon: (*a*) discussion on "Traction Up to Date," with special reference to report to Newcastle Town Council, by Mr. W. G. Laws, M.I.C.E., city engineer; (*b*) "Traction and Lighting by the International Electric Storage Accumulators," by Mr. A. G. New; (*c*) Thwaites and Cawley's System of Electric Haulage," by Mr. George Cawley, M.I.M.E.; (*d*) "Mattison's Hydraulic Brake." Annual dinner at the Holborn Restaurant, at 7 p.m. On Friday, 28th inst., a visit will be paid to the Exhibition of Railway Appliances and Inventions at the Imperial Institute.

A Franco-Egyptian Scheme.—Parisian papers contain particulars of a grandiloquent scheme, mooted by a French engineer, M. Prompt, which proposes to utilise the waters of the Nile with a twofold object—irrigation and the production of motive power. In the first place, M. Prompt would substitute the cultivation of cotton and sugar cane for the growth of cereals, and establish works for treating these articles of commerce. He would then make use of the cataracts of the great river, as the Falls of Niagara have partially been turned to account, for the distribution of electrical energy. A reservoir, to be built at Assouan, to contain 500 million cubic metres of water, would serve for irrigation purposes, and produce at the same time, he avers, a force of 40,000 h.p., which would be used to run 130 cotton-mills, furnishing employment to 40,000 workers, and consuming every year 100,000 tons of cotton, or about half of the production of the country. About 430,000 tons of sugar could, moreover, he estimates, be annually obtained from the additional watered land. And M. Prompt would guarantee to carry out his brilliant idea at a total cost of 40,000,000f., or £1,600,000, which would be made to yield a net yearly revenue of 10 per cent.

German Electro-Chemical Society.—The second annual meeting of the Deutsche Elektrochemische Gesellschaft took place on June 6-8. Prof. Ostwald, of Leipzig, who occupied the chair, delivered an address on "The Seat of E.M.F." He said that modern work—for example, the investigations of Helmholtz, as distinct from the theories of Galvani, Volta, and their successors—showed that electric energy emanated from the chemical process involved in the contact of metals and acids. Dr. Pollak, of Frankfort-on-Main, followed with a paper on "The Charging of Accumulators by Means of Alternating Currents" (see *Electrical Engineer*, p. 616). The discourse of Dr. Jordis, of Munich, on "Analysis by Electrolysis," also excited interest. He recommended, instead of oxalic acid, the use of lactic acid and glycolic acid for electrolytic purposes; for chlorides and nitrates, he observed, give as good metallic deposits as sulphates. Prof. Eilhard-Wiedemann, of Erlangen, spoke of "The Chemical and Optical Effects of Cathode Rays"; and Dr. Fölsing, of Niederlahnstein, referred to his "Electrolytic Tanning Process," by which, he claimed, in from three to six days the heaviest skins could be tanned—skins which hitherto, he said, took a year to dress. Dr. v. Kovalski, of Freiburg, Switzerland, next declaimed on his "New Accumulator" for the lighting of trains, etc., which has been tried upon French railways. Dr. Pollak questioned the novelty of the accumulator, and Dr. v. Kovalski defended its originality, giving further particulars concerning the storage battery. Prof. Ihle, of Leipzig, in conclusion, communicated details

Digitized by Google

of some electro-chemical experiments with nitric acid that he had made.

University College of South Wales. — The testing-house, workshop, laboratory, and boiler-house of the engineering department of the University College of South Wales and Monmouthshire have been drawn up on a large scale. The buildings have been designed by Prof. Elliott, the professor of engineering, and the permanent buildings are provided with right-angle roofs, so that a north light is obtained. Messrs. Lattey and Co., Cardiff, were the contractors for the work; Messrs. John William and Sons, Cardiff, being the sub-contractors for the steelwork in the roofs. The boiler is of the water-tube type, and is rated at 76 h.p., but with economical engines it will develop about 150 h.p. It has been supplied by Messrs. Babcock and Wilcox, Limited of Queen Victoria-street, London. The smoke stack is 100ft. high and is constructed of red glazed brick. A high-speed engine, built by Messrs. Willans and Robinson, of Thames Ditton, has been erected in the laboratory, it being the first of four that are required for practical investigations and experiment. It is of 40 h.p., making 527 revolutions a minute and directly driving the dynamos. The smoke-stack is fitted with an elaborate but comparatively inexpensive system of lightning conductors on a principle which is the outcome of the researches of Prof. Oliver Lodge, D.Sc., the conductors being made and erected by Messrs. S. F. Walker and Co., Cardiff. The total cost of the buildings, exclusive of machinery and fittings, electric light installation, etc., has been over £4,000. At the inaugural ceremony on the afternoon of Wednesday last, Mr. T. H. Riches, chairman of the Technical Education Committee, presided.

As Others See Us.— Signor Guido Semenza, an intelligent Italian electrical engineer who recently visited some of our London central stations, has written a really funny account of his experiences while sojourning here. It is so funny that possibly, when they read it, some of the firms who unsuspectingly conducted this *anguis in herbâ* over their works, and gave him full details of their plant, would like to see him again with a different object. To begin with, Sgr. Semenza avers "that England is certainly not one of the nations which are most advanced in electricity." Then he goes on to say that it is especially in regard to the mechanical application of electricity in this country that he has been "disillusioned"—"no novelty, no tendency toward progress." We "use the two-pole dynamo to the almost absolute exclusion of other systems. Multiphase currents have with us only so far made their appearance in the laboratory, and are looked upon much as in other countries navigable balloons are regarded." Our metropolitan central stations are all alike: "a trashy entrance; an obscure alley leading to the back of a pile of buildings; then a covered passage just wide enough to let a coal-cart through; on the left a pile of coal, on the right the boiler-house," etc. Finally, as a parting shot, we are told that "profound observation proves that the conservative English rarely push things to perfection, apparently because they are held back by exigencies antagonistic to progress." But Sgr. Semenza has, after all, a little to say in our favour. He admires the "readiness with which we are abandoning the slow-speed steam-engine and adopting its high-speed rival"; and also our efforts, as "past-masters in steam-engines," to make the dynamo "above all, a simple and strong machine." And we must, we suppose, like Mark Tapley, be thankful for small mercies."

The Shahzada and Electricity.—After having last week inspected the Liverpool Overhead Electric Railway, the Shahzada was so impressed that he made an appointment for the following day to examine the generating station. According to a local paper, the party, which was conducted by Sir W. B. Forwood, Mr. R. Hobson, and Mr. Cottrel, first inspected the boilers. All the explanations were made by Mr. Cottrel, and were interpreted to the Prince by Colonel Talbot. There seemed to be quite an incongruous air about the scene. First, upon looking through the boiler-house entrance, was to be seen the Lord Mayor in his purple robe and cocked hat, standing on some cobbles of coal. Then, down in the basement, right at the very mouths of the boilers, was the Prince and his motley-looking party, most of whom were regarding what they saw with blank astonishment. The most interesting part of the inspection, however, was that made in the generating-house proper. Some of the native suite appeared a trifle timid when they got to close quarters with the moving machinery; but the Shahzada took matters very calmly, and asked innumerable questions, which were answered by Mr. Cottrel through Colonel Talbot. Altogether about half an hour was spent going through these works, and when the inspection was ended, so impressed had the Shahzada become by the wonders of electricity, that he asked Colonel Talbot to inform Mr. Cottrel that he much desired to have some electrical appliances sent over to his home. It is evident from other facts which have come to light that his Highness has at last become fascinated with electricity. He visited the mosque at a late hour on Wednesday, and, after prayer, was taken through the building by Abdullah Quilliam and others. He was conducted to the electrical room, from whence the motive power is supplied for the electric lighting of the building. It was difficult to get him from this place. He tested the small dynamos, and had all kinds of little experiments made, and did not leave the building until eleven o'clock. The local reporter is evidently unaware that there is an electric light station at Cabul.

Mechanical Traction on Roads.—In the House of Commons, on Monday, Mr. Shaw-Lefevre, on rising to ask leave to bring in a Bill to amend the law with respect to the use of locomotives on highways, explained that the Bill only contained one clause, and, was not, he hoped, of a controversial nature. Its object was to exempt carriages propelled by other than horse power from the regulations of the Locomotives Act in cases where they were not used for traction purposes. Hon. members who had recently visited Paris would have observed that there were not an inconsiderable number of carriages propelled by petroleum, gasolene, steam, and in some cases by electricity. In a trial run between Paris and Bordeaux a carriage propelled by petroleum won, having travelled at a rate of 15 miles an hour. These carriages were completely under command, and horses were not frightened by them any more than by the ordinary traffic. The use of these carriages was practically prohibited in this country by the regulations of the Locomotives Act, which was passed with the object of applying mainly to engines used for traction purposes. Under the provisions of that Act, it was necessary that every such locomotive should be in charge of three persons at least—one walking in front, one behind, and one driving—and the engines could not proceed at a greater speed than four miles in the country and two miles in a town, and were also subject to a license of £10 each for every county where they were used. These regulations were totally inapplicable to the light carriages such as he had described as in use in Paris. Under the circumstances, it appeared to him to be reasonable that the House should exempt carriages of that kind from the provisions of the Locomotives Act. They would be subject to the ordinary regulations of other carriages, or to any other regulations that the House might think fit to be made by the Local

Digitized by Google

Government Board. He thought that the regulations should be made by that or some other central authority rather than by some local authority, because the necessity for uniformity was so great that it would not, he thought, be well to make these vehicles liable to different regulations by every county. He had hoped to carry the Bill further, and had been in correspondence with the County Councils Association for this purpose; but that association desired further time to consult the local authorities on the subject. He had, therefore, been compelled to postpone the further scope of the measure and to limit it to the one purpose which he had described. Mr. Jeffreys enquired whether these carriages would pay the usual locomotive tax. Mr. Shaw-Lefevre replied that they would not. It was proposed to exempt them from that tax, but to make them pay in the way that ordinary carriages now pay. Colonel Kenyon-Slaney asked what limit of weight the right hon. gentleman proposed to fix for these vehicles. Mr. Shaw-Lefevre said that he had put a limit of two tons. Leave was then given to bring in the Bill, which was read a first time.

Trunk Telephone Charges.—In connection with the subject of new telephone trunk lines from London, these will constitute a part of the general telephonic organisation of the country, and may be used for short distances as well as long ones. The scale laid down by a Treasury minute is 3d. for a conversation of three minutes for any distance not exceeding 20 miles. Over 20 and under 40 miles the charge will be 6d., and 6d. for every additional 40 miles, or part of 40 miles, the only exception being that a small additional charge may be made where a submarine cable is used or any exceptional expense is incurred. The question has been asked whether the telephones of private subscribers will serve for communications over these long distances by the new trunk lines. The Post Office authorities reply that they will, where the line is a double one; but where there is not a complete metallic circuit, and especially where the distance between the subscriber's instrument and the Post Office wires is considerable, working is not likely to be very satisfactory. In this connection Messrs. D. M. Stephenson and Co., of Leith, write: "The Swedish tariff for distances not exceeding 62 miles is 2d.; not exceeding 155 miles, 4d.; not exceeding 375 miles, 6½d. The Swedish Sound ports, although 400 miles from Stockholm, are included in the 6½d. rate. Stockholm subscribers paying annually less than £5 have a right to speak within a radius of 70 kilometres without extra charge, so that on the same basis there ought to be no trunk fee payable by Edinburgh subscribers for speaking to Glasgow and intermediate places. Will you allow us to complete the list of charges you give for trunk conversations from Edinburgh by putting in parallel columns the rates which would be charged for similar service in Sweden?

	Tariff.	
From Edinburgh to	British.	Swedish.
Glasgow	6d.	nil.
Liverpool	2s. 6d.	6½d.
Cardiff.....	4s.	6½d.
London	4s. 6d.	6½d.
Plymouth	5s. 6d.	1s. 1d.

It must be borne in mind that the Swedish system is of the most perfect description, with twin wires throughout, and the most modern transmitters and receivers. The Swedish Government have no greater facilities than ours in regard to wayleaves, and the Swedish operators are better paid than those in this country. The only justification, therefore, for the enormous extra charges to which we are to be subjected is the excessive price—cost plus 10 per cent. instead of cost minus depreciation—which the Government is paying for the telephone company's white elephant; for it is well known that the company's trunk business has been unprofitable, and has been carried on solely for the sake of the great increase it brought of the very profitable local business. It is true that the Post Office system has been established in terms of a Treasury minute of Lord Salisbury's Government of date May 27, 1892; but the present Government will find it hard to get rid of its responsibility for going on with a scheme which is foredoomed to be financially as disastrous as the telegraphs, unless allowance be made for the facts which have been pressed upon its attention since 1892."

Gas and the Electric Light.—In a paper read before the Incorporated Gas Institute at their Edinburgh meeting last week by Mr. William Newbigging, of Manchester, on "The Transfer of Gas and Water Undertakings to Public Authorities," the author said: "The purchasers of such works are, of course, the public authorities, as representing the ratepayers; and they are, naturally, anxious to pay as small a sum as possible for the undertaking. If it is a water undertaking, there is not as much to pick at as is the case with a gas undertaking; and the state of the works, with a hint or two that the purity of the water is not all that it might be, and that an immediate expenditure is necessary, together with any financial misdoings, are about the sum total of the statements made to depreciate the value of the concern. A gas undertaking has usually to bear the brunt of a much more severe attack. Added to the charges above mentioned, it is pointed out that, since the electric light came more generally into use, it has had the effect of lowering the market value of the shares, and consequently the whole value of the undertaking. Also that the recent improvements made in oil lamps and the greater cheapness of oil have made this a more formidable rival than before; that from the facts of the profits depending, to a great extent, on the price of coal, and that in recent years the price of labour has increased, the profits are not likely to be as much in the future as in the past. Such, as a rule, are the arguments used to depreciate the value of the undertaking; and it is necessary to refute them. Has the electric light in any single instance been detrimental to the interests of a gas company? On the contrary, it has stimulated the gas companies to greater efforts; and they have increased their consumption in directions which at one time were hardly dreamt of. I refer more particularly to the increased consumption of gas in the daytime—to the hundred and one purposes to which gas is applied, and where it may now be said to be indispensable. No; the electric light may in some instances have caused the market price of the shares to droop a little, but it has in no way altered the real, substantial value of a well-managed gas concern. The recent improvements in oil lamps (and they were much needed) are to be commended; but the advantage that oil possessed—in that people were able to pay for it as they used it—has been counterbalanced by the introduction of prepayment meters. The enormous demand for these is a proof that people prefer gas to oil if they can pay for it by small instalments. So much for oil. As regards the price of coal and the labour question, these are factors which influence the success of every undertaking, whether railway, gas, or electric light. All these statements are brought forward with a view to reducing the value. A concern burdened with a heavy capital on which maximum dividends are being paid is not able to sell gas or water as cheaply as one with a small capital; and it is the possibility of being in a position to lower the price, amongst other reasons, that tempts a public authority to take steps to acquire such an undertaking. They know that the cheapness of these neces-

Digitized by Google

saries—gas and water—is an aid to the prosperity of the town, as it induces people to come to the neighbourhood, not only to reside, but to establish various works where the cheapness of gas and water is a *sine qua non*."

A Unit of Sound.—Mr. Hiram S. Maxim suggests that a standard of sound should be set up. He says: "During the last 20 years many electrical units have been established, and have now gone into common use. For many years we have had units relating to every sort of engineering and scientific question except a unit of sound, and I would like to suggest that some clever experimenter like Prof. Crookes or Prof. Boys should take the matter in hand and establish a convenient unit of sound which would be accepted by the Royal Society of Great Britain and the Board of Trade. If such a unit could be established and accepted by these two bodies, I have no doubt that it would be accepted in the law courts, and might be a ready means of deciding many vexed questions. All owners of electrical plant are liable to be complained of for making a noise. Sometimes it is said that their machinery causes vibrations to the surrounding buildings or grounds; then again that they disturb telephonic communications. Manufacturers are constantly having injunctions served on them for making too much noise when, perhaps, as a matter of fact, the noise is not even audible to those who make the complaint. In many cases, when electrical engineers and those interested in electrical plants have visited the houses of parties who have lodged complaints against electric light stations, it has often been found that the parties making these complaints were willing to swear themselves and to bring any number of witnesses to prove that the noise and jar produced were enough to drive them nearly mad, when, as a matter of fact, the jar and noise were wholly occasioned by the ordinary street traffic, and at the very moment when they pretended to be so much annoyed the electric light plant has not been running at all. Owners of electric and other plant may be, and often are, served with injunctions restraining them from running their works, when in fact the noise complained of is less than that produced by one cab passing along the street. I would suggest, as a starter, that a kind of phonograph should be employed, and that a record should be made on smoked glass which could be put in a magic lantern and greatly enlarged. The amplitude and frequency of the waves would indicate the intensity of the noise produced. For example, suppose a certain record should be made of the noise of the ordinary street traffic, and then another record of the noise of both the street traffic and the disturbance or noise complained of, the two mounted side by side and projected on a large screen would enable the judge to see at a glance how much the noise was increased by the machinery and how much cause there was for complaint, or the noise produced by a factory might be compared with the noise produced by a Salvation Army band, or with other disagreeable sounds which are tolerated by law, at the same distance. As a standard of noise which might be shown in court, I would suggest that shot of a certain size should be dropped, say, from a height of one metre on to some standardised diaphragm, and that the waves should be recorded at, say, five metres from the diaphragm. A record of this artificial noise could be also shown on the screen and at the same time the actual noise recorded produced in court. For telephones, a record of the vibrations set up while the machines were running should be compared with one of those set up when the machines were not running. The comparison of the two would enable the judge—or jury for that matter—to see exactly what the increase in noise actually was."

Society of Engineers.—On the 12th inst. a visit was paid by the Society of Engineers to the Waterloo and City Railway Works, and to the new City of London Brewery. The society have issued the following account of the Waterloo and City Railway: The object of this new electric line is to enable passengers between the London and South-Western Terminus and Waterloo to reach the very heart of the Metropolis with greater ease than is possible with the existing facilities. By this new line passengers will be able to get from Waterloo to a point near the Mansion House, without stoppages, in about four minutes, at an average speed of about 22 miles an hour. To this must be added the time occupied in passing from the South-Western arrival platforms to the subterranean terminus, and from the City terminus to the surface. The departure platform of the electric railway at Waterloo will be about 36ft. below the South-Western platforms, while in the City the depth below the surface will be 65ft. At the latter place lifts will be required, but at Waterloo it is proposed to have easy inclines, with a few stairs at intervals. The line commences at Waterloo at right angles to the existing lines on the southern side of James-street, in the parish of St. Mary, Lambeth, abutting on the Lower-marsh, and, passing under Waterloo Station, curves round to the right, under Cross-street and the South-Eastern Railway viaduct, when it enters the York-road, and still curving to the right, passes under Stamford-street until Hatfield-street is reached. Here it bends to the left on a five-chain curve, and passing under some property at a depth of 56ft. reaches the Surrey side of the river at a point some 500ft. on the up-stream side of Blackfriars Bridge. The river is crossed obliquely, the centre line on the Middlesex side being about 120ft. on the up-stream side of Blackfriars Bridge. From this point the railway bends on a nine-chain curve to the right, and then passes along the centre of Queen Victoria-street to its terminus in the City—opposite the civic residence of the Lord Mayor. The total length of the line will be 1 mile 4 furlongs 6·8 chains, or, in round figures, 1½ miles. From near Hatfield-street to the City both the tunnels will be in the London clay, but from that point towards Waterloo ballast will be encountered. This latter portion of the line will be constructed under compressed air, as large volumes of water will be met with in the ballast. The contract for the construction of the line from Cross-street to the City terminus was let to Messrs. Mowlem and Co. early in June, 1894, and they at once began operations by constructing the stage now so conspicuous an object in the river near Blackfriars Bridge. Here two cast-iron cylindrical shafts were sunk to a point 40ft. below Thames high-water mark, one above each of the tunnels, and below this the shafts were continued by underpinning in brickwork. The shields were then lowered in pieces, put together, and driven forward. Already 1,600ft. of the up, or westernmost tunnel, and 1,400ft. of the down, or easternmost tunnel, have been completed. Both tunnels are now under the Victoria-embankment, and are approaching the Metropolitan District Railway, under which there is a considerable depth of ballast and a small cover of clay over the new tunnels. The Metropolitan District Railway Company required this company to drive the tunnels when passing under, and within 30 yards of their railway, under compressed air, and this is now in progress. The down tunnel towards Waterloo is approaching water-bearing strata, and here also the work is being carried on under compressed air. The haulage of materials to and from the shafts is done by electric locomotives (one in each tunnel), designed and constructed by Messrs. Siemens and Co. The engines and dynamos for the electric lighting of the tunnels have been designed and constructed by Messrs. Paterson and Cooper, of Westminster.

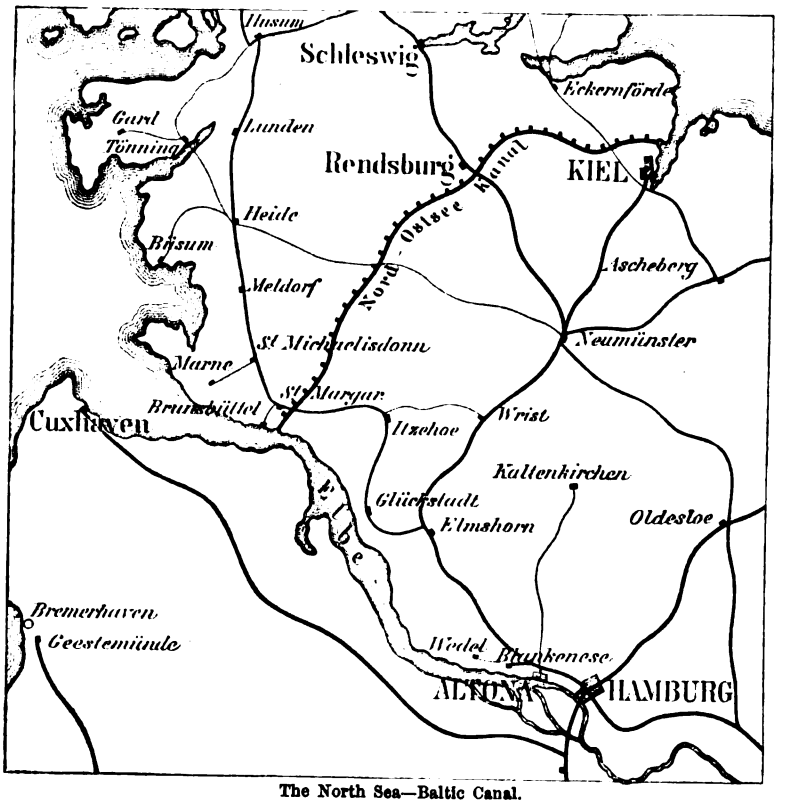
THE ELECTRIC LIGHTING OF THE BALTIC CANAL.

BY HERR C. COERPER, MANAGER OF THE HELIOS COMPANY, COLOGNE.

An undertaking like that of the electric lighting of the Baltic Canal, which is 60 miles in length, has hitherto never been experienced in the electrical industry. True, current has been transmitted to distant points in order to be utilised there for power and lighting purposes—as in the power transmission plant from the River Anio at Tivoli to Rome, a distance of 17 miles, carried out in 1892 by Messrs. Ganz and Co.—but the difficulties have been nothing nearly so great as in the lighting of the whole length of the Baltic Canal. It is easy to take current to a single point and regulate it, but it is difficult to work a large number of lamps placed at considerable distances from each other so that safety and economy may be obtained.



The North Sea—Baltic Canal.

The principles laid down for the scheme, which comprised not only the lighting of the canal but of the locks, harbours, buildings, and harbour lighthouses, were, as has already been stated in the *Electrical Engineer*, as follow: (1) two central stations were to be established, one at Holtenau and one at Brunsbüttel; (2) the stations were to be supplied with the safest economical machinery and apparatus, with an ample reserve; (3) the tension of the current in both stations was to be kept constant whatever the change in the load might be; (4) each lamp was to be independent from the others, so that in the event of a large number of lamps being extinguished there should be no effect on those which remained lighted.

These stipulations have been carried out by the provision at both ends of the canal, at Holtenau and Brünsbuttel, of central machinery-houses for the hydraulic plant operating the locks. Here a large steam supply was installed, which is also available for electric lighting purposes. In the neighbourhood of these the electric generators have been installed.

At each station there are two slow-speed steam-dynamos, made by the Helios Company, of a type which has been largely employed since 1886. The engines run at 85 revolutions per minute, and are each of 200 effective horse-power. The engines are of the horizontal tandem type, with governors by the Maschinenfabrik Augsburg. The cylinders have respectively a diameter of 17in. and 24·5in. and 40in. stroke. At Holtenau surface condensation is proposed, and in the meantime the engines can be connected, if required, with the central condensation plant of the hydraulic station.

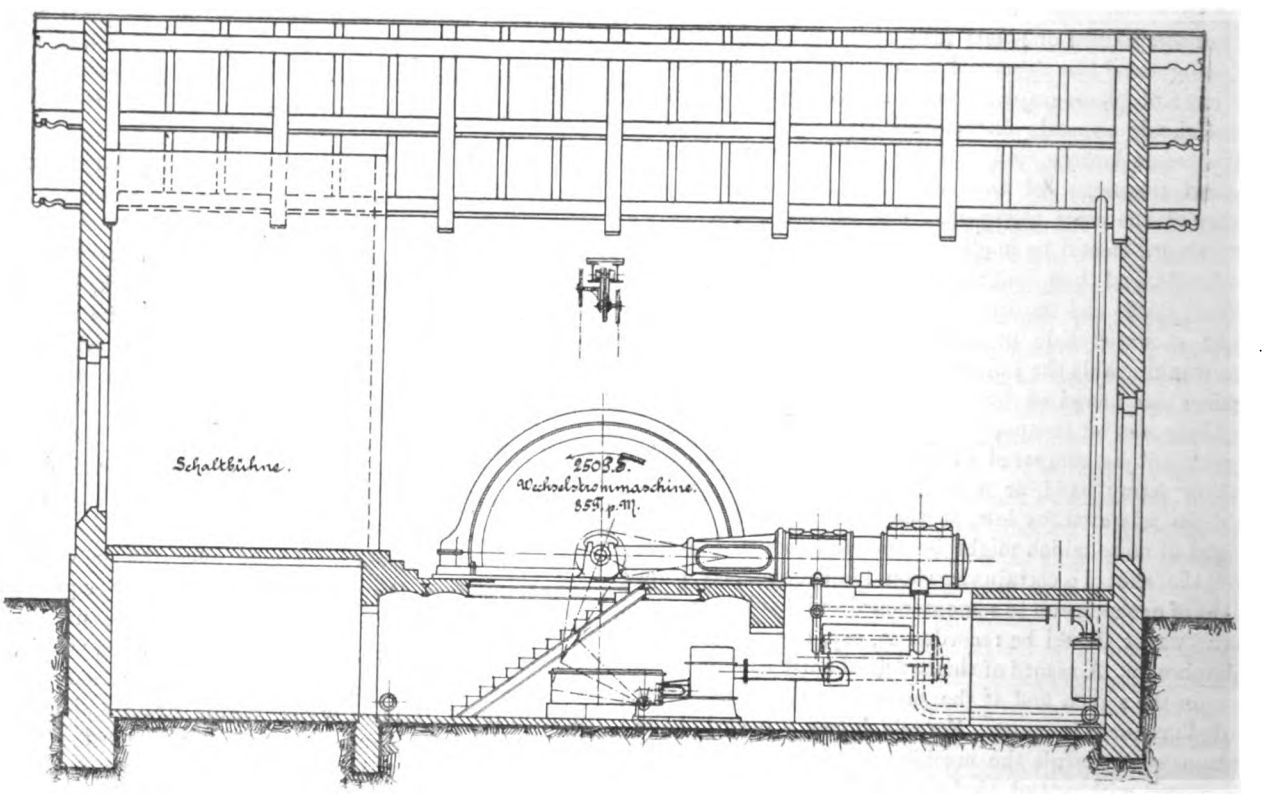


FIG. 1.

Between the two bearings of the steam-engine an alternating-current dynamo is fitted on the shaft, the magnetic field being in one with the flywheel, while the armature ring rests on the beam connecting the two bearings. The

Digitized by Google

ring of the flywheel is turned out to receive the 72 magnets made of 20-mil plates. Care has been taken that the formerly-employed ⊥ shape has been dispensed with. The iron has been widened over the bobbins so that

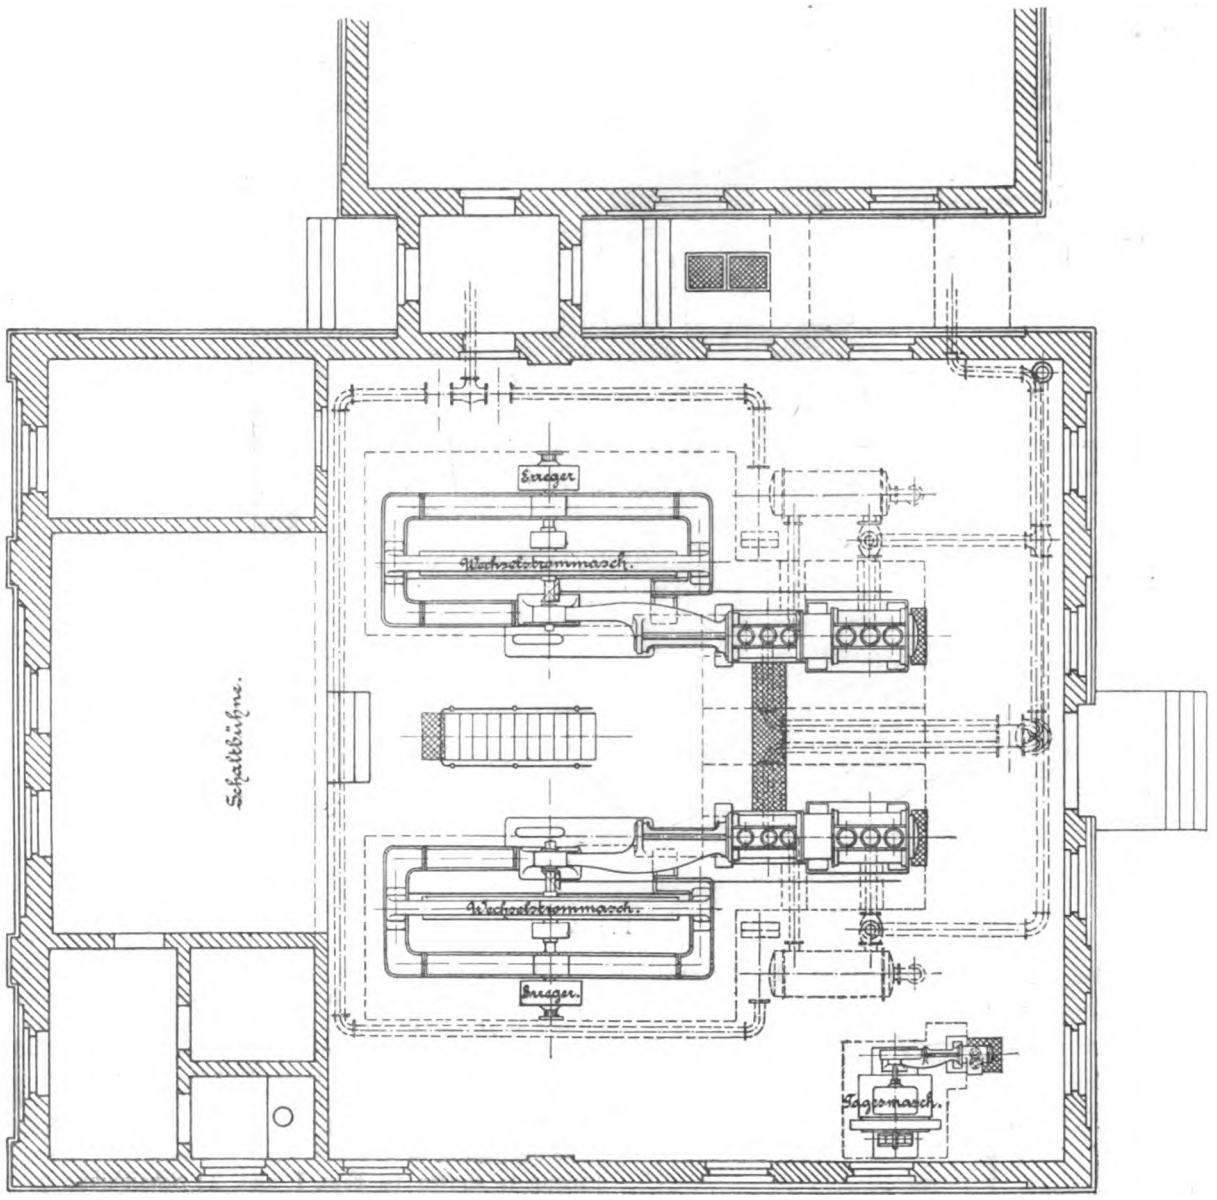

FIG. 2.

that the magnetic circuit is as perfect as possible. The circumferential speed at the surface of the magnets is 2,560ft. per minute, and the frequency of the machine is 51. The armature ring is not only divided on the level of the shaft, so that the upper portion can be lifted off, but the whole ring can be pushed so far sideways that the magnetic field and the armature coils are accessible. In addition, the armature coils are so arranged that they can be drawn out sideways with the armature core by unscrewing four bolts. In Fig. 3 (for which, with the other illustrations, we are indebted to Herr Coerper) is shown an armature segment. It will be seen

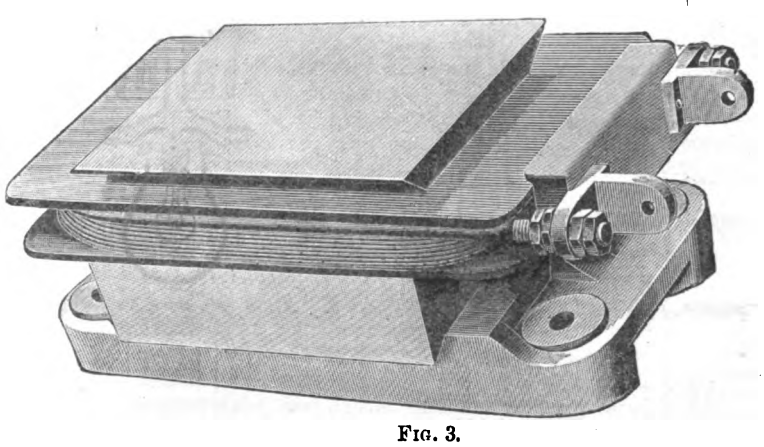

FIG. 3.

segments placed together offer a surface to the magnetic influence only broken by small spaces. The first of this type was supplied by the Helios Company in 1889 for Amsterdam. Experience has shown that with correct measurements a very considerable improvement in the

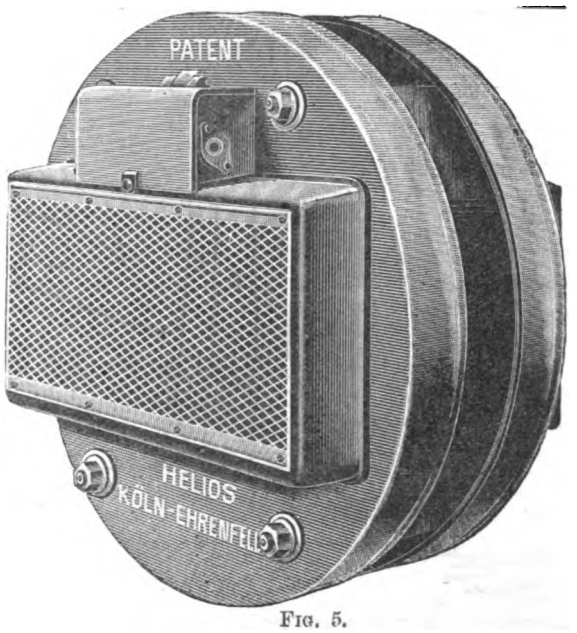

FIG. 5.

Digitized by Google

machines has been obtained, without the disadvantages associated with the so-called tunnelled armature. The

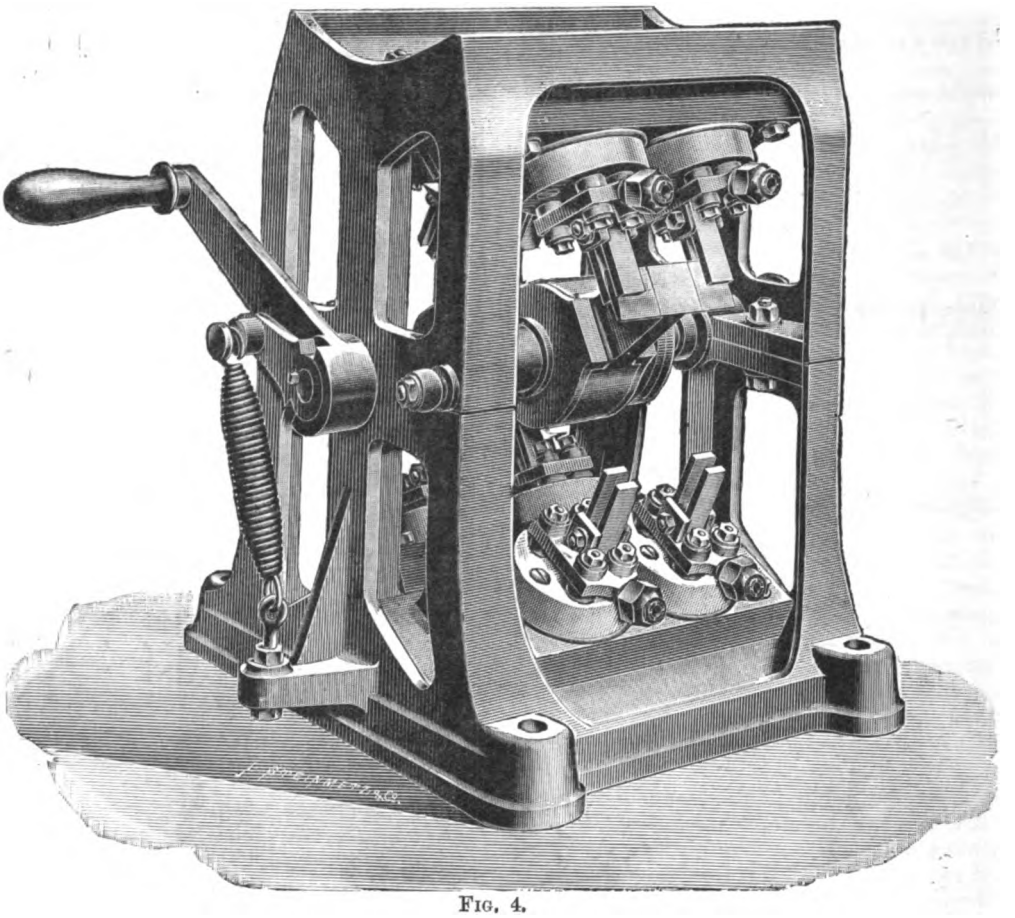

FIG. 4.

pressure of the alternating current at the terminals is 2,000 volts.

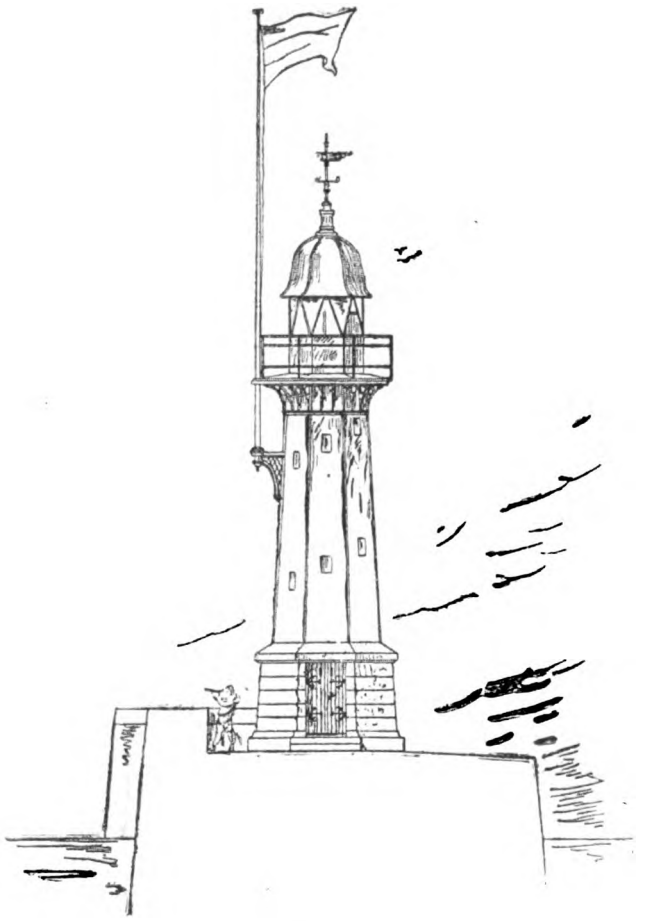

FIG. 7.

As exciter, a four-pole dynamo on the free end of the shaft is employed. The pressure is 120 to 150 volts. The field of the exciter is automatically regulated by a Tesla motor without commutator or collector.

The steam dynamos generate one kilowatt per 12·5 kilogrammes of steam per hour. One steam dynamo is sufficient both at Holtenau and Brunsbüttel for full load, the second forming a complete reserve. At Brunsbüttel an additional small steam dynamo of from 10 h.p. to 12 h.p. is used for lighting the lock chambers during the daytime. It runs at 150 revolutions, and can also be used as a reserve for the excitation of the alternator. The arrangement of the plant is shown in Figs. 1 and 2; *Schaltbühne* being the switching stage, *Wechselstrommaschine* the alternator, *Erreger* the exciting dynamo, and *Tagesmaschine* the day dynamo. The steam-engine at Brunsbüttel has a cylinder

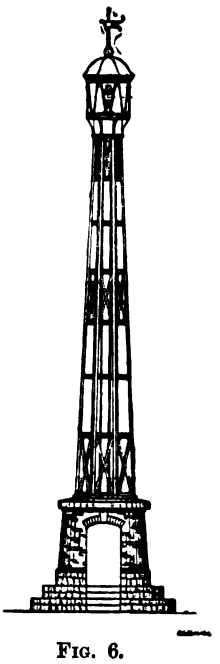

FIG. 6.

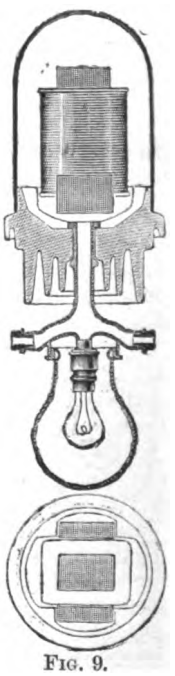

FIG. 9.

of 6in. diameter and 14in. stroke, made by the Maschinenfabrik Augsburg. On the shaft of this is the

Digitized by Google

armature of a constant-current dynamo. The magnetic field has four poles.

As regards the switching arrangements, these are different from those carried out by the company at Cologne, Amsterdam, and the projected Dresden station. The apparatus, Fig. 4, are operated by a strong lever, and the switches are all of the double-pole quick-break type. There is a triple insulation—once of porcelain and twice of vulcanised rubber. The whole of the apparatus has been tested to 10,000 volts. When synchronising resistances of asbestos cord covered with nickel wire are employed, which are switched on and off by means of plugs, the difference of phase is shown, not only by two lamps which are fed from a transformer, the double high-pressure current winding of which is fed from both machines, but also by means of a phase indicator.

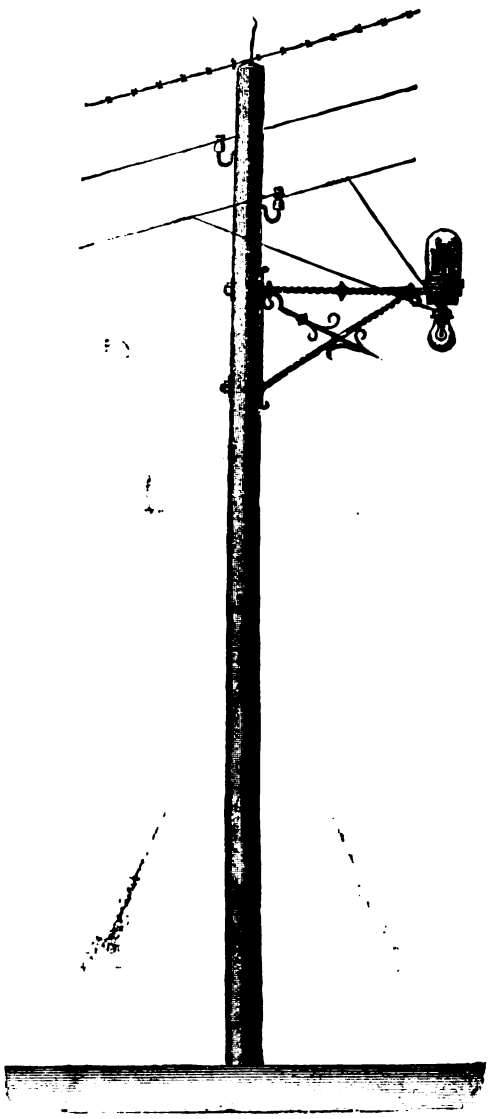

FIG. 8.

This consists of a movable disc in front of two magnet poles energised by both machines. If the phases are synchronous the disc is stationary, but if not, the disc travels in the direction of the machine having higher frequency.

For lighting the boiler and machinery houses, the walls of the lock and the harbour lights, the high-pressure current of 2,000 volts is stepped down to the desired pressure by means of Helios transformers, one of which is shown in Fig. 5. A considerable number of arc and incandescent lamps is used for the purposes above mentioned both at Holtenau and Brunsbüttel. The standards at the locks carry each four 25-c.p. lamps. The conductors are almost all underground, and consist of concentric armoured cables.

At both ends of the canal electric lighthouses have been erected. In Fig. 6 is seen the southern harbour light at Holtenau, while Fig. 7 represents the harbour lights at Brunsbüttel. For lighting the canal, which is 98 kilometres, or, say, 60 miles in length, there are four divisions, one for half the length on either side. Each division has 250 incandescent lamps of 25 c.p., so that the distance between each lamp averages between 600ft. and 700ft. There are lakes, however, on the course of the canal, and these being lighted by gas buoys, and not electrically, the electric lamps are really closer than shown by the average calculation, the distance between them varying from 260ft. to 800ft. Overhead copper conductors (·160in.) are used for the lighting of the canal. At those points where there is a lamp the leads are not cut, but the wire is wound several times round an iron core, so that a quite unbroken metallic circuit is obtained. The incandescent lamp is fed from the ends of the coil so wound.

The iron core and incandescent lamp are so made that only 9 per cent. of the power which is used at the lighting point is lost on the iron core and its windings. Should the incandescent lamp become defective, the whole of the current goes through the windings round the iron core, so that the current is uninterrupted. One-third of the 250 incandescent lamps in each section can be disturbed and out of working order without any regulation of the whole system at the central station being required. The working pressure of each lamp is 25 volts, but on account of the great resistance to be overcome when they are all in series, a pressure of about 7,500 volts has to be maintained at the terminals of the central station. This is obtained by stepping up the 2,000-volt current given by the dynamos. Fig. 8 shows the mast with lamp, which is mounted on a wrought-iron bracket, with the iron core and its windings. In Fig. 9 are represented sections of the lamp. The masts and conductors are protected against lightning by means of barbed wire.

When the installation was started, it was found that the conditions laid down for the same had been satisfactorily fulfilled. The installation works safely, is self-regulating, economical, and each lamp is independent. This satisfactory solution of a difficult problem is of much significance to the electrical industry.

For lighting the rooms at Holtenau used for the festivities at yesterday's inaugural ceremony, current was to be furnished, in addition to that required for lighting the canal and locks, for 165 arc lamps and over 500 incandescent lamps.

In fitting up the electric lighting of the canal, a 12-h.p. electric launch was employed. Its rate of speed is nine miles an hour.

THE ABSOLUTE MEASUREMENT OF ELECTRICAL RESISTANCE.*

BY PROF. J. V. JONES, M.A., B.SC., F.R.S.

(Concluded from page 691.)

We may do much better with such a tuning-fork as described. I place its slits in front of this electric lantern, in which there is a continuous arc; the light falling on the disc has passed through the slits of the vibrating fork, and by varying the rate of revolution we obtain perfectly distinct stationary teeth. Let us suppose that the fork permits the light to pass through it 128 times per second, and that the disc (the teeth on which look stationary) has 14 teeth on it, then one tooth takes the place of the next in 1-128 second, but this corresponds to 1-14th of a revolution, so that one revolution is performed in 14-128 second, and then umber of turns per second is $\frac{128}{14}=9\frac{1}{7}$.

And generally

$$n=\frac{2P}{Q},$$

where P = the pitch of the fork;
n = the number of turns of the disc per second;
Q = the number of teeth in the stationary row.

We may then make the stationariness of a tooth as seen by an observer through the slits a test of the uniformity of the rate of rotation. If a tooth begins to move past a fixed reference wire placed immediately in front of the rotating disc or drum, the observer can at once bring it back by altering the current

* Friday evening discourse delivered at the Royal Institution, May 24, 1895.

Digitized by Google

in the motor. So far as I know, this method of measuring a rate of rotation was first used by Lord Rayleigh. The method used by Macleod and Clarke for measuring the pitch of a tuning-fork bears much likeness to it.

If the tuning-fork were itself a reliable time indicator to the degree of accuracy required, we might calculate from its pitch the speed corresponding to stationariness of a given row of teeth. But my experience is that the vibration period of a fork maintained in vibration electrically is not sufficiently constant. If stopped and set going again, it may start with a period different from that of its last performance by several parts in 10,000; no previous determination of the pitch of the fork can therefore be relied on to give us the rate of rotation to that degree of accuracy, though, once started, the fork goes sufficiently uniformly to give us the means of control. The period of a bowed fork does not vary in this fashion, but it is more troublesome to use for the purpose. The constant bowing required takes too much of the attention of the observer. Accordingly, it is necessary to measure the rate of rotation during each run while the galvanometer observations are being made. This may be done telegraphically with great accuracy. The rotating disc is, by means of an eccentric attached to its axle, caused at each revolution to make and break an electric circuit passing through a Bain's electro-chemical telegraph instrument. The standard clock telegraphs seconds to the same instrument. The two records lie side by side on the same tape, and simple counting with careful fractional estimate gives with great precision the mean rate of rotation during the few minutes occupied in taking a set of galvanometer readings.

With this means of measuring the rate of rotation we may, establishing synchronism with a fork in the way I have indicated, find the pitch of the fork.

The following is a set of measurements of the pitch of a bowed fork. I bring it before you as indicating the accuracy both of the synchronising and the time measurement.

TABLE I.

Date. 1892.	Duration of observation, minutes.	Temperature Centigrade, degrees.	Pitch of fork (corrected to 15°·5 C.)
July 16	2	19 67	65·1823
July 17 (i.)	4	19 17	65·1823
July 17 (ii.)	4	19 65	65·1827
July 17 (iii.)	5	20 05	65·1814
July 18 (i.)	4	19 56	65 1809
July 18 (ii.)	4	19 92	65·1823
July 21	4	18·18	65·1812
July 22	4	17 96	65·1831
		Mean	65·1820

Extreme variation from mean is about 1 in 65,000.

§ 11. When I first began working at this method I found it extremely difficult when the disc was in rotation to obtain a steady reading at the galvanometer. My galvanometer is a very sensitive Thomson reflecting galvanometer of about one ohm resistance, made by Elliott Bros., and fitted by my assistant, Mr. Harrison, with a long suspension for the support of the needle by a quartz fibre. When the disc was in uniform rotation, the spot of light roamed continually over 50 or 100 divisions of the scale, and frequently there were sudden jerks of a most embarrassing kind. Readings with a galvanometer so sensitive were, in fact, impossible. (The scale divisions are 40 to the inch, and the scale is about 40in. from the galvanometer).

Now, the E.M.F. in the circuit of the galvanometer when there is no current through the standard coil is due to three causes:

(i.) The cutting of the earth's flux of induction by the radius of the rotating disc. The E.M.F. due to this cause is small in my apparatus owing to the fact that the plane of my disc nearly coincides with the magnetic meridian. For a uniform rate of rotation it is constant.

(ii.) The thermo-electric forces due to the general distribution of temperature in the galvanometer circuit. Changes in this distribution would be gradual, and would not account for the sudden irregular movements of the galvanometer needle.

(iii.) The thermo-electric force at the contact of the external brush with the circumference of the disc. The sudden movements of the needle were obviously due to variations in the thermo-electric force.

I made many experiments with a view of diminishing these changes. I first tried an ordinary phosphor-bronze brush made of a number of layers of thin sheet, and controlled by a spring, brush and disc circumference being well amalgamated. This was not at all successful. Trials were then made with amalgamated copper and amalgamated lead, and with the substitution of a dead-weight pressure for a spring. But no satisfactory result could be obtained. It was noticed, however, that after amalgamation the readings were fairly steady for a short interval, and it seemed likely that if mercury could be continuously supplied to the surface of contact between the brush and disc, the E.M.F. at their contact would be rendered much more constant. This led on to the idea of a brush consisting of a single wire, perforated by a channel through which a constant flow of mercury might be maintained from a cistern of adjustable height, and a brush of this description was made (Fig. 5). Trial showed that our difficulty was at an end. The variations almost disappeared, the sudden jumps quite ceased to trouble us, and the motion of the needle did not extend over more than one or two divisions of the scale for many minutes. A multiplication of such brushes round the circumference would make still further improvement.

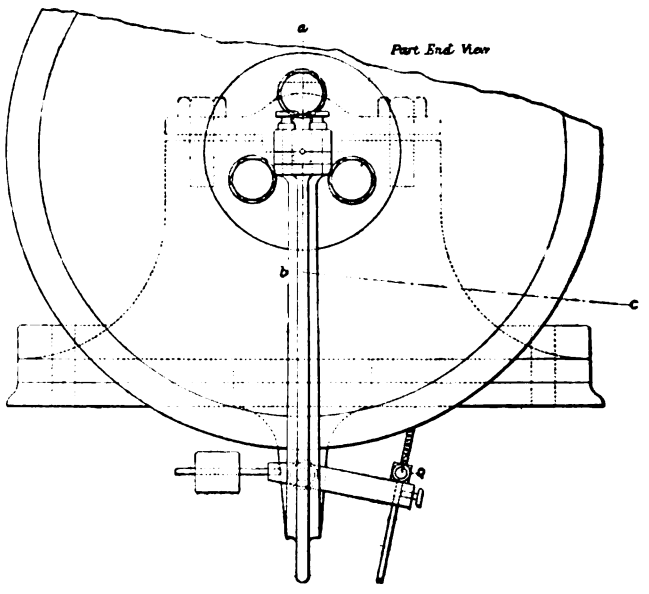

FIG. 5.

§ 12. In measuring a resistance, we have to determine what I have called the equilibrium rate of rotation corresponding to that resistance—*i.e.*, the rate of rotation—such that, on reversing the direction of the current through coil and resistance by the commutator, the reading of the galvanometer is unchanged. Now, it is not very easy to hit this exactly without making a great many trials, and fortunately it is not necessary for us to do so. The current produced in the galvanometer circuit by the difference of the E.M.F.'s at the disc and at the resistance is proportional to that difference; and if the current is small, it is proportional to the scale deflection on reversal. We shall commit no appreciable error therefore, if we are near the equilibrium rate, in assuming that the difference between the equilibrium rate and the actual rate is proportional to the scale deflection on reversal; or, what comes to the same thing, that the difference, $R - Mn$, is proportional to the scale deflection on reversal. If we take four or five rates of rotation near the equilibrium rate, and determine the deflections on reversal corresponding to each, we can by interpolation determine the rate of rotation that would correspond to no deflection—*i.e.*, the equilibrium rate. If, say, we take five such rates, some on one side and some on the other of the equilibrium rate, we get five equations as follows:

$$R - M n_1 = C l_1$$
$$R - M n_2 = C l_2$$
$$R - M n_3 = C l_3$$
$$R - M n_4 = C l_4$$
$$R - M n_5 = C l_5$$

where l_1, l_2, l_3, l_4, l_5 are the deflections corresponding to rates of rotation, n_1, n_2, n_3, n_4, n_5, and C is a constant.

Combining these by the method of least squares, we may readily obtain the most probable values of R and C. If the greatest accuracy is not required, we may content ourselves with two observations—one on one side of the equilibrium rate, and the other on the other side.

The elementary observation in the determination of a resistance with any given apparatus is, then, the determination of scale deflection on current reversal corresponding to a rate of rotation simultaneously measured. To obtain this scale deflection accurately, we must obtain it as a mean of the values given for it by a number of successive reversals succeeding one another as quickly as possible in order to eliminate slight variations in the position of the galvanometer needle due to the slight remaining variations in the thermo-electric force at the external brush contact, and the slight variations of speed that the observer at the tuning-fork has to correct. It is, therefore, best not to wait for the needle to come even approximately to rest after the disturbance due to the induction current on reversal, but to take the readings for the extreme positions in an oscillation, and having previously found the

Digitized by Google

coefficient of damping, to calculate the position of rest from these two readings.

Here is a table of an average set of such observations taken during a three minutes' run. The readings with the commutator in one division are denoted by E, and those with the commutator in the other division are denoted by W. The deflections on reversal are given in the column marked W – E.

Summing up, then, we have during an observation one observer controlling the speed by the tuning-fork method I have described ; another at the galvanometer continually reversing the commutator and calling out the galvanometer readings : at the same time the rate of rotation is being recorded on the tape of the Bain's telegraph instrument under the watchful care of a third ; and a fourth person is required to write down the readings called out from the galvanometer. The run usually lasts one, two, or three minutes according to the degree of accuracy required. The concordance of the results obtained from successive runs in measuring the same resistance is the best test of the success of the combination.

The following is a set of observations of a resistance of about 1-2,000 ohm made in July and August, 1893.

TABLE III.

These results show that no single observation differs from the mean of a number by more than 1 part in 10,000.

§ 13. We have now to consider the other factor in the resistance—the coefficient of mutual induction of the coil and disc. This depends merely on the dimensions of the coil and disc if they are accurately centred ; and as the adjustment for centre was made in between the successive sets given in the last table, we may take for granted that it can be made with the requisite accuracy. The circumference of the disc is a sufficiently true circle, the disc having been ground true in place. Disc and axle were then removed, and transferred to my Whitworth measuring machine. The measurement of its diameter presented no difficulty. It was easily determined to the 10,000th of an inch.

The mean radius of my coil cannot be determined with the same accuracy, but I believe it is known to the 1,000th of an inch. The coil consists of a single layer of silk-covered wire, wound in a screw thread cut in a brass frame. The silk covering of the wire introduces some uncertainty. It was measured bolted to its stand as in use. Measurements were taken along 18 diameters in the Whitworth machine, with the following results :

Diameter.	Measurement.	Diameter.	Measurement.
0°-180°	21·0898	90°-270°	21·1038
10-190	21·0929	100-280	21·1056

t=17° C.

These measures clearly show that the coil is elliptical in

Digitized by Google

section, the difference between the major and minor axes being about ·008in., or about 1 part in 1,300. The way in which this fact emerges from the measurements is, however, some indication of the accuracy with which the individual measurements in the machine can be made even in the case of a coil of insulated wire.

My coil, then, is faulty, on account of this ellipticity. I have not yet calculated the possible error due to this cause. It cannot be very great; how much it is only calculation can settle, and the calculation is not without difficulty. But this, after all, is only a question of my apparatus, and does not affect the general question of the possible accuracy of the method. A more solid metal frame might, no doubt, be turned true to the accuracy required, and if so turned might then be measured with the requisite accuracy in the Whitworth machine. A still further improvement may be made by making the coil frame of insulating material, say, paraffined marble, and winding on it naked wire instead of silk-covered wire. The radius might then be measured with certainty to something much better than 1 part in 10,000.

The use of a coil with a single layer of wire, instead of many layers, is a great improvement for the purposes of determining the mean radius. It, of course, necessitated the finding of a new formula for the coefficient of mutual induction. This I obtained by direct integration of the general integral for the case in point—viz., a circle and coaxial helix. The coefficient of mutual induction is given us as a sufficiently converging series involving elliptical or quasi-elliptical integrals.

We may, then, in the result conclude that though I cannot guarantee my own coefficient of mutual induction as correct to 1 part in 10,000 till I have calculated the effect of the coil ellipticity, it lies well within the resources of our mechanical engineers to make a coil and disc free from uncertainty to this degree of accuracy, and if this be so, I am warranted in stating that a resistance can be measured in absolute units to 1 part in 10,000.

Now, in the Order in Council from which I quoted in the early part of my discourse, it is stated that in the use of the ohm standard the limit of accuracy attainable is one-hundredth part of 1 per cent.—*i.e.*, 1 part in 10,000. Hence the Government gains nothing in precision to compensate for the risk it has taken in adopting as unit the resistance of a standard coil which may vary from time to time in consequence of changes in the physical condition of the coil. There is no valid ground left for adopting as ultimate unit any other unit than the absolute unit itself. We have not in our electrical standard legislation given full credit to the mechanical engineer for what he can do for us. He can make a machine that will measure resistance in absolute units with a precision as great as, I might say greater than, that with which the Government is prepared to guarantee its comparisons. Such a machine ought to be at work in the Board of Trade Laboratory in order that there may be opportunity from time to time at regular intervals to measure the Government coil or coils in absolute units. It is necessary that this should be done if we are to be guarded against the perpetual inconvenience of unknown possible changes in the coil the resistance of which is now the legal unit.

§ 14. Such a step would have collateral advantages. It would enable the Board of Trade to certify standards of low electrical resistance. With such a machine, standards of from 1-1,000 to 1-500,000 of an ohm may be measured to nearly the same percentage accuracy. All we have to do in dealing with the very low resistances is to pass a sufficiently large current through them, and shunt the standard coil of the machine. But to enter into details on this point would lead us too far. I must content myself with saying that I believe such a machine is much the best instrument for standardising low electrical resistances, and that accurate standards of low resistance would be of great service both in the laboratory and the workshop.

I have, in conclusion, only to express my obligation to my assistant, Mr. Samuel Harrison, for the great and constant help he has given me in the course of my investigations on this subject.

ELECTRICITY SUPPLY FROM TOWN GAS.*

BY F. H. MEDHURST.

It is with great diffidence that I venture to submit for the consideration of this influential institute a few important questions in connection with the supply of electricity from central generating stations for public and private purposes. It will probably be freely admitted by every member of this society that the electric light has come to stay; and that in every town of even average importance there are a fair and increasing number of persons desirous of having their business or private premises electrically illuminated—even though the cost, in the great majority of cases, be greater, light for light and time for time, of the electric than the gas light.

* Paper read at the annual meeting of the Incorporated Gas Institute at Edinburgh, June 14.

It is no longer necessary to urge, in a paper like the present, the numerous and unique advantages of electric light, because they are now almost as freely recognised by gas engineers as by electricians. But if the proposition that electricity supply from central stations has been established on a thoroughly sound financial basis be not accepted without doubt or question, then I think that the fact that local authorities are everywhere establishing electricity supply works, and that in 1894 these works were in the proportion of 10 to 1 as compared with those started in the same year by companies, must carry conviction to the minds of the most sceptical; for we do not find local authorities in Great Britain recklessly investing public funds in undertakings that have not given unquestionable proof of their lucrative character.

Nevertheless there can be little or no doubt that the number of electricity supply works in existence, and in immediate contemplation, would be greater than is actually the case but for the strenuous opposition which the electric lighting industry has from the commencement sustained from almost all those interested in the maintenance and development of the gas industry. From time to time it has been attempted to pacify this opposition by reminding shareholders in gas companies, and gas engineers and managers, that actual experience has hitherto demonstrated that in towns where central electric lighting stations have been erected, the consumption of gas has actually increased instead of decreased. It has been plausibly, and not altogether unreasonably, asserted that the advent of a public and private supply of electric light has improved the general standard of lighting; and that those who have preferred to retain gas have been forced by sheer competition to add considerably to the number of jets in their shop windows and shops, in order not to be outdone by those in the same line of business who have adopted the new illuminant.

Then, again, I think it must be admitted that heating and cooking by gas have received a great impetus since the advent of the electric light, and, generally speaking, the fact that the managers, directors, and engineers of gas undertakings have been "put on their mettle" owing to competition with what was formerly almost a monopoly, must in some measure account for the apparent paradox that in districts possessing a public and private supply of electricity the consumption of gas has continued to increase.

But to infer from this undoubted fact that the last word has been said with respect to the competition between gas and electricity would, I think, be highly injudicious. My own opinion is most emphatically that the effects heretofore observed, and that I have tried to explain, are merely transient in their nature; and I think that a very little calm consideration must show that to maintain that because hitherto the consumption of gas has not been seriously affected by the use of electricity therefore it never will be prejudicially affected, is to display ignorance or disingenuousness. With respect to my contention that, in the long run, an increased demand for electricity in a particular district must decrease the demand for gas in the same district, I will say at once that if electricity could only be used for lighting I should be of a contrary opinion, because so long as the demand for the electric current be satisfied by a use of the generating plant in the 24 hours equivalent to only an output of the plant for from three to five hours at full load—so long, I say, as electricity supply works continue to suffer from very small load-factors and from very imperfect means of storing electrical energy will it be impossible to sell electricity for less than from 6d. to 8d. per Board of Trade unit; and I do not think that gas companies have much to fear whilst these rates are a necessity. On the other hand, I believe that there are abundant indications tending to show that these prices need not long remain necessary. Cooking by electricity has produced excellent results. At least one London theatre has been heated throughout by electricity; and electric motors are probably the cheapest, most efficient, and most convenient motors for small powers. In a word, I do not think it too much to say that electricity from town mains is capable of accomplishing everything that may be done by town gas, with the almost single exception that electricity will not contaminate the atmosphere we breathe.

Electrical engineers recognise that the cheapening of the electric current produced at central stations depends in a very great measure on the extent to which electricity comes to be used during the day time, and, generally, during the time when the generating plant is not required for lighting purposes. I have purposely gone rather fully into the question of the by-uses of electricity, because it is by their development that electricity will, I believe, before this institute has held many more meetings, be sold for all purposes for from 2d. to 3d. per unit. I admit that I am only prophesying; and it is for you to examine the premises which have led to my conclusions. At all events, it is certain that if the plant at our generating stations could be worked at full load, and without the intervention of electric accumulators, for 20 hours out of the 24, then the electricity produced could be very profitably sold for considerably less than 3d. per unit.

Digitized by Google

But if this thing comes to pass—as, rightly or wrongly, I am convinced it will—what will be the effect on the gas undertakings? If the electricity be produced—as is now usually the case—through the intervention of steam-boilers and steam-engines, then I make bold to say the result will be to very seriously cripple at least a great number of the gas undertakings in this country. It is, I fear, too late in the day for gas companies in important towns to apply for electric lighting provisional orders, because in most cases they would be met by a counter-application from the local authority; and the latter would certainly succeed. But in Great Britain, especially in Scotland and the North of England, many of the gas undertakings are in the hands of the local authorities themselves. In some of these towns electricity supply works have been erected by the local authorities; but in every case, with the single exception of Belfast, the dynamos have been driven by steam-engines, though in one or two instances coke breeze—which has formerly been worth little or nothing—has been used for raising steam in the boilers. In these cases forced draught has, of course, been a necessity. No doubt this plan is economical for the present; but what of the future? What of the time when electricity comes to actually, and most seriously, decrease the demand for gas? Then the demand for electricity will be greater than that for gas; and as the demand for gas decreases less breeze will be made, and there will be necessarily less of it to burn in the boilers, so that steam coal will have to be at least partially resorted to.

Hitherto, then, with the single exception of the Corporation of Belfast, no local authority appears to have recognised that there is no great advantage to be derived from founding one kind of lucrative business if that business is to proportionately reduce the profits of an existing and a paying undertaking already in the possession of the ratepayers. In my opinion, there is one way, and one way only, whereby electricity supply works can be so carried on as to permanently benefit, from a commercial standpoint, the gas undertaking. Obviously this is a consummation devoutly to be desired—at least, in those cases where the gas and electricity supply businesses are in the possession of the local authority, or where (if there be such an example) both belong to the same company. In my opinion, the problem is only to be solved on a permanent and sound financial basis by the employment of gas-engines, actuated by town gas, to drive the dynamos. It may, of course, be said that if this plan be adopted we shall be forced to employ secondary batteries and low-tension direct-current distribution, because it is frequently urged that the speed of gas-engines fluctuates too much to render direct driving advisable. Personally, I must dissent from this view, because I have had opportunities of testing the gas-engines of some of the leading makers, with the result that I am convinced of the possibility of manufacturing gas-engines whose momentary variations of speed under sudden differences of load and cyclical variations are no greater than those of a well-governed steam-engine. I admit that, in the case of the gas-engine, an even turning moment with rapidly fluctuating loads is obtained solely by storing up, as it were, a relatively great number of revolutions in the flywheel—*i.e.*, by employing a very heavy flywheel, rendering advisable a substantial outer bearing. The result is, of course, to increase the consumption of gas at all loads, though the increase is especially felt at light loads. Nevertheless, there is a greater margin for improvement in the gas-engine than in the steam-engine; and I trust that before long we shall have gas-engines running, not with fewer explosions at light than at heavy loads, but with weaker explosions, as it will then almost certainly be possible to reduce the heavy gas-engine flywheels, which have attained almost alarming dimensions.

But taking the gas-engine as it is, I propose to try and demonstrate the effect that would be produced in the event of a local authority, owning the gas undertaking, deciding to employ these engines for its electricity supply works. I assume that the electrical system adopted be the alternating high-tension system, with transforming sub-stations. Whether steam-engines and boilers, or gas-engines and no boilers, be employed, the capital outlay on mains and transformers would be the same. In the case of a plant of 180 units, split up into three sets of 60 units (one spare) each, I find that the cost, using Lancashire or water-tube boilers, steam alternators (alternators coupled direct to high-speed steam-engines of the single or double acting type), a feed-water heater, and economiser, is about £600 more than a plant for the same output employing three gas-engines of 110 b.h.p. each, to drive the three alternators with direct-coupled exciters, by means of ropes or belts. In the former instance, I have assumed that the exciter engines are to be coupled direct to their dynamos, but that the exciters are not coupled direct to the alternators. I believe that no adequate advantage would be gained by employing separate gas-engines to drive the exciting dynamos, because I am of opinion that, for various reasons which need not here be discussed, parallel running would not in the case of a gas plant be practicable. But that parallel running of alternators is by no means essential to commercial success, is sufficiently proved by the fact that the Newcastle and District Electric Lighting Company—one of the most successful electricity supply companies in England—has never attempted it.

I do think it unreasonable to count on a saving of about £400 in the buildings and foundations necessary to accommodate the gas plant above mentioned, as compared with the outlay that would be requisite for corresponding steam plant. In the former case neither chimney-shaft nor boiler-house are necessary; whilst in the latter the engine and dynamo room must be rather larger and its foundations more substantial than that for the steam plant. If, then, the total capital saving due to the employment of gas plant be £1,000, and if the local authority borrow at 3 per cent. and set aside 2½ per cent. for redemption of the loan, we have a saving of £55 per annum due to the employment of gas plant. Assume that there be no public electric lighting, but that the equivalent of 6,000 lamps of 8 c.p. and 30 watts be connected to the mains, it is fair to reckon on a yearly consumption of 18 units per lamp. The output would therefore be 108,000 units per annum.

The following table, compiled from the Board of Trade returns, shows the cost of production and distribution per unit delivered to consumers from central stations whose outputs in 1894 varied between 60,000 and 200,000 units. A Board of Trade unit of electricity will maintain an 8-c.p. (30-watt) lamp for 33 hours.

Name of town.	Number of units delivered to consumers.	Costs of production and distribution.				
		Coal.	Oil, waste, water, etc.	Salaries and wages.	Repairs and maintenance.	Total.
	d.	d.	d.	d.	d.	d.
Aberdeen	65,012	0·65	0·21	0·85	0·07	1·78

Taunton	100,495	1·95	0·48	0·79	0·32	3·54
Northampton.	59,474	1·51	0·20	1·55	0·31	3·57
Scarborough..	86,594	1·87	0·13	1·57	0·70	4·27
Oxford	157,257	0·65	0·05	0·92	0·58	2·20
Sheffield	192.220	1·00	0·14	1·20	0·42	2·76
Average ...	110,386	1·13	0·18	1·09	0·36	2·76

As the average output of the stations named is 110,386 units, I think we may take the average costs of production as representing what might reasonably be expected to follow the completion of such an installation as I have imagined, using steam plant, and designed so as to economically meet the requirements of the case.

Now we have to consider what are the costs of production under the four separate heads mentioned in the table, and what the total cost of production would be if the steam plant were replaced by gas plant. It is well known that gas-engines of 100 b.h.p. and upwards are now made to consume not more than 20 cubic feet of town gas per horse-power per hour at full load. But, unfortunately, the conditions of electricity supply are such that the engines would, for the most part, be working much under full load; and I should not anticipate an average consumption of gas of less than 80 cubic feet per unit sold to consumers, taking into account the trying conditions under which the engines would be working. Now, I am informed, on excellent authority, that 1s. 2d. is a fair price to allow as the cost of producing 1,000 cubic feet of gas, including interest on capital expended on the works (but not on mains), and also cost of labour and material. I am assuming that the town has a population of about 50,000; that the electricity supply works are erected at the gasworks; and that the latter are well designed and efficiently managed. The cost of production must vary between fairly wide limits; but it is necessary to assume a definite figure for the purposes of this paper, and those engineers who know that their costs are lower or higher can make the necessary deductions for themselves. But, allowing the above assumptions, the cost of gas per unit sold to consumers works out at 1·12d. per unit. In the case of the steam plant, the average cost of coal was 1·13d., and the highest 1·95d. Oil, waste, water, and engine-room stores would probably be about equal in both cases. I should expect salaries and wages to be rather less in the case of gas than of steam plant, because in the former the wages of stokers will be saved, and the gas engineer and manager may, with a little technical assistance, manage the electricity supply works as well. Repairs and maintenance will, most likely, cost somewhat more for a gas than a steam plant, though the difference must be small. The saving in salaries and wages would probably rather more than cover the extra cost of repairs and maintenance. The net result, then, would be that the costs of production would most likely be almost identical in both cases; whereas the advantages, in point of view of decreased capital expenditure, and hence of interest and sinking fund, appear to me to be decidedly in favour of the gas plant.

Vol. XIV. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers or binding can be obtained, price 2s.

THE LAMP INDUSTRY.

The inspection of a new, or comparatively new lamp factory, naturally leads to a consideration of the present position of the incandescent lamp industry. History tells us that the incandescent lamp manufacture was for some years a monopoly, and justly so, in the hands of the patentees, or in those of a company formed under their auspices. We have never been amongst those who begrudge a patentee a full and ample remuneration for the outcome of his experimental researches. The man who makes a utilitarian discovery is a benefactor to his kind; he often, as in this particular case, is the means of starting and developing quite a new industry, and when thousands, if not millions, benefit by his labours he should not lack appreciation and due reward. According to the law of the land, the monopoly of the patentee ceases after a certain number of years, and he is supposed, as the Americans would say, to make his pile during that period. It is certain, however, that as soon as a patent of this kind runs out competition will begin, and this has been the ordinary course with the incandescent lamp. Towards the close of the period during which the patent lasted promises of cheaper lamps were made on every hand, and as soon as the patent lapsed, such lamps were put upon the market. One question may now be asked, for sufficient time has elapsed to provide an answer. It is this: Are the cheap lamps really cheap and satisfactory? We are inclined to answer this question in the negative. Many of the cheap lamps have been found to be failures, and purchasers have found in the end that a dearer lamp would really have been more economical. One reason for this is not far to seek, and we may be pardoned for calling attention to it. In any manufacturing process of a delicate nature, it is impossible to so organise the manufacture that each several product is perfect; hence the production of what may be termed wasters. A well-conducted factory—one whose owners seek constant business, repeat orders, and a good reputation—condemns these wasters, not one of which ever wilfully leaves the factory. The destruction of these wasters increases the prime cost of the perfect product. Take this case of incandescent lamps, and suppose that 50 per cent. of the lamps upon completion and testing are found imperfect, then for every hundred lamps made only fifty ought to be sold—the remainder should be destroyed. Of course, this percentage of wasters is probably too high; but if we were to indicate that one-third of the lamps made were imperfect, we should not be far from the mark. Now, if a factory, instead of carefully testing and destroying wasters, is careless and allows them to mix with perfect lamps, the result is a lesser prime cost on the books, and this permits selling at a lower price. It may be argued that, so far as the user is concerned, it does not really matter if he pays, say, a shilling per lamp and loses one in three, or if he pays one shilling and sixpence per lamp and loses none. From a theoretic monetary point of view, perhaps, there is no difference, but from a business

Digitized by Google

point of view there is a great difference. The purchaser or the purchaser's clients are disgusted at finding so many bad specimens; and as a matter of practice, in contradistinction to theory, a number of bad lamps upon a circuit do lead to greater cost, and may lead to the destruction of good lamps. The tests of lamps for economy are exceedingly interesting, but this is not the moral we have to inculcate here. We have rather to insist upon purchasers being cautious in buying so-called cheap lamps. The Edison-Swan Company before the expiration of the monopoly had reached a certain excellence of manufacture, and their productions might be taken as a standard. They naturally lowered their prices, while retaining this excellence; hence buyers had some clue as to what might be considered good and what might be looked upon as inferior. If other makers put into the market lamps not inferior to those of this standard at a lower price, that is a legitimate method of competition against which we have no word to say; but if prices are lowered because an inferior article is to be sold, then the purchasing public must suffer. The reputation of a firm is of the utmost importance in business matters of this kind. The trade can and ought to speak positively to its clients, and refuse its patronage to any doubtful products. They know—what the general public do not and cannot know—whether the goods offered are by a firm possessing the necessary knowledge and experience to turn out good work; and if they are satisfied in this respect, there is no objection to recommending the articles offered. Still, dealing with this special question of incandescent lamps, it is well known that the experience and knowledge necessary for the production of good specimens is spread over a limited number. The processes are not all patents—some are trade secrets, and a lack of knowledge about these secrets leads to the production of an inferior article. Here, again, the trade has a grand opportunity of exercising a precautionary discretion and hesitancy in recommending aught that fails to meet their demands in this direction. Briefly, then, we say there should be a recognised standard of excellence, the ability to produce lamps of this standard is in the hands of but few, that firms having a good reputation will not offer products below such standard, and it is wise and economical in the long run to deal with such firms rather than to purchase because of initial cheapness.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

COST OF PRIVATE LIGHTING.

SIR,—I have had my attention drawn to extracts from my report and tests of private generating plant at the Olympia which appeared in your issue of the 14th inst., also your editorial comments thereon.

In reply, permit me to thank you for your remarks as to the usefulness of such information, and at the same time state that the estimated costs which are given were not embodied in my report, but have been deduced by the contractors.

Engineering of June 29, 1894, contains a series of comparative tests and costs of private generating plants compiled by the writer, and in which the annual cost of maintenance, etc., is taken from actual working.—Yours, etc.,

THOS. HANNING.

Newcastle-on-Tyne, June 19, 1895.

"HUNNINGSCONE" MICROPHONE TRANSMITTER.
(DECKERT PATENT No. 21,565.)

SIR,—As it has come to our knowledge that certain manufacturers of microphone transmitters are adopting the name of our transmitter known as the "Hunningscone," and are advertising their own wares under this title, with the result that some of our customers have been thereby imposed upon, we beg to offer the following explanation: We are the originators of the name "Hunningscone" as a name for Hunnings transmitter, and that name was suggested by the fact that the internal construction of our transmitter necessitated the use of a number of cones or pyramids arranged in a peculiar manner, to which is due (in conjunction with other details) the excellent effects obtained. This transmitter is manufactured under the Deckert patents, and is the same as now used in large quantities by the General Post Office on their long lines, including the trunk lines recently opened between London, Glasgow, and Dublin, and is also universally adopted by the National Telephone Company. Intending purchasers therefore would do well to be quite sure that they are obtaining the genuine article, manufactured to the Deckert patent specification, otherwise they are not obtaining the original "Hunningscone," but something which must necessarily be inferior, or the manufacturers would not be pushed to such straits as to purloin a title for it. At the same time it speaks well for our transmitter that trade competitors should, as a guarantee of excellence, advertise their supplies under titles which have appeared in our catalogue for the last three years.—Yours, etc.,

THE GENERAL ELECTRIC COMPANY, LIMITED.
(Max Binswanger, Director.)

London, E.C., June 18, 1895.

DUBLIN TRAMWAYS.

SIR,—Mr. Stephen Sellon wriggles beautifully. As he is evidently a wordy letter-writer only, and produces no facts, I must now decline, until he has done so, to further discuss the matter with him.—Yours, etc.,

JAMES L. OWEN.

120, Colmore-row, Birmingham, June 15, 1895.

CITY AND GUILDS EXAMINATION.

We have duly received a number of papers in answer to our announcement of May 10. These papers have been sent to the gentleman who has undertaken their examination, and his award will be made as quickly as possible.

THE ROBERTSON INCANDESCENT LAMP.

When the electric light as produced by an arc lamp demonstrated to the public at large the practicability of its adoption as an artificial light, it was apparent to the most ignorant that its sphere of usefulness was limited. But in 1878 the irrepressible journalist who delights in impossible science, flooded the English papers with an account of an American invention whereby the electric light may be sub-divided to infinity, exactly as obtains in the case of gas installations. Upon this bare assumption a panic ensued in the gas market, and £100 shares which were worth £188 fell rapidly to £135. This *ignis fatuus* was but an experimental lamp made by Edison, in which a loop of platinum in vacua was rendered incandescent by the passage of an electric current. But Mr. Swan, an English scientist, had already for 20 years been experimenting with true carbon filaments, and in 1877, in conjunction with Mr. Stearn (a gentlemen whose original researches in the production of high vacua rendered such lamps possible), a

Digitized by Google

number of lamps were made with filaments of carbonised cardboard. As a matter of history, therefore, the incandescent electric lamp in its practical form is essentially a British invention, both as regards primary inception and evolution. Platinum, although sufficiently illustrative from an experimental point of view, is not suitable for a practical lamp. Until the publication of the Swan-Stearn patent nothing was done in America respecting the use of carbon for filaments, Mr. Edison having in the meantime devoted all his energies to the perfection of the platinum filament. But upon the publication of the British patent, platinum was cast aside, and the fauna and flora of the whole world ransacked to produce a carbon. As a matter of fact, neither Mr. Swan or Mr. Edison have any claim to the use of carbon and vacuum, singly or combined. They used a finer thread of carbon than previous experimenters, who doubtless had been limited in this matter by the extreme difficulty of procuring thin carbon rods, and, of course, a good vacuum was an essential. M. Gobard, in 1838, published a monograph on the use of thin carbon as a conductor in vacuum, and the incandescence of carbon in vacuum was patented by King in 1845. The real improvements, therefore, consist in the modes of obtaining a "carbon wire," and in the structural details of the lamp itself. It is a remarkable fact that Edison and Swan both claim a definite principle in producing the carbon filament. This procedure is, in law, fallacious. But whatever benefit attaches to priority, Swan is an Englishman, and the British nation collectively claim it as their own. The courts of law decided differently at the termination of the famous trial, and any intelligent person, upon carefully studying without prejudice, the case as presented, cannot fail to be astounded at the result. The final effect was the establishment of a monopoly, which practically checked the progress of the industry until 1893, when the expiry of the patents opened up business. By this time, however, the foreign manufacturers had the lead, and poured their goods into the English market.

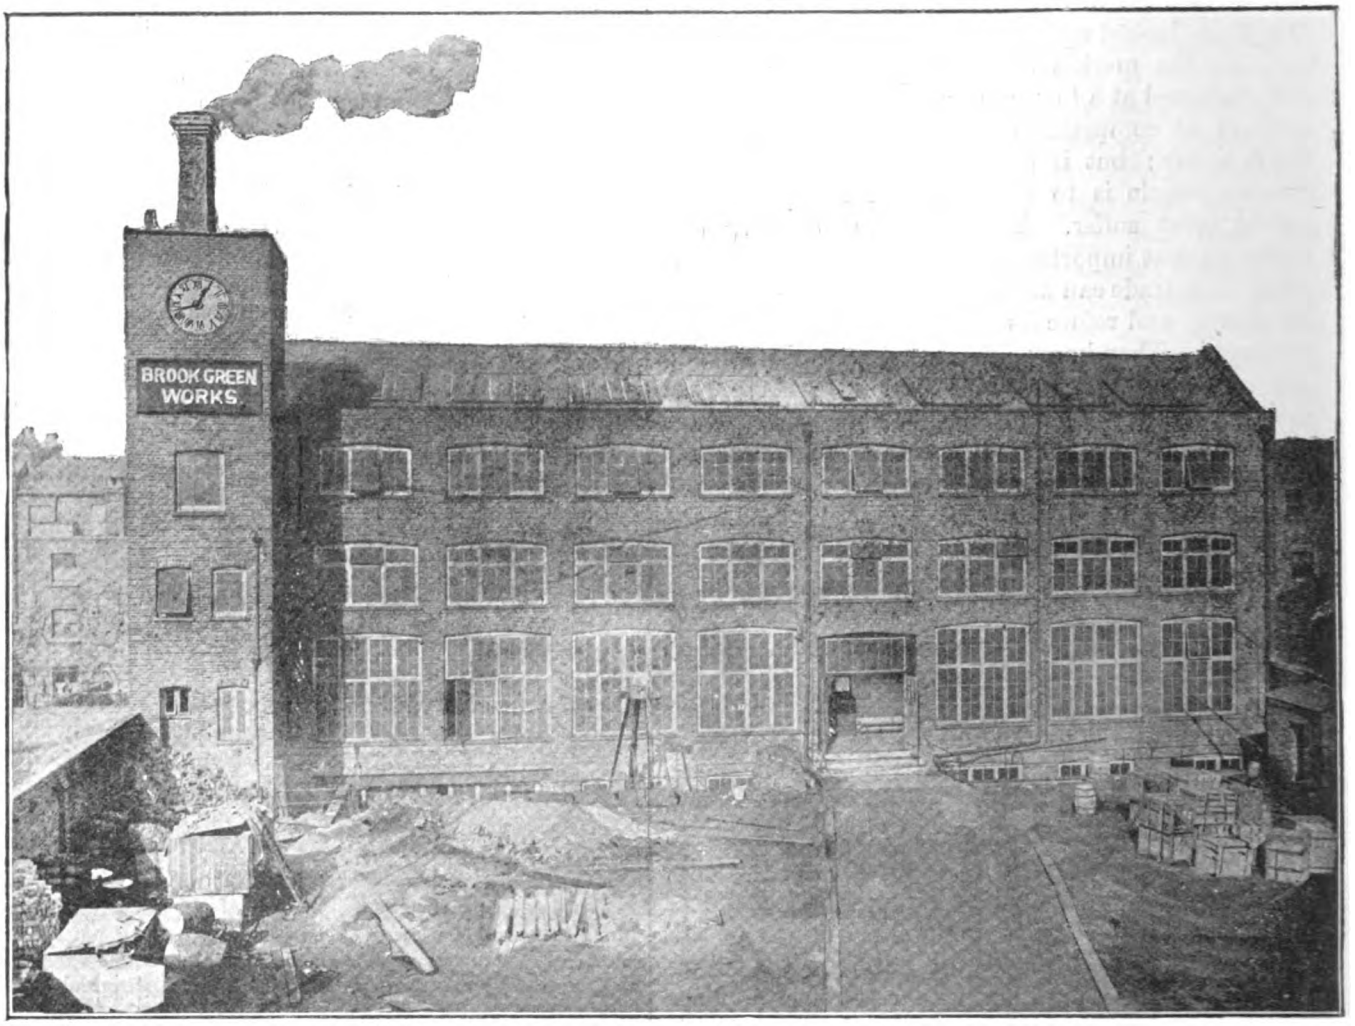

FIG. 1.—The Works of the Incandescent Electric Lamp Company at Brook-green, Hammersmith.

The English makers of incandescent lamps had in the past been crushed one by one, and the whole trained labour been gathered into the shops of the monopolising firm. It follows that individual effort had been stifled except in those gentlemen holding good positions in the one remaining lamp-making firm. So, on the expiration of the master patent in 1893, the technical knowledge in England on the subject was extremely limited. The continental makers had, on the other hand, enjoyed freedom of investigation and an extended market, so that they were ready to send lamps into our country at a very low rate.

It is needless to state that many of the lamps thus thrust on the public were, on account of their bad qualities, unworthy to receive the slightest support. After experience with the good lamps hitherto used by compulsion, the public had lost their keen powers of discrimination, and hence were and are deceived. The Incandescent Electric Lamp Company, Limited, was then started, and set about to remedy the evil, and to endeavour to resuscitate an English industry hitherto repressed. The first thing to be considered was to produce a lamp which, while being in points of efficiency and reliability the best on the market, at the same time could compete in price with the imported lamps. They selected the "Robertson" lamp, the distinguishing feature of which is the constituence of the carbon conductor, which, instead of being filamentous from the first stage of its manufacture, does not become so until several processes are carried through. The carbon is precipitated from a solution, and as a semi-fluid is ejected under pressure through orifices, the sizes of which are determined by the requirements of the lamps.

The company were fortunate in securing the services of the inventor, Mr. C. J. Robertson, as general manager, a gentleman who commenced his experience of incandescent lamp manufacture by holding an important technical position in the Lane-Fox department of the Anglo-American Brush Company in 1881. Since then he has unceasingly followed up the practical manufacture of incandescent lamps

Digitized by Google

at home and abroad. Bringing such an experience, combined with a thoroughly technical and practical knowledge of his speciality in all its details, Mr. Robertson, under the auspices of the company, vindicated the home industry, and showed that we can hold our own in spite of the advantages of the foreigner in the past. The works, which our representative visited recently, are situated at Brook Green, in the West Kensington district of London. A plant capable of turning out 4,000 lamps per day is now at work, and there is ample area available to admit of this output being doubled as the demand increases.

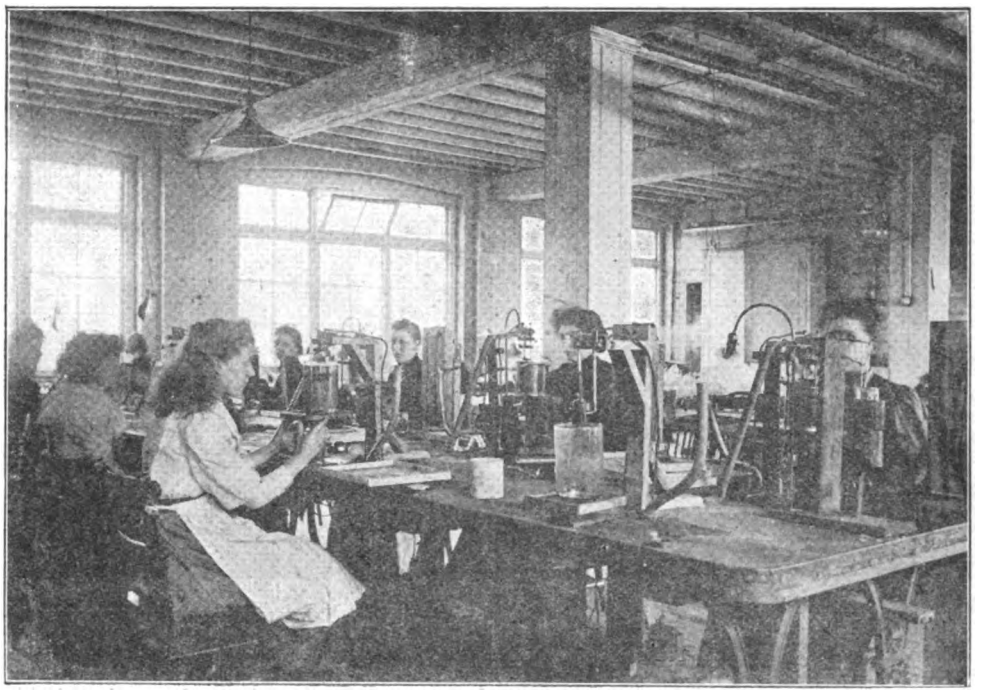

FIG. 2.—View of the Filament Mounting Room, showing Apparatus for Cementing the Junction of the Carbon Filament to the Platinu Wire.

The greatest initial difficulty to be overcome was the education of the hands, for the company determined to employ British labour, and such as had had previous experience in lamp making were used only to the obsolete systems. Therefore an expensive and tedious course of training had to be undertaken before the staff became proficient.

At present about 150 hands are regularly employed in the factory on the various operations connected with the lamp manufacture. The whole of the workrooms are airy, and in most cases they are well lighted. The exception to this last clause are the glass-blowers' rooms and the photometric rooms, where good light would naturally not be wanted. The most of the work is piecework, but the girls, who form the bulk of the staff, can and do earn salaries ranging from 12s. to 24s. per week in the ordinary departments, special hands receiving more. Our representative was struck with the interest shown by them in their work, and our illustration will give a good idea of the pleasing appearance of the staff generally. The details of the construction of the Robertson lamp are so numerous that it is impossible to do more than give a brief outline of the various operations. The raw material enters at the ground floor and gradually ascends; the finished lamps, after being packed, are let down through a tubular fire-escape into the carts standing below. We understand that on emergencies the canvas tube so used is capable of taking the members of the staff, and that all have been down it at least once.

FIG. 3.—Filament Mounting in Various Stages.

metallic lustre, so flexible and strong that it can be pulled out straight without fracture, even in its unflashed condition, as when taken out of the crucible. The material is so hard that it will scratch glass.

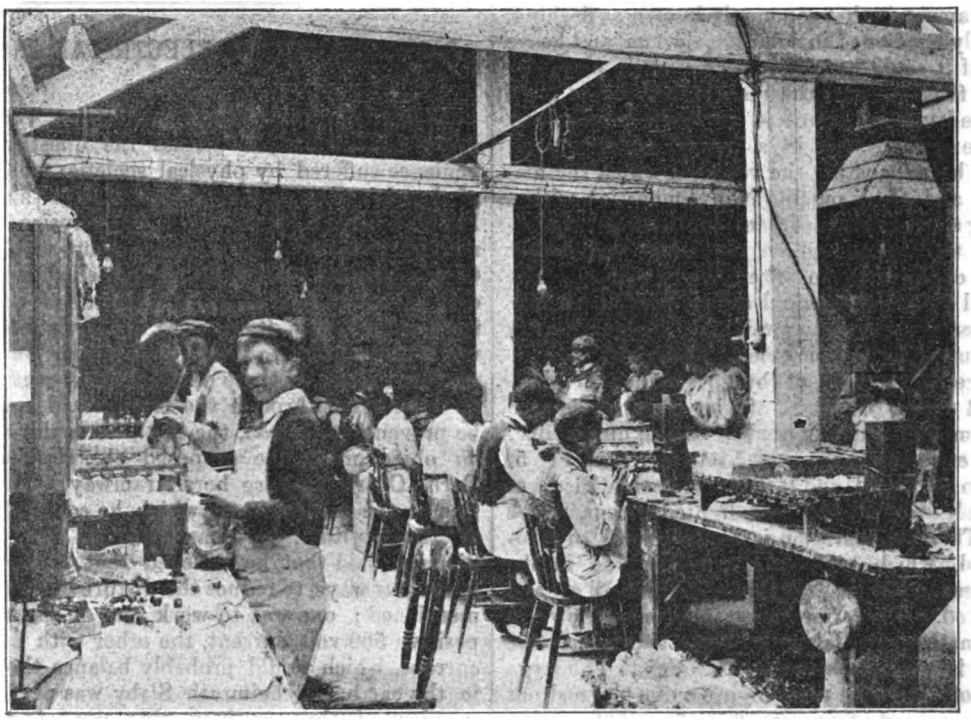

FIG. 10.—Capping Room.

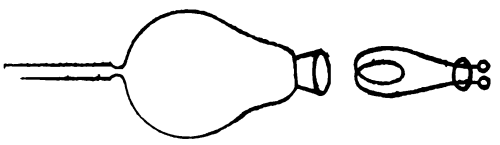

FIG. 7.—Globe Opened Out to Receive the Filament.

Moving up to the next floor, we come to the filament mounting department. A neat little machine, driven by a small motor, receives the platinum wire and cuts it up into the desired length. Two of these platinum wires are then mounted in glass at the correct distance apart. A small tube is formed at the inner end of each wire, into which the filament is slipped. A slight pressure with a pair of pliers fixes it temporarily, and the mounted filament is then taken to the table shown in Fig. 2. The

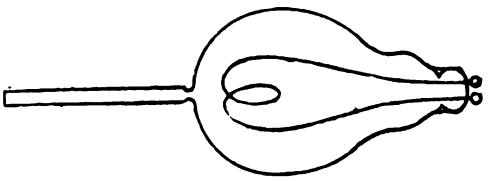

FIG. 8.—Lamp Ready to be Exhausted.

platinum loops are then connected up to a low-voltage supply, and the whole of the parts are immersed in some hydro-carbon solution. The filament is short-circuited by two clips, and the current passing them develops strong local heat at the junction of the carbon and

FIG. 11.—Cleaning and Ornamenting Room, showing Sand Blast in Further Corner.

Digitized by Google

platinum, causing a good deposit of carbon at this place. Fig. 3 shows a view taken from another part of the same room, which gives a good idea of the excellent accommodation provided for the staff. The next operation on the carbon filament is that commonly known as flashing. This is necessarily conducted in a darkened room, and hence no photograph of it could be taken. The weak places in the filament are filled up, and the resistance of those to be used in the same type of lamps is rendered uniform by incandescing the carbon wire in a hydro-carbon vapour. This is obtained by exhausting the vessel in which the filament is placed and then putting it in connection with a bottle containing some mixture of benzine with other hydro-carbon liquids, the vapour given off being sufficiently rich in carbon compounds to effect the purpose. The various taps and switches required are so interlocked that there is no danger of an explosive mixture being formed in the globe and ignited by the incandesced filament.

The next stage is carried out by girls skilled in glass-blowing. Fig. 4 shows the shape of the glass globe as it comes from the mound which is used to ensure uniformity. These globes, after cleaning, are passed into the room, Fig. 5. This room is also darkened, and it was extremely difficult to take a photograph even of the best lighted corner, which we illustrate. The first operation is to fix a small tube on to the large end, which tube is afterwards used in the exhausting process as the passage through which all air and gases are extracted. The after-appearance is as shown in Fig. 6. Then another girl takes the globe and inserts the filament. This is most interesting to watch. The large tube is drawn off, and the remaining portion opened out to admit the mounted filament, Fig. 7. This being inserted, the hot glass is pressed back and united to that round the platinum wires. When finally sealed in, two indentations are made to give a good hold in the plaster when the capping operation is effected. After this the appearance is as in Fig. 8. The lamp then, after careful examination to ensure that the sealing-in process has been effectual, is passed into the exhausting room. The bulbs are sealed on to the exhausting tube of the pumps and a vacuum produced. During the process, which is commenced by mechanical pumps and finished by mercury-pumps of the Sprengel type, heat is applied to ensure that all volatile substances are evaporated both from the filament and the globe. A current is passed through the filament during the final stages, the lamp being considerable overrun. When the gauges show that exhaustion is complete, the lamps are sealed up and removed. The mercury-pump arrangements are exceedingly well designed, to ensure automatic raising of the mercury, and it is noteworthy that in no place is the mercury free to vaporise into the air of the room. Hence the operatives are not in danger of mercury poisoning.

The lamps now undergo most critical tests in the photometric rooms, etc. This department might well be associated with a court of justice, as only some 100 out of every 150 lamps succeed in establishing their right to circulate in society. The candle-power, voltage, and watts per candle are ascertained for each lamp, and most accurate subdivisions are gone into so that the necessary E.M.F.'s shall be given, even to half a volt. Then the lamps passing this test go into the hands of the three ladies shown in Fig 9. There the lamp is subjected to various processes, such as burning in series to prove uniformity of filament, of flashing with momentary current to discover weak places in the filaments, etc. Such lamps as do pass these exhaustive trials successfully are then capped in the room shown in Fig. 10. The mountings necessary to enable the lamps to fit the various makes of holders are attached by means of plaster. After the lamp passes through the drying-room, it is again carefully tested for contact, vacuum, etc, and the neatness and exactness of the capping ascertained. The etching of the word "Robertson," together with the candle-power and voltage, is carried out, and the lamps are cleaned and ornamented, if necessary, in the packing-room, shown in Fig. 11. The frosted globes are subjected to a sand blast, which can be seen in the further corner of the room. There is again a final test of the normal E.M.F. just before the lamp is packed and despatched.

The whole of the work is under the direction and supervision of Mr. C. J. Robertson, who devotes careful personal attention to the smallest details in manufacture.

DISTURBANCE OF ELECTRICAL INSTRUMENTS.

A meeting of the Elektrotechnischer Verein was held in Berlin on June 11, to discuss the question of the inconvenience suffered by physical societies from the proximity of electric railways, and the remedy for this inconvenience. Dr. Kohlrausch, president of the Physico-Technical Imperial Institute, referred to experiments which took place at Charlottenburg on May 27, and which showed that the delicate electrical measuring instruments of that institute suffered considerable disturbance, the deviation of the galvanometer amounting to 1'·12", and totally obviating accuracy of observation. If these derangements caused by the return of the current through the earth could not, as he feared, be prevented, he said, the institute could not help raising an objection to the proposed electrical working of the Berlin-Charlottenburg horse tramway. The highest deviation of the galvanometer which he could allow, as director of the institute, he remarked, was 6". Herr Wilh. v. Siemens said that he believed that it would be possible, in various ways, to reduce the disturbances to the maximum mentioned; one was to work one of the two tracks with positive 500-volt current, the other with negative 500-volt current, which would probably balance the return current in the earth. Geheimrath Slaby was of the opinion that, in view of the ever-increasing use of electric traction, physical societies must resign themselves to the inevitable, and learn, by improving their instruments, to combat the derangements; but Dr. Dubois energetically opposed this view, because the apparatus had already reached the limits of sensitiveness. Dr. Kohlrausch then read a passage from a letter of Werner von Siemens, referring to the institute, who warned electrical engineers, in their own interest, to give due regard to the claims of science. Prof. Dorn recommended, in conclusion, as avoiding the difficulty, the adoption of the double-trolley system of electric traction.

ELECTRIC LIGHTING ORDERS.

The following special reports by the Board of Trade under Section 1 of the Electric Lighting Act, 1888, have been issued:

(1) *Strand District Electric Lighting Order*, 1895.—The Charing Cross and Strand Electricity Supply Corporation, Limited, applied for a provisional order in respect of the district of the Strand Board of Works. The Board of Works, who are the local authority under the Electric Lighting Acts, on October 10 last passed the following resolution: "Resolved, that upon the terms stated in the report" (presumably the report of a committee of the Board to whom the matter has been referred) "the consent of the Board be given to the application of the Charing Cross and Strand Electricity Supply Corporation, Limited, for a provisional order to supply with electricity all the parishes forming the Strand district, and to their application to lay mains in the parish of St. Paul for the purpose of supplying electricity in the parish of St. Martin-in-the-Fields, and that as amended the report be adopted." And on April 10 last the following further resolution: "That subject to the alterations in the model form of provisional order provided for by the agreement" (an agreement proposed to be entered into by the Strand Board and the promoters of the order), "being sanctioned by the Board of Trade, the assent of the Board be given to the application of the Charing Cross and Strand Electricity Supply Corporation, Limited, to supply electricity within the Strand district." The alterations referred to in the latter resolution were accepted by the promoters, and some of them were adopted by the Board of Trade and incorporated in the order. Others consisted of detailed provisions as to the situation, construction, and size of the works incidental to the supply of electrical energy, which were to be constructed by the undertakers in the public streets and the hours during which the undertakers might have access to their street boxes. The Board of Trade thought it undesirable to specify in a provisional order, which can only be altered by a further provisional order, the precise details of construction in the case of works necessary to the supply of energy, and they were of opinion that the provisions already inserted in the order give the local authority ample power to control the construction of works in the public streets, and the hours during which the undertakers should have access to their street boxes. The remaining alterations were not, the Board of Trade understand, considered important by the Board of Works.

Digitized by Google

The views of the Board of Trade were communicated to the local authority, who, as the Board of Trade are informed by the promoters, on May 22, passed a resolution rescinding the resolution of October 10, 1894, above referred to. A resolution was also proposed at the same meeting to rescind the resolution of April 10 set out above, but was not carried.

(2) *Windermere District Electric Lighting Order*, 1895.—The Windermere and District Electricity Supply Company, Limited, applied for a provisional order in respect of the districts or portions of the districts of the following local authorities—viz, the Windermere Urban District Council, the Ulverston Urban District Council, the Ulverston Rural District Council, the Bowness Urban District Council, the Grasmere Urban District Council, the Grange Urban District Council, the South Westmorland Rural District Council, the Ambleside Urban District Council, and the Corporation of Kendal. The promoters were unable to produce the consent of the last two local authorities, or to advance reasons sufficient to justify the Board of Trade in dispensing with such consent, and the Board of Trade omitted the districts of these local authorities from the area of supply under the order. The promoters on January 14 last entered into agreements with the Ulverston Urban District Council, the Ulverston Rural District Council, and the Grange Urban Council District with respect, amongst other things, to the purchase of the distributing mains and apparatus of the undertakers in these districts at the expiration of a period of 10 years from the commencement of the order, and in the case of the Ulverston Urban District Council the consent to the grant of the order was given, subject to the condition that the agreement should be incorporated in and form part of the order. The Ulverston Rural District Council and the Grange Urban District Council subsequently requested that the agreement might be specifically referred to in the purchase clause, and on the Board of Trade not being prepared to incorporate the agreement in the order a similar request was preferred by the Ulverston Urban District Council. The Board of Trade, while willing to give the local authorities powers, with the consent of the Board, to purchase the distributing mains, etc, considered that it was not expedient to refer to the agreement in the order. They communicated with the three local authorities concerned, one of whom—the Grange Urban District Council—still wished to have a reference to the agreement in the order; whilst the other two—the Ulverston Urban and Rural District Councils—asked that words should be added to the purchase clause to provide that any agreement already entered into shall be subject to such alterations as the Board of Trade, on consent being applied for, determine to be just and reasonable. The promoters, however, declined to accept the proposed addition, and the Board of Trade did not, therefore, feel justified in inserting it.

(3) *Liverpool Electric Lighting Order*, 1895.—In 1891 and 1892, the Liverpool Electric Supply Company, Limited, obtained provisional orders authorising the supply of electrical energy within a portion of the city of Liverpool; and, in the former year, they also obtained an order authorising the supply of energy within the adjoining district of Toxteth Park. The provisions of the orders relating to the two districts varied considerably. In December last the company applied for a provisional order, which proposed to repeal the existing orders and to re-enact the provisions of the Liverpool orders, with some modifications, making them applicable to the district of Toxteth Park, as well as to the portion of Liverpool. The Corporation of Liverpool have applied to the Local Government Board for a provisional order authorising the extension of the boundaries of the city so as to include the urban district of Toxteth Park, and the application is now under the consideration of that Board. The Urban District Council did not consent to the grant of the electric lighting order, but the Corporation of Liverpool (who will, if the Local Government Board order be confirmed, become the local authority for the Toxteth Park district in place of the Urban District Council) consented to the electric lighting order, and desired that it should be granted in the form in which it is scheduled to the confirming Bill. The Board of Trade, therefore, decided to grant the electric lighting order, with a proviso that it shall not have any force or effect unless the boundaries of the city of Liverpool are by a provisional order made by the Local Government Board, and confirmed by Parliament during the present session, extended so as to include the urban district of Toxteth Park. If the order of the Local Government Board is not confirmed this session, the electric lighting orders of 1891 and 1892 will remain in force.

LEGAL INTELLIGENCE.

THE SOUTHWARK BRIDGE EXPLOSIONS.

Before Judge Emden, sitting at Lambeth, on Tuesday, a case described by his Honour as one of considerable importance to the public, was tried, arising out of the explosions that occurred on February 1 last on Southwark Bridge. The plaintiff, James Price, was crossing the bridge about noon on the day mentioned when four explosions took place at different points on Southwark Bridge, the pavement being blown into the air, together with several persons, who sustained various injuries.

Mr. Lynden Bell, who appeared as counsel for the plaintiff, said this was a test case, and the claims of other persons depended upon its result. He called Major Cardew, R.E., an inspector of the Board of Trade, who had held an enquiry on February 4. He attributed the explosions to an accumulation of gas in the mains.

Mr. Hicklin, for the defendants, the South Metropolitan Gas Company, called **Mr. Livesey**, and other witnesses, who attributed the fracture to the excessive frost, which had hardened and expanded the earth above the pipe and increased the pressure upon it. They also alleged that the earth under the pipe had been moved by other parties who were laying adjoining pipes, and that the support of their pipe was thereby reduced.

His **Honour** considered that negligence had been established—first, in that the defendants had not discovered the fracture by the smell of the escaped gas, and also in not seeing that their pipes were left properly supported after other persons, to their knowledge, had been excavating and working around them. He gave judgment for the plaintiff—£12 damages, and costs on the higher scale, but with leave to appeal.

ALLEGED SMOKE NUISANCE.

Mr. Wm. R. Renshaw, as the responsible head of the Queen Anne's-mansions Lighting and Heating Works, St. James's Park, was summoned on Wednesday at the Westminster Police Court by the Westminster Vestry for permitting the issue of dense black smoke from a chimney, so as to be a nuisance.

Mr. Arthur Kent prosecuted for the Vestry, and stated that a furnace was employed to generate electricity, etc., for the whole of the mansions. In respect of the same sort of nuisance in July, 1893, a fine of £5 was imposed.

The **Defendant's Manager**, in extenuation, put it that the smoke from their own large chimney was no more than the aggregate from smaller chimneys of houses accommodating even fewer families than the mansions provided accommodation for.

Mr. De Rutzen: In other words, your defence is that the mansions are entitled to their volume of smoke proportionately to their inhabitants. It is the biggest and most unsightly block of buildings in London, but that it has a right to poison the surrounding locality is an argument that has no weight with me. There must be a fine of £5 and £5. 5s. costs.

COMPANIES' MEETINGS AND REPORTS.

INDIAN AND GENERAL INVESTMENT TRUST, LIMITED.

The seventh ordinary general meeting of this Company was held on Tuesday at Winchester House, Sir H. Seymour King, K C I.E, M.P., presiding.

The **Chairman**, in the course of his speech moving the adoption of the report and accounts, said: "I refer now to the loss made on an advance on Woodhouse and Rawson debentures. We made that advance—and I am bound to say we should make it again, given the circumstances—on debentures which had £480,000 of capital behind them. We advanced about 80 per cent. of those debentures, which were given in part purchase for property, therefore apparently adding safety and security to the debentures themselves Subsequently, out of an issue of about £185,000 of those debentures, £120,000 were converted into a 5½ per cent. debenture, ranking behind those who did not convert. Your directors thought it wiser to stay in front, and did not convert, and therefore we stood ultimately in the position of holding £12,000 of debentures out of £65,000 of a first mortgage charge, with £120,000 second charge behind us and £481,000 of share capital—in other words, £600,000 of money—so far as the accounts go, which were put forward by responsible men—as security, we thought, for our debentures. By an operation which I prefer not to characterise, £20,000 was put ahead of us by withdrawing certain securities over which we had only a floating charge, and giving a specific lien. I have my own opinions about transactions of that nature, and I think they are shared by most people who desire to support straightforward finance. At any rate, £20 000 was put ahead of us, and the result of the winding up and liquidation of that company has proved to be that the first debentures of all get 17s. in the pound, we get about 6s., and nobody else gets a halfpenny. In other words, about £30,000 now represents £685,000—the money that was subscribed in the City of London. I think, gentlemen, we may ask you to commiserate with us, and not to blame us, under the circumstances, for having made that loss. I attended a meeting the other day which was convened to consider whether we should sue the directors and try and get back some of this money. I would have voted gladly for any punishment that could have been inflicted upon them, but, after very careful consideration, I came to the conclusion that it would be throwing good money after bad, that although we might have a judgment, I was not at all sure that we should get more than the paper upon which it was written. So I thought we had better throw in our lot, take what we had got, and cut the loss."

ELECTRIC AND GENERAL INVESTMENT COMPANY, LIMITED.

Directors: George Herring, chairman; the Right Hon. Lord Cloncurry; J. B. Braithwaite, jun.; B. H. Van Tromp; Emile Garcke, managing director.

Report of the directors to be submitted to the sixth ordinary general meeting of the shareholders to be held at Winchester House, Old Broad-street, E.C. (hall No. 47), on Tuesday, July 2, 1895, at 3 p.m.

The directors beg to submit the balance-sheet and profit and

Digitized by Google

loss account for the year ended May 31, 1895. The profit and loss account shows a gross profit on the transactions of the year of £8,470. 17s. 1d., and after deducting all standing charges and the interim dividend already paid on the ordinary shares, there remains a net balance available for distribution of £5,330. 13s. The directors now recommend the payment out of the profits for the past year of a further dividend upon the capital paid up on the ordinary shares at the rate of 30 per cent. per annum for the past six months, and a dividend on the founders' shares of £20 per share for the year. This will leave a balance of £330. 13s., which the directors recommend should be added in equal moieties to the reserve funds of the holders of the ordinary and founders' shares. The trustees for the founders' shares reserve fund propose to distribute to the holders of such shares a sum of £15. 16s. per share out of the proceeds of investments sold and dividends received, making, with the before-mentioned dividend, a total distribution of £35. 16s. on each founder's share. The directors who retire this year are Lord Cloncurry and Mr. Braithwaite. The latter offers himself for re-election, but Lord Cloncurry permanently retires, on account of his continued residence in Ireland. The auditors, Messrs. Rait and Kearton, having dissolved partnership during the year, Mr. Rait was appointed by the Board to audit the accounts. He now retires, but offers himself for re election. It is proposed to make the dividends payable on July 3, 1895.

BALANCE-SHEET AT MAY 31, 1895.

Capital authorised—£200,000 in 39,900 ordinary shares of £5 each and 100 founders' shares of £5 each.			
Capital subscribed—20,000 ordinary shares and 100 founders' shares.			
Capital called up—			
£1 per share on 20,000 ordinary	20,000	0	9
£5 per share on 100 founders'	500	0	0
	20,500	0	0
Reserve fund—founders' shares—amount invested as *per contra* £9,274 0 3			
Ditto—dividends received and investments sold by trustees 1,584 2 8			
	10,858	2	11
Reserve fund—ordinary shares	10,318	0	7
Provision for contingencies	8,000	0	0
Loan account	26,790	0	0
Sundry creditors	1,431	2	8
Balance of profit and loss account	5,330	13	0
	£83,227	19	2

Note —There is a liability amounting to £8,516. 5s. in respect of calls that will become due on securities held by the Company.

Investments at cost	£69,821	8	2
Sundry debtors	1,924	15	5
Cash in hand and on current account at bankers	2,207	15	4

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Bucharest.—The Roumanian Ministry of Public Works invite tenders by June 29 for the concession of the building and working of a line of tramway in Bucharest. Preliminary security, 10,000f.

Medina del Campo.—The municipal authorities of Medina del Campo, Valladolid, Spain, invite tenders by June 27 next for the electric lighting of the town for a period of 20 years. Security, 5,000 pesetas.

Clevedon (Somerset).—Tenders are invited for the public lighting of their district every night in the year from sunset till midnight, for the Urban District Council. Tenders to be for one, two, or three years, and to be sent to Mr. Hy. C. Fry, clerk, Clevedon, by July 1.

Braila.—Tenders are invited by the municipal authorities of Braila, Roumania, by June 17 (29), for lighting the town by gas and electricity. Security required, 25,000f.—Tenders are also invited by June 17 (29) for the construction and working of electric tramways in Braila. Provisional security, 10,000f.

Harrow.—Tenders are invited by the Harrow Urban District Council for lighting their district. The specification may be seen and every information obtained on application to Mr. T. Charles, surveyor, High-street, Harrow. Tenders, endorsed "Tender for Public Lighting," to be sent to Mr. R. E. H. Fisher, clerk, Harrow, by 27th inst.

Motherwell (Scotland).—Tenders are invited by the District Committee of the Lanark County Council for the electric lighting of the new hospital being erected near Motherwell. Copy specifications and plans may be seen at the office of Mr. Alexander Cullen, architect, Motherwell. Sealed tenders, marked "Tender for Electric Light," to be lodged with Mr. J. F. Mackenzie, district clerk, County Buildings, Hamilton, by July 1.

Blackburn.—The Corporation of Blackburn invite tenders for the wiring of the town hall. Copies of the specification may be obtained from the engineer, Mr. E. M. Lacey, of 19, Old Queen-street, S.W., on payment of £1. 1s., which will be refunded on return of same accompanied by a bona fide tender. Plans may be seen at the office of the town clerk, or the engineer, from whom any further information can be obtained. Tenders must be sent in by July 13.

Preston. — Tenders are invited for the wiring and fittings required for the lighting by electricity of the Town Hall and public hall buildings. Specifications and conditions at the borough engineer's office, Town Hall, Preston, on payment of a deposit of £1, which will be returned on receipt of a bona fide tender. Separate sealed tenders for each of the buildings must be sent to Mr. Henry Hamer, town clerk, Town Hall, Preston, endorsed "Tenders for Electric Lighting," by 12 noon on July 1.

Inverness.—Tenders are invited for the following articles, among others, from July 1, 1895, to June 30, 1896, delivered free of all charges, viâ Dunkeld, at the company's storehouses, Inverness, for the Highland Railway Company: telegraph instruments and fittings and telegraph construction material. Forms of tender may be had on application to Mr. J. G. Bulmer, storekeeper, Inverness. Tenders, properly endorsed, sealed, and addressed to the directors, must be lodged with Mr. And Dougall, secretary, Inverness, by to-morrow.

Bedford.—The Electric Light Committee are prepared to receive tenders for the supply and erection of the following plant: Section A—Two water-tube boilers; Section B—two 140-b.h.p. double-acting compound enclosed engines; Section C—two 90-unit alternators with stationary armature. Specifications, with terms and conditions of tender and contract, may be obtained at the offices of Mr. T. G. Porter, clerk to the Urban Sanitary Authority, on payment of a fee of 7s. 6d. for each section. Tenders, sealed, and marked "Electric Lighting, Section A, B, or C," are to be delivered by Tuesday, 25th inst.

Bradford.—Tenders are invited for the supply of best gas coal, cobbles, nuts, and cannel, all to be well screened, dressed, and free from shale and pyrites, to be delivered at the several works of the Corporation in the borough during one year or two years, commencing August 1, for the Gas and Electricity Supply Committee. Form of tender, with any further information required, may be had on application to Mr. Wood, gas engineer, Town Hall. Sealed tenders, endorsed "Tender for Coal," to be sent to Mr. W. T. McGowen, town clerk, Town Hall, Bradford, by July 3. An assurance must be given by each contractor that he pays to the workmen employed by him not less than the minimum standard rate of wages.

Birkenhead.—Tenders are invited by the Corporation for the erection and completion of the engine and boiler house and other buildings, walls, etc. (the chimney excepted), in connection with the proposed electrical generating station at Bentinck-street, Birkenhead. Plans, specifications, and particulars, with the form of contract, can be seen, and (upon deposit of £2. 2s., which will be repaid upon receipt by the Corporation of a bona fide tender) bills of quantities, with form of tender, can be obtained on application at the Town Clerk's Office, Town Hall, Birkenhead, or at the office of Mr. James N. Shoolbred, M.I C.E., Albany-buildings, 47, Victoria-street, London, S.W. Tenders, which must be on the prescribed form, sealed and endorsed "Tender for Electrical Generating Station," must reach Mr. Alfred Gill, town clerk, Town Hall, Birkenhead, by noon on 27th inst.

Madrid.—The Spanish Postal and Telegraphic Administration invites tenders by June 28 for the supply of 20 tons of copper. Preliminary security 5 per cent., definitive security 10 per cent., maximum price 520 pesetas per ton. Conditions, etc., and forms of tender from La Direccion General de Correos y Telégrafos, Madrid.—The Spanish Postal and Telegraphic Administration invites tenders by June 29 for the supply of 40,000 white and 10,000 grey porcelain insulators. Maximum price, 1 peseta 5 centesimos for the white and 1 peseta 10 centesimos for the grey. Provisional security, 2,650 pesetas; definitive, 10 per cent. of the estimate. Tenders are also invited by June 30 for the supply of 25,000 zinc cylinders for Calland elements. Maximum price, 980 pesetas per 1,000; provisional security, 1,225 pesetas; definitive, 10 per cent. of the estimate. Conditions and forms of tender from La Direccion General de Correos y Telégrafos, Madrid.

St. Helens.—The Electric Lighting Committee of the Corporation are prepared to receive tenders for the supply and erection of the following plant: Section A—boiler-house plant, including boilers and fittings, forced-draught apparatus, feed pumps, etc.; Section B—engine-house plant, including steam alternators, oil-filter, fittings, etc., steam, exhaust, feed, blow-off, and sundry pipes, valves, and water-tanks, etc.; Section C—main switch-board and instruments; Section D—underground work, including cables, junction-boxes, culverts, and trenching; Section E—trans-

Digitized by Google

formers and fittings; Section F—meters; Section G—overhead crane. Tenderers are at liberty to tender for any section or sections, or for the whole of the sections, but not for part of a section. The ground plan of plant, plan of streets, etc., and specification, with terms and conditions of tender and contract, may be obtained at the offices of Mr. Robert Hammond, the consulting engineer to the Corporation, Ormond House, Great Trinity-lane, London, E.C., on and after June 11, on payment of £2 2s., which sum will be returned on receipt of a bona fide tender. Tenders, sealed, and marked "Tender for Electric Lighting," must be addressed to the town clerk at the Town Hall, St. Helens, and be delivered on or before Tuesday, July 2.

RESULTS OF TENDERS.

Worcester.—The tender of Messrs. Graham and Biddle, London, for wiring the Victoria Institute has been accepted by the Corporation. The amount is £768.

Burton-on-Trent.—The Town Council have accepted the tender of the Telegraph Manufacturing Company, Helsby, for supply of the iron piping for the high and low pressure cables for the extension of the electric light system across the Burton Bridge and along Ashby and Alexandra roads.

Hanley.—The Town Council have accepted the following tenders: E. Danks, Oldbury, two boilers and appurtenances for the electric lighting works, £1,178; W. R. Renshaw and Co., Cliffe Vale Works, Stoke, water-tank, etc., £164. 18s.; and S. Z. de Ferranti, switchboard, etc., £252. 10s.

Brighton.—The Corporation have received the following tenders for the supply and delivery at Brighton of 80 cast-iron and drawn-steel bracket posts for suspending electric light arc lamps:

Pierson and Co., 124, Fenchurch-street, London	£3,680
Newton, Chambers, and Co., Limited, Sheffield	2,640
Hart, Son, Peard and Co., Limited, Birmingham (accepted)	2,600

BUSINESS NOTES.

Western and Brazilian Telegraph Company.—For the past week the receipts were £2,389.

Transvaal.—At the New Comet mine the electric lighting installation is now in working order.

Ipswich.—The Town Council have postponed the question of applying for a provisional electric lighting order.

Stettin Electricity Works.—The Stettiner Elektricitätswerke pay a dividend of 6 per cent. for 1894, against 5½ per cent. in 1893.

Beckenham.—The Urban District Council have received a letter from the Crystal Palace District Electric Supply Company notifying a reduction of the company's charges for the supply of electricity.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 16th inst. amounted to £1,268, as compared with £882 in the corresponding week of last year, being an increase of £386.

County of London and Brush Provincial Electric Lighting Company, Limited.—An instalment of £2 per share becomes due on 29th inst. on the first issue of 10,000 6 per cent. cumulative preference £10 shares.

Fleetwood.—The District Council have held a meeting at which it was resolved that the correspondence from the Brush Electrical Engineering Company, Limited, with reference to the question of electric lighting in the district, be referred to the clerk for reply.

Ayr.—Mr. Hammond, the consulting engineer in connection with the electric light station, at a meeting of the Town Council reported that the current would be available on September 1. The cost of the extension of the cables outside the compulsory area was £990. 12s. 4d.

Madras Electric Tramways Company.—On the petition of the Commercial and Land Mortgage Bank for the winding up of this Company, counsel stated that the debt had been paid, and asked for leave to withdraw the petition. Mr. Justice Romer sanctioned the withdrawal.

W. T. Henley's Telegraph Works Company, Limited.—At an ordinary general meeting of this Company, held on Friday last, an interim dividend of 6s. per share, free of income tax, was declared on the ordinary shares of this Company, payable on August 1, 1895.

Walthamstow.—The Examiners of Standing Orders of the House of Lords have reported that the Provisional Order Bill for enabling the Walthamstow District Council to undertake the lighting of the district by electricity is in compliance with the standing orders.

Indo-European Telegraph Company, Limited.—This Company is prepared to receive, at its chief office, 18, Old Broad-street, on and after July 1 next, applications for the sixth series of coupons to be issued to holders of share warrants to bearer in this country. The application must be made on the printed forms provided for the purpose.

Christchurch.—A meeting of the Town Council has been held, at which the clerk reported that a scheme for lighting the town by electricity had been brought before the Roads Committee. Alderman Lane proposed that the Council should consider the question in committee, and that Mr. Burt be requested to attend the meeting.

City and South London Railway.—The returns for the week ended June 16 were £862, compared with £831 for the corresponding period of 1894, being an increase of £31. The total receipts for the current period of the present half-year are £22,299 against £21,755 in the corresponding period of 1894, an increase of £544.

Lambeth.—The Vestry at their last meeting resumed the consideration of the letter from Mr. Sidney Morse, offering, on behalf of the County of London Brush Provincial Electric Lighting Company, to take over, conditionally, the Vestry's provisional electric lighting order. After some discussion, it was decided to refer the matter to the Lighting Committee.

Heilmann System.—The Société Industrielle des Moteurs Electriques et à Vapeur, which exploits the Heilmann electric railway system, and has received an order from the French Western Railway Company for two electric locomotives, has been reconstructed. The old style of the company is retained, and the capital has been fixed at 4,000,000f., or £160,000.

Buxton.—A meeting of the Urban District Council has been held, at which it was reported that the Council in committee had received a letter from Messrs. Parsons and Co. It was resolved that the clerk write for information on the question of the transfer of electric lighting powers to the town clerks of Scarborough, Cambridge, and Newcastle.

Edinburgh.—The Lord Provost's Committee of the Edinburgh Town Council have agreed to recommend the Council's approval of the Electric Light Committee's report, which proposes to extend the high-tension mains to the Royal, Regent, and Carlton terraces, to the south back of Canongate, George-square, and the south side of the city, at a probable cost of £5,000.

Crompton and Co., Limited.—In Chancery, Mr. Justice Romer has sanctioned a petition for the reduction of the capital of this Company by a sum of £20,000, the reduction to be effected by the cancellation of 4,000 ordinary fully paid-up shares, that amount having been lost, or being unrepresented by available assets. Counsel said that the original capital of the Company was £300,000.

St. Pancras.—The Finance Committee of the London County Council on Tuesday reported that the St. Pancras Vestry loan of £14,300 for electric lighting purposes had been completed, and that the solicitor had been directed to hand the mortgage deeds to the Corporate Property Committee. The Vestry have decided to postpone the election of a chief electrical engineer for a fortnight. The candidates are Messrs. S. W. Baynes, B. Deakin, and H. R. J. Burstall.

Cramp Manganese Bronze Company of Great Britain, Limited.—This Company has been registered, with a capital of £50,000, to adopt and carry into effect an agreement, the parties to which are not named, and to carry on the business of manufacturers and workers of and dealers in bronze and other metals, or metallic alloys; also as metallurgists, miners and smelters, civil, electrical, marine, and mechanical engineers, etc., in all or any of their respective branches.

Coventry.—A local paper states that it will become necessary to dismantle a very large engine at the electric lighting works, owing to defects having been discovered in the foundations of the stonework on which the machinery stands. The matter is a somewhat serious one, because of the importance of an engine of the size of that fixed there resting on a secure bottom, but it is only fair to state that the building contractor is not held responsible for the defects which necessitate a portion of the work being done over again.

Whitehaven.—At a meeting of the Whitehaven Rural District Council the Water and Lighting Committee reported that the engineer has submitted plans of the proposed extension of the electric light station, and it was resolved to leave the matter in the hands of a sub-committee. The engineer reported that the two new engines and dynamos at the central station were completed on 27th ult. and were working. New mains for private lighting have been laid in Lower Queen's-street, Coates-lane, and Roper-street.

Change of Address.—The County of London and Brush Provincial Electric Lighting Company, Limited, inform us that they removed to Moorgate-court, Moorgate-place, London, E.C. Messrs. Clayton and Shuttleworth inform us that, on and after June 24, their London office and showrooms will be at 95, Queen Victoria-street, where they will exhibit motors for thrashing, electric lighting, sawing, pumping, and general purposes, comprising portable and fixed steam-engines, patent oil and gas engines (in motion), and other articles.

Manchester.—A meeting of the Town Council has been held, at which Mr. Alderman Higginbottom moved the adoption of the proceedings of the Gas Committee. He said that the tender of Mr. B. Goodfellow for eight pairs of compound condensing engines for the sum of £12,440, the tender of the Electric Lighting Construction Company for eight dynamo-electric machines for the sum of £7,381, and of Messrs. Heaton and Son for five Lancashire boilers for the sum of £5,371 had been accepted, in accordance, in each case, with the resolution of the Council.

Appointment Vacant.—The Streets Committee of the City Commissioners are about to appoint a working mechanic at a weekly wage of 30s. for their electrical laboratory. Applications, stating age, details of training, and experience, must be addressed to Mr. H. Montague Bates, principal clerk, Guildhall, and delivered, together with copies of not more than three recent testimonials, by 12 noon on July 2. Applicants must have had experience in electrical work, and specially in the handling, fixing, and adjusting of

Digitized by Google

meters. Preference will be given to candidates with a knowledge of the work of an electrical testing-room.

Dewsbury.—A meeting of the Town Council has been held, at which Alderman Robinson, in moving the confirmation of the minutes of the Lighting and Water Committee, said the Council would no doubt be pleased to notice that, notwithstanding the fact that the electrical energy sold was 846 units for the two weeks ending May 11, the quantity of gas distributed was in excess by 90,000 cubic feet for the same period last year, and that the quantity for the succeeding fortnight was nearly 500 000 cubic feet more than for the corresponding period of last year.

Liverpool.—The Midland Railway Company have erected a very large warehouse at the Sandon Dock. The warehouse and yard, including the adjoining cotton quay and offices, are illuminated by the electric light, the plant for which comprises three horizontal two cylinder engines by Messrs. Davey, Paxman and Co, Colchester. Two of these have cylinders 12in. and 14in. stroke and 28ft. flywheels, each driving a Thomson-Houston 50 arc light dynamo, and there is one smaller engine with cylinders 9½in and 12in. stroke, driving a 30 unit Edi-Hopkinson dynamos for office lighting, etc.

Tramway Fares.—Evidence of the desire of the Board of Trade to co-operate with Mr. A. C. Morton in his endeavour to prevent the raising of tram fares on Sundays and public holidays is contained in two Provisional Order Bills now before the House of Lords. The orders confirmed by these measures relate to the Somerton, Keinton-Mandeville, and Castle Cary Tramways, the Hartlepools Tramways, the Hartlepools Electric Tramways, the Newcastle upon-Tyne Corporation Tramways, the Wigan and District Tramways, the Gloucester Tramways, and the London United Tramways; and in every case a clause has been inserted prohibiting the practice against which the member for Peterborough protests.

Islington.—The vestry clerk at a meeting of the Vestry read a communication from the Board of Trade, giving a provisional approval to the system of electric lighting adopted by the Vestry. He stated that he had received a copy of the regulations which the Board of Trade proposed to issue for the protection of the public. One clause was highly objectionable It was to the effect that all conduits and receptacles should be so constructed as to prevent an influx of gas from the adjacent soil. If that were passed, the Vestry would be at the mercy of gas companies, instead of requiring gas companies to prevent the escape of gas from their mains into electric lighting conduits. On the motion of Mr. Chamberlayne, the regulations were referred to the Electric Lighting Committee, with power to act.

Dispute at the Edison and Swan Works.—Under the auspices of the Electrical Trades Union a meeting of trade unionists was held at Ponders End on Saturday in support of the men, women, and boys on strike at the Ponders End Works of the Edison and Swan United Electric Light Company. Mr. G. W. Montague (president of the Electrical Trades Union) occupied the chair, and said they had to thank Sir Charles Dilke for calling the attention of the Government to the fact that the firm, although engaged on Government work, was not paying the trade union prices, contrary to the conditions of the contract. He believed the matter would be taken up in the House of Commons, and by that means the duration of the strike would be materially lessened. He expected the strike would last only a few days longer.

Harrogate.—A meeting of the Town Council has been held, at which the General Purposes Committee stated that the Electric Lighting Sub-Committee reported, as to electric lighting plant, that the borough surveyor laid before them an account as to what had been done as to buildings and plant preparatory to carrying out the electric lighting order. The town clerk reported that, as instructed by the sub-committee, he had invited Mr. Robert Hammond, consulting engineer, to meet them and Mr. Wilkinson, the electrical engineer, with a view, before carrying out the scheme which had been adopted by the Council, of having the whole reconsidered as to the system, the site, and the area of supply. Mr. Hammond attended the committee, and undertook to examine what had been done, and to report upon the whole scheme, and the Mayor, the chairman of the committee, and Alderman Ward, were appointed as a sub-committee to confer with him thereon. It was resolved that the report be approved and adopted. Mr. Hammond has promised to report as soon as he possibly can.

Telephones for the Fire Brigade.—The Fire Brigade Committee of the London County Council, on Tuesday, reported that the Council recently sanctioned the establishment of telephonic communication between the Watling-street station and five places in the City where firemen are on duty by day as well as by night. The chief officer now asks that similar communication may be established between the Bishopsgate station and the watch boxes in Eastcheap and Finsbury-circus, at which firemen are also on duty by day and night, and that the fire alarms near such boxes may be dispensed with. The Post Office is prepared to maintain these lines of communication for £16 a year. As, however, annual charges amounting to £15 for the fire alarms will shortly cease the increased annual cost will be only £1. The committee recommended that telephonic communication should be established between the Bishopsgate fire-engine station and the fire-escape and hose-cart stations in Eastcheap and Finsbury-circus, the existing fire alarms near such street stations to be dispensed with.

Twickenham.—A meeting of the District Council has been held, at which the clerk read the report of Mr. Collin Brodie, the expert who was commissioned by the Council to report on the instruments offered for the working of the fire calls by Messrs. Harrison and Coles, and Mr. Stuart. In this, Mr. Brodie stated that in his opinion Messrs. Harrison's magneto-apparatus was not suitable for the purpose for which it was intended, and that, on the whole, Mr. Stuart's tender was the best, and should be accepted. Mr. Webb asked if Mr. Brodie had had all the correspondence? The Clerk: Everything. Mr. Messom said that after hearing that report he should move that Mr. Stuart's tender be accepted subject to the amendments suggested in the report. Mr. Beard seconded, who said they could not act otherwise after having the experience of the expert. Mr. Buller asked if the property owners could object to having a line of telegraph posts in their neighbourhood. Mr Laffan said he had no doubt that they could get the wayleaves, and then posts would not be necessary. The motion was carried.

Derby.—The Markets Committee of the Town Council on Thursday last week inspected the electric lighting of the Derby Market Hall. Mr. Butterworth (deputy-chairman), accompanied by a representative committee and the borough surveyor (Mr. R J. Harrison) met the contractors, Messrs. John Davis and Son, of All Saints' Works, at 9 p.m., when the electric light was switched on. The arc lamps in the interior of the hall number six, taking 20 amperes each. The approaches are also lighted by arc lamps. Each stall and shop is provided with its own incandescent lamps. There are approximately 400 incandescent lamps throughout the buildings. The committee much appreciated the general lighting arrangements, and were exceedingly interested in the elaborate switchboard which controls the various circuits, six in number. The arrangement has been very carefully thought out. Each group of lamps is provided with a safety cut-out on each main. Each section of lighting is again provided with a safety cut-out which is again repeated on the main switchboard, so that should any short-circuit occur in any individual lamp only a very small section of lighting is temporarily extinguished. The meters are so arranged that the current being consumed by any of the various sections may be ascertained at a glance.

Leeds.—The Yorkshire House-to-House Electricity Company, Limited, are about to further reduce their price for electricity. The new scale of charges comes into operation on July 1, when the maximum gross price will be 6d. per unit. This is reduced to 5¾d. per unit in the case of consumers of not less than 1,500 units per quarter, and to 5½d. per unit when the consumption for the quarter exceeds 3,000 units. A scale of discounts is also announced, the benefits of which are available equally to the smallest and largest consumers, the discounts being calculated upon the consumption per lamp. A consumer using his lamps not less than 300 hours in the quarter is entitled to a discount of 5 per cent., and for a greater number of hours' use the discount increases up to a maximum of 15 per cent. An additional discount of 5 per cent. is allowed in all cases for prompt payment. Under the new scale the minimum net price is slightly under 4½d. per unit, whilst the greatest price payable by any consumer is just under 5¾d. per unit. Leeds will thus have the benefit of one of the cheapest supplies of electric light in the country. For heating, cooking, and motive power the company are supplying current at 3d. per unit. The use of electricity for these purposes is steadily extending. The number of lamps now connected to the mains is about 28,000, compared with 11,500 a year ago.

The Epping Forest Railway.—On the 13th inst. the London, Walthamstow, and Epping Forest Railway Bill came before a Select Committee of the House of Commons, presided over by Sir C. Dalrymple. Mr. Arnold Statham, who represented the promoters, stated that the object of the Bill was to improve the engineering clauses of the Act of last year, which was passed in order to relieve the congested areas north and east of Liverpool-street, and to enable the workmen of that large industrial area to reach Epping Forest to escape from the vitiated atmosphere in which they worked during the day, and to obtain cheaper dwellings than they could get in and about London. The financial prospects of the scheme had improved since last year, inasmuch as satisfactory arrangements had been made with the Midland Railway Company, by which they would carry passengers over the new line, and the present Bill was required for the formation of junctions with the Tottenham and Forest Gate and the Tottenham and Hampstead lines. All the petitioners against the Bill had been satisfied, including the County Council on the question of workmen's trains and fares, and, as a result, the alternative Bill for the abandonment of the line would be withdrawn. Mr. W. Beswick Myers, one of the engineers, gave evidence in support of the Bill, and the committee declared the preamble proved.

Pembroke (Ireland).—Mr. Clifton Robinson, managing director of the Dublin Southern District Tramway Company, and Mr. Little have waited on the Pembroke Township Commissioners to discuss certain minor differences between the Commissioners and the company as to the building of the electric tramway. Mr. Robinson said the work on the tramway in the whole Blackrock section was now within measurable distance of completion. They had been assured by the contractors that the road could be ready and open for inspection on July 3 next. The directors desired him to assure the Commissioners that they were perfectly ready and anxious to carry out the work in conformity with their order and their Act, and to meet the requirements of the Board in every way. With regard to the present state of Northumberland-road, they had opened it before they should in order to convenience the people connected with the show, and consequently it was not in the condition it should be. Of course, until the company put the road in perfect condition, the Board of Trade inspector would not pass it for public traffic. The company hoped to be able to give them a street railway which would be second to

Digitized by Google

none in its progressive character. Nothing in the world had ever been built of the kind which had cost so much money as this line. After the deputation had withdrawn the clerk was given directions to act in the matter as the Board's solicitor might advise.

Liverpool Electric Supply Company. — An extraordinary general meeting of the Liverpool Electric Supply Company, Limited, is to be held on the 22nd inst. for the purpose of considering and (if thought fit) passing the undermentioned resolutions: "(1) That the agreement now submitted to the meeting, dated May 28, 1895, entered into between the Company of the one part and the mayor, aldermen, and citizens of the city of Liverpool (hereinafter called the Corporation) of the other part for the sale of the undertaking of the Company to the Corporation be approved, subject to such alterations as Parliament may see fit to make therein. (2) That the Company do apply to Parliament in the present session for an Act to make all necessary and usual provisions for effectuating such sale, for the distribution of the price thereof and the assets of the Company, and for the eventual winding up and dissolution of the Company, and that the directors be instructed to take all necessary steps for obtaining such Act. (3) To determine the provision to be made in such Act or otherwise for the appropriation and distribution of the reserve and renewal fund of the Company and the payments to be made to the directors and any officers and servants of the Company in recognition of their services. (4) That the Bill for the Act now submitted to the meeting be approved, subject to such additions, alterations, and variations as Parliament may think fit to make therein." Should the resolutions be passed by the required majority they will be submitted for confirmation as special resolutions to a second extraordinary meeting, which will be subsequently convened.

New Mains, etc., in London.—The report of the Highways Committee of the London County Council on Tuesday stated that the Council on May 28 formally disapproved of the works referred to in a notice of the County of London and Brush Provincial Electric Lighting Company, under the Wandsworth Order, 1892 owing to the details being insufficient. Further details had now been supplied, and the committee recommended that sanction should be given. The committee also approved of an application from the Metropolitan Electric Supply Company to lay low-pressure concentric cables from the stage entrance of Drury-lane Theatre along the south side of Russell-street, the east side of Catherine-street, and the south side of Exeter-street to the Gaiety Theatre; and from the Notting Hill Electric Light Company to lay mains and to construct street boxes in Addison-crescent, in and across Addison-road, and in and across Kensington Park-road. A notice was received from the Vestry of Hampstead of intention to lay mains in Haverstock-hill, and in West Heath-road, Branch-hill, Frognall-rise, and Holly Bush-hill. The Vestry was the undertaker under the order, and the Council had no power of approval or disapproval of these works. Sanction was given for the House-to-House Electric Supply Company to lay mains on the north and west sides of Cornwall-mansions; for the Kensington and Knightsbridge Lighting Company to lay mains in Ovington-square; for the Westminster Electric Supply Corporation to lay mains on the north-east side of Upper Tachbrook-street; and for the Charing Cross and Strand Electricity Supply Corporation to lay mains across Panton-street.

Southport.—At the last meeting of the Town Council the Electricity Committee reported that they had held a meeting at which a report was read from Mr. Arthur Ellis, borough electrical engineer, upon the advantage which would accrue to the Corporation and consumers by the adoption of Wright's maximum-demand indicator, a system which has been adopted at Brighton and other places. The sub-committee recommended (*a*) that the principle of charging for electric current adopted in Brighton should be adopted in Southport; (*b*) that 7d. per unit should be charged for 365 hours on the maximum demand for electrical current during the half-year, that beyond that number of hours the charge should be at the rate of 4d. per unit; (*c*) that these charges should come into force on July 1 next; (*d*) and that the tariff should not apply to public street lighting. The committee resolved that the recommendation be adopted. Councillor Hesford, in moving the adoption of the minutes of the Elec tricity Committee, made reference to the above report. He gave a lengthy description of the maximum-demand meter by which the current would be measured. There were several modes of arriving at the charges to be made, but the one proposed was the one of the greatest excellence and with fewest faults. The mode was applicable to a consumer with one lamp or a thousand. The object of the resolutions to which he had referred was to increase the number of consumers of the electric light. It looked a great drop, but it would have the useful effect of encouraging consumers to take more light. Councillor Todd seconded the minutes, which were adopted after some discussion.

Telegraph Material for Central Africa.—There is being shipped in Glasgow Harbour, on board the steamer "Isle of Dursey," 250 miles of telegraph material, weighing over 400 tons, destined for Blantyre, Central Africa. There it will be used in the construction of Mr. Cecil Rhodes's telegraph line from Cape Town to Uganda. Southward from Blantyre the line has been practically completed, with the exception of a short stretch through Portuguese territory which intervenes in the district of the Zambesi. This portion will, however, be soon completed, when telegrams will be transmissible from Britain to Blantyre without interruption. The projected extension to the north, for which the material is now being shipped, will proceed from Blantyre by Lake Nyassa to Karonga, and thence to Abercorn, at the southern extremity of Lake Tanganyika, from which the line will pass along the western side of that waterway. The material is being taken out for the African Trans-Continental Company by the African Lakes Corporation of Glasgow, who have undertaken to deliver it at Chikwawa, which is situated on the Upper Shire, in British Central Africa. The ocean steamer "Isle of Dursey" will run alongside the African Lakes Corporation's floating hulk "Britannia," which is moored off Chinde, at the mouth of the Zambesi River. The telegraph material will be placed on board the "Britannia," whence it will be discharged into the corporation's stern-wheel steamers, and by this means conveyed along the Zambesi and the Shire Rivers. The telegraph posts are lightly made of steel, as wooden poles would soon be destroyed by the white ants which infest the district.

Bristol Tramways.—The new electric tramway between Bristol and Kingswood is rapidly approaching completion. The cars to St. George were taken off last week, and in their places 'buses are now being used to carry passengers, so that the work of reconstructing the line between the city and St. George's Church may not be interfered with. The same day as the cars ceased running workmen began to pull up the old rails and to relay the heavier and newer pattern ones. Unless the unforeseen happen, the relaying of the old line will be completed by the middle of July, when it is expected that the section between St. George's Church and Kingswood Church will be finished, the electrical apparatus fixed, and the new cars—the trucks of which have come from America—will be put together and in readiness for public use. The date of the opening of the line has not yet been fixed, nor can it be until the work is a little further advanced. The matter was alluded to at the meeting of the Bristol Sanitary Committee in connection with a memorial from the inhabitants of Old Market-street, who regard the present as a favourable time for the relaying of the thoroughfare with wood blocks, and the removal of the cab-stand and other structures which are alleged to disfigure the locality. The petition, however, is not likely to cause any delay to the tramway company's work for the committee have already selected the streets upon which money they have specially raised for wood paving shall be used, and Old Market-street is not included, and they cannot add to the list. The committee, however, sanctioned the laying of an additional track at the city end of Old Market-street, on condition of the lines on the east of Captain Carey's-lane being retained in their present positions.

Stafford.—The Electric Lighting Committee at the Town Council meeting recommended that the electric light mains should be extended from Greengate-street along St. Mary's-churchyard to Victoria-square, along Foregate-street to the general infirmary (in case the trustees of that institution decided to apply for the electric light), from the public baths to the junction of Newport and Lichfield roads, and from Greengate-street along St. Mary's-gate. Alderman W. H. Peach, in moving the adoption of the report, informed the Council that Mr. Lovatt had practically completed his contract for the buildings at the electric light station, and the boilers were also in a forward state. The committee found it advisable to somewhat restrict the contract for laying the mains from the idea originally proposed on account of the expense that would be incurred. With regard to the question of obtaining access to the works from the north side, the committee decided to leave the matter with the vice-chairman and himself. In company with Mr. Bell, they had had an interview with Messrs. Bostock, and after a long conversation they agreed to let the Corporation have a space of land by the side of their factory and 20ft. from the corner of the central station for £25, which would give all that was needed in the way of entrance. Alderman Silvester seconded the proposition. Mr. Smallman asked whether there was any cause for delay in the laying of the mains, because he noticed several of the workmen were walking about the streets. Alderman W. H. Peach replied that the reason was not apparent, but the men were certainly not remaining idle at the expense of the Corporation, the work being done by contract. He added that the committee hoped to be able to turn on the electric light during August at the latest.

Blackrock (Ireland).—A meeting of the Town Commissioners has been held, at which Mr. James Sweeney wrote complaining of the manner in which the tramway company were erecting the posts to carry the overhead electric wires. He stated they were erecting some of the posts in the middle of the footpaths, so that a person was in danger of striking up against them at night, and even in the daytime persons had to step out on the road. Mr. Goodbody said that he had called the attention of the Board to the subject at the last meeting and was told that the posts were not more than 4½in. from the side of the footpaths, but he found that the distance was 14in. He considered the position of the posts most objectionable; they should be placed close to the wall or at the edge. Mr. Hartigan said that they could not be placed close to the wall, as there was to be some ornamental castings placed at the base of the posts. The letter was referred to the engineer. The Township Secretary informed the Board that the tramway company had stopped running their cars between Blackrock and Kingstown, and the company were about to commence cutting up the road for the purpose of laying the electric tram line on that section. Mr. Goodbody said the company ought not to be allowed to move a single paving stone until they finished the section between Dublin and Blackrock. Mr. Canning proposed that the township engineer, Mr. Kough, C E, be instructed not to allow the tramway company to open the roads on the Kingstown section until the main street—Dublin section—was completed. Mr. Goodbody seconded the motion. The Chairman said that was the best way to meet the difficulty. Mr. Marchbanks said that they should not take any steps to prevent the company from proceeding with what

Digitized by Google

he would call the grand work of laying the electric line through the township, which would be a great improvement. Mr. Kelly thought the best way to deal with the matter was to approach the tramway company in a friendly manner. The Chairman said that a committee had charge of the matter, and he would advise them to see the company that very day, or they might commence to open up the road at once. After some further discussion, the motion was withdrawn and the matter left in the hands of the committee.

Woodhouse and Rawson.—A meeting of the debenture holders in Woodhouse and Rawson, Limited, was held on the 13th inst. at Cannon-street Hotel, for the purpose of deciding whether their funds should be employed in taking action against the directors and auditors of the Company for the recovery of certain moneys which, in counsel's opinion, they were liable to refund. After discussion, the 10 per cent. debenture-holders decided unanimously against instituting legal proceedings, and the 6 per cent. debenture-holders voted in the same way by a majority of £32 650 stock to £3,900. The decision of the 5½ per cent. debenture-holders was postponed until Wednesday last, when they met at the official receiver's office, 33, Carey-street. Mr. C. J. Stewart, official receiver and liquidator presided and reported that at the former meeting held at Cannon-street Hotel, the 10 per cent debenture holders and a majority of the 6 per cent. debenture-holders voted against the institution of the proposed proceedings. Those two classes of creditors, however, expected to receive substantial dividends, but in the case of the 5½ per cent. debenture-holders there was no prospect of anything whatever in the shape of dividend, and the questions to consider were: (1) whether the proposed legal proceedings against the directors, etc., should be instituted; and (2) whether some arrangement could be made with the other classes of debenture-holders whereby the 5½ per cent. class would derive some benefit. He asked the meeting to regard the situation simply from a commercial standpoint, and to put away any vindictive feeling that might be felt against the directors. A resolution in favour of the proposed proceedings was moved, seconded, and discussed at some length, but upon a vote being taken it was declared to have been lost by a large majority.

Hanley.—A special meeting of the Town Council was held on Tuesday, when the Mayor (Alderman E. J. Hammersley), Mr. W. J. Carruthers-Wain (chairman of the North Staffordshire Tramways Company), Mr. W. H. Scott (general manager of the company), and Mr S. Sellon (electrical engineer) attended as a deputation to lay before the Council the views of the tramway company as to electric traction. A letter was received from Mr. J. G. B. Elliott, secretary to the tramways company, stating that the company had under consideration the adoption of some improved form of traction, and the directors were of opinion that the only form suitable for the district in which their lines were laid was that of electric traction by means of overhead wires. They desired, in the first instance, simply to obtain the consent of the local authority to the general principle, as they were assured that if reasonable conditions could be arranged with the local authorities the necessarily considerable amount of capital required would be available. The Corporation would appreciate the importance of the step to the company, inasmuch as it would involve the entire re-equipment of the line with cars and motors, and the provision of an expensive plant, but it was practically certain that no difficulties would arise as to the payment of interest and provision of sinking fund for the capital required to be raised, provided that some arrangements could be made with the Corporation in regard to the power of purchase of the lines in their district, which power they would be able to exercise in about seven years from new. The directors, having regard to the advantages of electric traction, were preparing a comprehensive scheme for extensions of their lines, including lines from Trent Vale to the London-road, Stoke, Newcastle to Hanley, Longport to Burslem, Goldenhill, and Tunstall to Burslem, and Smallthorne to Burslem. The Corporation would appreciate the fact that those lines, acting as feeders to the main line, would enable the whole system to be worked at a more moderate rate than if the main line were alone worked, and it was that, amongst other reasons, which induced the directors to have confidence in the success of the undertaking generally. He was desired to add that arrangements similar to those suggested in that letter had already been made in other towns where steam was being replaced by electricity—namely, Coventry, and West and East Hartlepool—and that with the Corporations an arrangement had been made whereby they had the power to purchase the generating station, plant, and equipment, with a reasonable allowance for depreciation, should they desire to purchase. The subject was fully discussed in committee, and afterwards a resolution was adopted approving generally of the company's scheme. The Local Government Board have notified the Council that they have sanctioned the raising of a loan of £5,000 for the purposes of electric lighting.

Milnrow.—A meeting of the Milnrow and Newhey District Council has been held, at which, in accordance with notice given at a previous meeting, Councillor Dawson moved: "That it is most desirable that this Council take into consideration the adoption of electric light supply works and maintenance for supplying the district with electric light, and, further, that application be made to the Board of Trade for a provisional order to erect and complete the same." Mr. Dawson said that at the meeting of the General Purposes Committee held in March last, among other accounts submitted he noticed one from the Milnrow Gas Company amounting to £191. 8s. On enquiry he learned that this was for the half-year ending February, and for gas supplied to 187 street lamps. He then stated that a considerable saving might be effected by the adoption of the electric light, and one or two members suggested that it would be advisable to obtain information on the matter. He undertook to get that information—of course, in his private capacity—and that night he proposed to explain detailed information which he had obtained, and which, in his opinion, justified the statement he made to the committee. He then read to the meeting a return of the present cost of lighting the district. Proceeding to refer to the electric light, he said that during the progress of his enquiries for information he found that previous to 1890 the bulk of the electric light supply was in the hands of private companies, the percentage being six private companies to one public body. In 1894, however, the order of things was reversed. The local authorities—seeing how profitable the business was—then took the lead, the percentage being 10 to 1. The Board of Trade fixed a maximum price of 8d. per unit for the light supplied to the public. The average annual consumption of units per light was 14, and this—at 8d. per unit—meant 9s. 4d. per year per light. He maintained that that was the poor man's light, because it was far cheaper than gas. He had prepared for their consideration four schemes, and he suggested that the best course to adopt would be to appoint a committee of three members from each ward, with the chairman as an ex-officio member, to consider the question. The Chairman said they all ought to thank Mr. Dawson for the large amount of information he had given them. He quite agreed that they should have a committee, but he thought that the latter part of the resolution with regard to applying for a provisional order would commit them to something. The Clerk thought it would be best if the committee considered the question before an application for a provisional order was made. Councillor Dawson said the Council were not bound to do anything even if they got a provisional order. However, he was quite willing that a committee should enquire into the matter first. Councillor Lamb seconded the resolution that a committee should be appointed (Councillor Dawson altering the original resolution so as to omit the latter part), and the proposal was unanimously assented to. A committee of nine members (three from each ward), with the chairman as an ex-officio member, was then appointed.

Walsall.—The Town Council have held a meeting, at which the following letter was read from the chairman of the South Staffordshire Tramway Company: "Your letter of May 14, addressed to the manager, containing a copy of a resolution passed at the quarterly meeting of your Council on May 13 was duly forwarded to me. Its consideration by the Board of this company has been somewhat delayed owing to my absence from England. It was, however, considered to-day by the directors, and I have to inform you that our manager has already been instructed to ascertain the views of other local authorities through whose district the cars run, as the arrangement of the seats of the cars was, I understand, approved by all the local authorities affected before they were constructed. Another difficulty is that the cars do not belong to us, and the owners (the Electric Construction Company) do not seem inclined to immediately make any alteration, because of the temporary nature of our agreement with them, and which we obtained, as you will remember, only by the kind offices of his Worship the Mayor of Walsall and yourself. You will, however, be pleased to hear that we hope in a short time to conclude a satisfactory and permanent agreement with the Electric Construction Company, and before your next quarterly meeting I hope to be able to inform you that the seats of the cars are in course of alteration. The present directors are, of course, in no way responsible for the arrangement of the seats, nor do they think such an arrangement should ever have been attempted, as it is a physical impossibility to comfortably seat three people abreast and provide a gangway inside a car which is to run on a 3ft. 6in. gauge. With regard to the overcrowding of the cars, instructions have already been given to the manager to increase the service, and with regard to the overcrowding, particularly on Saturday nights, I have given instructions that this should be carefully looked into, and that, if possible, more cars should be run at the hours the overcrowding occurs. If you have any information on this point, I shall esteem it a favour if you would be good enough to send it on to me, as the company has always received such consideration from the authorities of Walsall that I can assure you, on behalf of the Board, that it is their desire to comply with the wishes of the Walsall authorities and public in every way they possibly can."

Leeds Tramways.—The Sub-Highways (Tramways) Committee of the Leeds Corporation finally considered their report on haulage on Friday last, and having adopted it, and also the report of the city engineer, ordered copies of both to be sent to the members of the Highways Committee. The committee find that the difference in annual cost between the cable system of haulage and the overhead electric system, combined with a conduit in the centre of the city, will be £13,880 in favour of electricity. They also point out "that, whilst they are of opinion that the electric overhead system has passed the experimental stage, its possible advantages have doubtless not yet reached the maximum." They believe that electricity, in some form, will be the motive power of future tramways, and not only will the capital expenditure upon overhead electric traction be much smaller than upon the cable system, but in case of any alteration, or the subsequent adoption of a new method of electric traction, less loss would result in its adoption than would be sustained by a change from cable haulage to another system. Having regard to the many routes in Leeds, and to the great length of each, involving varying requirements as to frequency of service, the committee are unanimously of

Digitized by Google

opinion that electric traction is the most suitable for the tramways of the city. Their recommendation to the Highways Committee is to this effect. A special meeting of that body for the consideration of their reports is to be held on Monday, the 24th inst., and should the documents be adopted, a copy will then be forwarded to each member of the City Council, with a view to the question of haulage being finally settled. The city engineer was recently asked to report as to the cost of providing an electric conduit for the centre of the city—say, to the dispensary in North-street the junction of Hunslet-lane with Hunslet New-road, the end of Queen-street, in Wellington street, and the top of Park-row—and to state the advantage of, and objections to, such conduit As the tramways are a double track in each of these lengths, the total length of electric conduit required would (says Mr. Hewson) be 2 77 miles. He computes that total additional capital required for the substitution would be £10,183, and taking all the *pros* and *cons*. into account, he thinks that a penny, or a little over, per car mile, would represent the excess of cost of running the conduit system over the electric overhead system. He therefore puts the total approximate extra annual cost of electric conduit over electric overhead for the above-mentioned central portions of the track at £2,230. The difficulties and objections to the electric conduit system are, he says, an occasional stoppage of the cars through short-circuiting, brought about by adventitious matter finding its way into the conduit; a wide slot, dangerous to narrow wheels, unless an improvement on the Budapest system is made; frequent obstruction of the traffic of the most crowded streets of the city by taking them up for the repair of the electrical portion of the conduit. He adds, that unless very effective automatic machinery can be made to do the work, there will necessarily be, with a service so frequent as 1½ minutes, an interference with the traffic in passing the cars from one system to another, and there would be 10 of such changing places.

Worcester.—The Electricity Committee recommended the City Council at its last meeting to fix the following charges for electric arc lamps for street-lighting: all-night lamps £25, and half-night lamps £15. 10s. per annum. In moving the adoption of the recommendation, the Deputy-Mayor said that brought the charge down to an average of £20. 5s., and was a reduction on the charge which the committee made in the first place of £74 a year. When the committee went fully into the matter, and had information from a great many other districts, they found, considering that they had water power, that they would be justified in making such a low charge as that proposed. The maximum charge for arc lamps ismilar to those at Worcester was £45, and the lowest was £20. Alderman Holland seconded. Mr. Rushton said six gas lamps had been taken away between the Cathedral and Pump-street, and four electric lamps put in their place. They would cost £100 a year, as against £18 a year for the gas The recommendation was adopted. A resolution was passed, on the recommendation of the Electricity Committee, agreeing to remove at three months' notice, and to make good damage done to the property, an incandescent electric light bracket which Alderman Ernest Day had allowed to be erected on the corner of his house 22, Pump street, and the Deputy-Mayor thanked Alderman Day for agreeing to the proposal. A question was asked by Mr. Rushton as to an account of £72. 19s. 7d. from Messrs. Underwood for coal. Last month there was an account for £104. 10s 3d. He asked whether the present account was for the monthly supply of coal at the generating station. Mr. Williamson explained that the coal was supplied by Messrs. Underwood on the order of the late engineer of the electrical works without any instructions from the committee, and the committee refused to pay for the coal until they wanted to use it. The firm had had to wait for six months for their money. The City Engineer (Mr. Caink) disputed the deputy-mayor's statement, and said he ordered no coal without the authority of the committee. The coal was sent without any order from him, and that was the reason the committee very properly refused to pay. Mr. Williamson promised to submit a report as to the consumption of coal at the generating station at the next meeting. The payment of the account was authorised. Mr. Charge referred to an account of £2,000 to be paid to the Brush Electrical Engineering Company as the eighth instalment on account of the contract for laying mains, etc., and asked whether this was limited to the contract, or whether the committee had power to go beyond the contract and pay for any extras that might be incurred without the sanction of the Council? The Deputy-Mayor said he took it that they had no power to pay anything without the sanction of the Council. Mr. Millington said the Council had sanctioned works by the Brush Company amounting to £27,059—£23 109 being for mains, £1,861 for street-lighting, and £2 089 for waterworks pumping. If the Council passed the present bill they would have paid £23,560, so they were well within the mark The Town Clerk, upon the terms of a resolution passed last September, and referred to by Mr. Charge, said the chairman of the committee would be justified in signing anything certified by the engineer for payment. The Library and Museum Committee recommended the acceptance of the amended tender of the New British Installation Contractors, at £786, for wiring the Victoria Institute for the electric light. Mr. Chaplin moved the adoption of the recommendation. Alderman Buck moved that the tender of Messrs. Graham and Biddle, London, at £768, be accepted. He said he thought the committee had made a mistake in allowing one of the parties who tendered to correct an error in the way they did. It was most important that the Council should at once correct that error, not only to deal fairly with Messrs. Graham and Biddle, but for the future, because if the recommendation was adopted he could hardly anticipate that any people outside would tender for any work the Council might have to do. It was perfectly consistent, if a man found he had made a mistake to allow him to withdraw his tender, but he did not understand on what ground they could allow him to amend it. Mr. Lewis seconded. On a division the amendment was carried by 13 votes to 12.

Taunton—A meeting of the Town Council has been held, at which the Electric Lighting Committee reported that the cable of No. 1 circuit had been laid underground and all the posts and overhead wires removed. Also that a report had been received from Dr. Fleming, in which he stated: "In accordance with your request, I visited Taunton on May 8 and made an inspection of the electric lighting station and of the new work carried out this last year in connection with the establishment of the second transformer sub-station and the laying of the mains connected with it. I found the supply station in good working order and the whole of the plant carefully looked after. I inspected the second sub-station, and found the work there had been carried out in a thoroughly workmanlike manner. Two 30 kilowatt transformers are now in operation in this second station supplying by the underground system of distributing mains connected to it. A considerable section of the arc-lighting lines has also been put underground, and this work has been carried out in accordance with certain special requirements of the electrical adviser of the Board of Trade The whole of this cable work has been carried out by Messrs. Fowler, Waring, and Co., in a satisfactory manner under the superintendence of your borough surveyor and electrical engineer. I may remark, in passing, that in laying these mains and selecting a system of underground conductors for use at Taunton I have avoided the use of all junction-boxes and open conduits, in which gas could accumulate I decided to employ triple-concentric cable sheathed with lead and covered with steel plate. The whole of the distributing mains and the house connections are laid without any junction-boxes or open spaces in which gas could accumulate, and there need, therefore, be no apprehension on this point. The two sub-stations, Nos. 1 and 2, are now in excellent working order. I am anxious that a trial of the demand-meter system, invented by Mr. Wright, of Brighton, should be given at Taunton. I have next to consider in what direction further extensions should take place. I do not think that at the present moment the demand for light in East-street justifies you in putting down a third sub-station, although this will ultimately have to be done. There are three matters which ought to take precedence of this. In the first place, it is essential to remodel the switchboard in the station. It is necessary that the engineer in charge should now be able to switch any machine on to any circuit instantly and without danger, and that as the demand for current gets less, the whole of the circuits may be gathered together on to the small machine. The present switchboard, I consider, is not properly provided with instruments to enable this to be done with ease and certainty. I suggest therefore to you that an invitation to tender should be put out for a station switchboard in accordance with the specification which I send with this on a separate sheet. In the next place, I want to draw your attention to the fact that at the present moment the demand for light fully fills up the capacity of the present plant. The lamps installed are at the present moment 2 100; this load can only just be taken on one of the large machines and a small one. If in the course of next winter an extension of 500 or 600 lights takes place—and which we may assume will be the case, having regard to the rate of progress during last winter—then the station would be left without proper reserve plant. It will be necessary therefore for you to consider very soon obtaining a tender for a fourth engine and alternator. I have considered carefully what form this should take. An economy in space would result from the employment of a direct-driven alternator, and there would be no objection to the employment of this method of driving, since each machine is necessarily independent. I suggest, therefore, the tenders for the supply of this alternator and engine should be invited, but that those who tender for the alternator should have the option of either driving it by belt or direct. I have considered whether it is possible to extend the private lighting by laying a short underground high-tension cable to the Crescent. If, as I understand, there is some considerable quantity of private lighting to be obtained in this part. then I think that a high-tension cable, 7-16th in size, should be laid down, and a service should be given to house transformers placed in this part if promises of consumption can be obtained. It is very desirable to supplement the shop-lighting by as much private lighting as possible, because the private lighting continues farther into the night. I therefore advise that a canvass should be made, and that information should be obtained whether any number of consumers can be obtained in the Crescent. Also that your borough and electrical engineers should report to you what it would cost to lay down a 7-16th high-tension cable from the No. 1 sub station along the Corporation street and Crescent, and give a supply by house transformers where required. It is necessary to take all possible steps to push the private house-lighting as the tendency of the shop-lighting is towards shorter hours. Your street arc lighting is so good that the shops along the route of the arc lights take advantage of it to illuminate their shop fronts, and do not use their incandescent lamps as much as they would do if there were no arc lighting. The new Board of Trade regulations are intended to be more stringent as regards the use of high-tension private arc lamps, and it will be at no distant date necessary to provide all the private arc lighting off the incandescent lighting circuits, or, better still, to encourage the use of high candle-power incandescent lamps for the purpose. In addition to this, the new rules require that each street arc lamp should be capable of being separately extinguished and cut out of circuit. Mr. Couzens has devised a switch for this

Digitized by Google

purpose which, it seems to me, deserves a trial. I recommend that six of these switches be procured and fitted at once to six street arc lamps, and if proved satisfactory after three months, the whole of the street lamps must be so fitted." On the motion of Councillor Potter, seconded by Alderman Trump, the report of the committee was adopted. Councillor Webber said that he saw in the special report all the elements of a large expenditure in the future. He took exception to one part of Dr. Fleming's report – viz., that although they had borrowed £5,000 to extend the light, the residents in East reach were to be neglected, whilst a solitary place like the Crescent was to be looked after because three members of the Lighting Committee lived there. The Mayor pointed out that they were not then asked to adopt Mr. Fleming's report. Councillor Potter said the committee had no intention of departing from the decision to put additional arc lamps in East-reach. It was the private lighting that Dr. Fleming referred to, as it would not pay them to put down a sub-station until the private lighting increased. The speaker said he felt bound to mention that Dr. Fleming expressed to the committee his great satisfaction at the way in which all the plant was kept at the depôt. Colonel Hasted, when he held the enquiry at Taunton, also said he never saw a place of the sort kept in a better condition. The Mayor mentioned that he met Dr. Fleming for the first time a few days previous, and he much struck with him and considered they were fortunate in having such an adviser.

PROVISIONAL PATENTS, 1895.

JUNE 10.

11355. **Improvements in or connected with electric cables.** Henry Edmunds, 47, Lincoln's-inn-fields, London.

JUNE 11.

11358. **Improvements in electric switches.** Edward Jesse Piper, 34, Victoria-street, Westminster.

11375. **A covering for electric wires.** Franklin Streater Randall and John Shallcross, 70, Wellington-street, Glasgow. (Complete specification.)

11399. **Arc lamp.** Samuel Pleasants Parmly, 46, Lincoln's-inn-fields, London. (Complete specification.)

11414. **Improvements in and relating to soundless voice-conveyors for telephones.** Walter William Scott, Prince's-chambers, Wolverhampton,

11434. **Improvements in telephony.** Charles Adams-Randall, 1, The Avenue, Bedford Park, London.

JUNE 12.

11449. **An improved grip to be employed in laying electric cables.** Robert Middlemass, Peasholme House, Scarborough.

11478. **Improvements in apparatus for the electrolytical separation of precious metals from their ores or other materials containing them.** James Yate Johnson, 47, Lincoln's-inn-fields, London. (Louis Pelatan, France; and Fabrizio Clerici, Italy.) (Complete specification.)

11482. **Improvements in automatic repetition on telegraph, cable, and other lines.** Herbert Arnaud Taylor and Joseph Arthur Lovel Dearlove, 24, Southampton buildings, Chancery-lane, London.

JUNE 13.

11516. **Improvements in fittings for electric lamps.** Charles Hopkinson, 17, St. Ann's-square, Manchester.

11528. **Improvements in and relating to insulators for electrical purposes.** Alfred James Perton Whitaker and Frederick Gwilym Treharne, 45, Southampton-buildings, Chancery-lane, London.

11540. **Improved electric primer.** The Morris Tube Ammunition and Safety Range Company, Limited, and Arthur James Herney Wyatt, 28, Southampton-buildings, Chancery-lane, London. (Complete specification.)

11544. **Improvements in the manufacture of the insulator arms of telegraph poles and poles for carrying conductors of electricity generally.** Bullers, Limited, and Edward John Chambers, 7, Staple-inn, London.

11547. **Improvements in and connected with apparatus for coating strips, wire, and like metal articles by electro-deposition.** The Cowper-Coles Galvanising Syndicate, Limited, Sherard Osborn Cowper-Coles, and William Pole Routh, 47, Lincoln's-inn-fields, London.

11548. **Improvements in telephone systems.** John Edward Kingsbury, 24, Southampton-buildings, Chancery-lane, London. (The Western Electric Company, United States.)

11549. **Improvements in telephone systems.** John Edward Kingsbury, 24, Southampton-buildings, Chancery-lane, London. (The Western Electric Company, United States.)

11555. **Improved means for opening and closing doors by electricity.** Solomon Cambie, 76, Chancery-lane, London.

11558. **Tee junction pipe clips for electric mains and services.** Ernest Mercer and John James Glass, 166, Fleet-street, London.

11560. **Improvements in or connected with electric mains or conductors.** James George Willcox Aldridge, 40, Chancery-lane, London.

JUNE 14.

11594. **Improvements in telephone receiver fittings.** Max Binswanger and Francis George Bell, 73, St. Stephen's-road, Upton Park, London.

11633. **Improvements in or connected with ceiling roses, lampholders, and other electrical fittings.** Charles William Rea Campbell, 54, Fleet-street, London.

11641. **Improvements in electrical alarums.** Henry Laville and Joseph Plisnier, 97, Newgate street, London.

JUNE 15.

11659. **Improvements in elements for secondary batteries.** Job Thomas Niblett, 20, Devonshire-road, Greenwich, London.

11672. **The positive and negative lightning conductor.** James George Vine, 14, Glen Eagle road, Streatham, London.

11700. **Improvements in alternating-current machines.** Walter Claud Johnson and Louis John Steele, 28, Southampton-buildings, Chancery-lane, London.

NOTES.

Institution of Electrical Engineers.—The conversazione of the Institution will be held in the galleries of the Royal Institution of Painters in Water Colours, 191, Piccadilly, W., on Wednesday evening, July 3, from 9 to 12 o'clock.

Electric Train-Lighting.—The lighting of certain trains on the Marienburg-Mlavka Railway by means of accumulators has given satisfaction, and the directors have, therefore, resolved to electrically light all their trains. The storage batteries used are those of the Kölner Akkumulatorenfabrik Gottfried Hagen, of Kalk, Cologne.

"Thomsistas."—This peculiar word has been invented by a Spanish writer in *El Telegrafista Español* in an article in which he advocates the establishment in Madrid of a practical school for the purpose of teaching students the working of the Thomson receiving instrument. It seems that such an *escuela de thomsistas* already exists in Cadiz.

Electrozone Plant.—The Philadelphia (U.S.A.) Board of Health have determined to instal an electrical plant for the manufacture of electrozone according to Mr. A. E. Woolf's process. The plant, with a capacity of 1,000 gallons per hour, will be placed in the basement of the Municipal Buildings, and the product will be used for sprinkling the streets and for general disinfecting purposes.

New Budapest Electric Railway Scheme.—Herr Ludwig Schiller, director of the Budapest-Neupest-Rakospalota Electric Railway, and Prof. Carl Zipernowsky, director of the electrotechnical department of Messrs. Ganz and Co., have requested from the Hungarian Ministry of Trade and the municipal authorities of Budapest a concession for the construction of a metropolitan electric railway in that city.

Municipalisation and Nationalisation of Telephones.—Upon the expiry of the concession which was accorded to the Bell Company, the municipal authorities of Amsterdam have decided to take the working of the city telephones into their own hands. The concession expires shortly. It is also worthy of note that the Austrian Government has made arrangements to take over the Vienna telephone lines of the Privat-Telegraphengesellschaft.

Electrical Journalism.—On June 11 notice was given by the authorities of Somerset House that the Electricity and Electrical Engineering Newspaper Company, Limited, had been struck off the register and dissolved. This, of course, does not in any way affect the present position of our contemporary, the entire undertaking having been purchased from the company by Mr. S. Rentell, A.I.E.E., more than 18 months ago, and successfully carried on by him ever since.

Amalgamation of Zinc Plates.—The *Elektrochemische Zeitschrift* gives the following method of amalgamating battery zincs: To a saturated solution of neutral sulphate of mercury are added sufficient sulphuric acid to completely dissolve the mercury, and oxalic acid, the result being a liquid of the consistency of cream, then a little sal-ammoniac. The zinc plates are immersed in the mixture and afterwards vigorously rubbed. If they are not immediately used they should be carefully dried.

North-East Coast Institution.—We have received parts 7 and 8 of vol. xi. of the *Transactions* of the North-East Coast Institution of Engineers and Shipbuilders, which contains the reports of the adjourned discussion on Mr. Henry Foster's paper on "The Application of the Electric Arc to Machinery and Boiler Repairs"; of the adjourned discussion on Mr. S. O. Kendall's paper on "Turret-Deck Cargo Steamers"; and a paper on "The Metric System of Weights and Measures," by Mr. G. H. Baines, with discussion.

The Pacific Cable.—A Reuter's telegram from Brisbane states that, in opening Parliament, Sir H. W. Norman, the governor, in his speech on the occasion, said that the Pacific cable question is receiving the most earnest consideration, and should the researches of the proposed joint commission of Great Britain, Canada, and Australia justify it, and should the other Australian colonies show further hesitation, Queensland would be prepared to recommend that the Pacific cable be constructed by Great Britain, Canada, and Queensland alone.

The Electric Light in St. Petersburg.—Two further streets in St. Petersburg, the Millionnaya and the Moskva-Pereulok, are to be lighted by electricity. The work is to be carried out by the firm Goné and Co., representatives of the Allgemeine Elektricitäts-Gesellschaft, of Berlin. The 800-ampere dynamos will be driven by two Marshall engines, steam for which will be supplied by water-tube boilers. The 1,200-c.p. arc lamps will be suspended from wires fastened to the houses on each side of the thoroughfares, in order to avoid the shadows cast by poles.

Northern Society of Electrical Engineers.—We have received the *Proceedings* of this society for the past year. The contents include a paper on the "Blackpool Electricity Works," by Mr. John Hesketh, with discussion "Notes on Designing a System of Underground Electric Light Mains," by Mr. John H. Rider, with discussion "Electricity Meters," by Mr. R. P. Wilson, with discussion "Lighting Installations," by Mr. H. A. Henderson, with discussion; "The Commercial Possibilities of Accumulators for Tramcar Traction Considered as a Municipa Undertaking," by Mr. Alfred H. Gibbings, with discussion.

The Reaction of the Armature Current in Continuous-Current Dynamos.—This was the title of a paper which Herr W. Lahmeyer read before a recent meeting of the Frankfort Elektrotechnische Gesellschaft. He succeeded, he said, in 1888, in entirely obviating the reaction of the armature current in his dynamos. It had even become possible, by means of new methods, both in continuous and alternating current machines, to cause the armature current to assist the magnetism of the dynamo. The author detailed, in conclusion, how a continuous-current dynamo could be made with no winding at all on the fixed magnets. This dynamo, however, was more original than practical.

Extraordinary Resuscitation.—A New York telegram, dated 21st inst., ran: "To-day, at Rochester, New York, an employé of an electric company, named Frank Grover, aged 33, accidentally received an electric discharge of between two and three thousand volts, or nearly three times the force considered necessary for the electrocution of condemned criminals. For fully three-quarters of an hour he lay apparently dead, with his right leg and arms terribly burnt. Finally, however, after 90 minutes' exertion by a physician and three of Grover's fellow-workmen, he was sufficiently restored to be transferred to his home." It is to be hoped that the statements made are more correct than is the English of the message.

Long-Distance Telephones.—It is stated that the telephonic communication established between London and Manchester, Glasgow, and other large centres will not be placed at the disposal of the general public before the middle of next month. A serious difficulty has arisen owing to induction. When the new trunk lines were tested

Digitized by Google

last Wednesday week the success of the experiments was due to the fact that only one or two circuits were being tried simultaneously, but when all the circuits are in operation the induction set up becomes very inconvenient. Everything that is possible will be done to minimise the difficulty, and an endeavour will be made to establish three offices in London for the despatch and receipt of long-distance messages.

Originality.—According to an American contemporary, it is proposed to do away with the smoke nuisance in Pittsburg by erecting at some convenient coal mine a mammoth electric power plant to furnish the city with current for electric lighting, heating, and power, thus entirely doing away with the burning of coal in and immediately about Pittsburg. We are informed that "it is thought by Mr. Robert Marshall, of the firm of Marshall Bros., elevator builders, the originator of the scheme, that electricity could be furnished from such a plant cheaper than power could be generated in isolated city plants." How any claim can be set up for Mr. Marshall as the originator of such a scheme it is difficult to understand. It is simply an adaptation of the proposal made long since by Mr. B. H. Thwaite, of Liverpool.

Scottish Institution of Engineers.—We are in receipt of the *Transactions* of the Institution of Engineers and Shipbuilders in Scotland, which contains a report of the annual general meeting held in April last, including a paper on "A New Departure in Steam-engine Economy, with a Description and Tests of Field's Combined Steam and Hot-Air Engine," by Prof. Andrew Jamieson, M.I.C.E., F.R.S.E.; the resumed discussion on Mr. W. Carlile Wallace's paper on "Electrical Transmission of Power in Shipyards and on Board Merchant Steamers"; and discussions on Mr. W. David Archer's "The Strength of Ships' Beams"; Mr. James M. Gale's "Extension of the Loch Katrine Waterworks"; and Mr. Archibald Denny's "The Drawing Office." Mr. W. D. Archer expressed his approval of introducing the electric light into drawing offices.

Recreation.—Prof. W. E. Ayrton and Mrs. Ayrton gave an "At Home" on Friday last, which was largely attended by the leading men in the electrical industry. We understand that many of the students at the Central Institution were also invited, and in this way got introduced to those who have made the industry what it is. The social side has never been neglected by Prof. Ayrton. We do not hold with these gentlemen that after-dinner speaking is more useful than good work done, but commend all attempts to bring the rising young men into touch with those who deservedly hold high positions in the profession. Among the guests present last Friday were Prof. A. B. W. Kennedy, F.R.S., Mr. J. W. Swan, Prof. G. Forbes, F.R.S., Prof. W. Crookes, F.R.S., Prof. O. Henrici, F.R.S., Prof. S. P. Thompson, F.R.S., Prof. J. Perry, F.R.S., Dr. W. Sumpner, Mr. F. H. Webb, etc.

The Hermite Process.—Dr. W. Hill Climo, brigade-surgeon, lieutenant-colonel, Army Medical Service, (retired), in dealing with the subject of "Malta Fever in Relation to Local Sanitary Conditions," writes that "as long as the harbours of Malta are allowed to continue in their present state there must always be sanitary risk and danger to the public health. Moreover, as these conditions are mainly caused by our own navy and by our mercantile marine, while they are not remedied, by what right can we impose sanitary obligations on the civil population? Certainly none. It is a case of putting our own house in order first. The proposal, then, is that the sewage, etc., of our ships should be disinfected and rendered innocuous before being poured into the harbours of Malta by the electrolysis of sea water. No better locality could be selected for the trial of the Hermite process than in those harbours and in the Suez Canal."

The Railway Congress.—The Prince of Wales on Wednesday opened, at the Imperial Institute, the International Railway Congress, which first met at Brussels in 1885, then at Milan in 1887, at Paris in 1889, and at St. Petersburg in 1892. For business purposes the congress will meet on Monday, July 1, and continue its sittings until July 9. The remainder of this week will be spent in visits to several important railway works, and various entertainments have been arranged for the guests. The Prince was received by Sir Andrew Fairbairn, a director of the Great Northern Railway and president of the English section; Lord Emlyn, deputy-chairman Great Western Railway, vice-president; the committee (consisting of the chairman, directors, and general managers of all the principal railways in the United Kingdom); Sir Courtenay Boyle, secretary of the Board of Trade, and other gentlemen interested in railway work.

New Telephone Transmitter.—Mr. C. F. Dunderdale, of Chicago, has recently brought out a type of telephone transmitter possessing some novel features. While recognising the good qualities of a granular carbon in a transmitter, the tendency to packing has to be avoided, and this he has secured by means of a constant rotation of the case containing the granules, so that the carbon granules are in a constant state of reversal of position, thus preventing their settling and the ensuing separation of the grains, the finer from the coarser, the former collecting at the bottom and the latter at the top, which the shaking only aggravated and increased the tendency to solidify. One of the means of accomplishing this result is to provide a lever and ratchet movement, the lever being the support hook of the receiver, the act of hanging up and taking down of which causes the rotation to be secured automatically. It is stated that every characteristic of the voice is preserved, whether the transmitter is shouted at or whispered into, all extra vibratory sounds or echoes being eliminated.

Iron and Steel Institute.—In view of the holding of the autumn meeting of the Iron and Steel Institute in Birmingham on August 20, 21, and 22, the South Staffordshire Ironmasters' Association have held a meeting in Birmingham for the purpose of making preliminary arrangements. Sir Benjamin Hingley, M.P., said it was 24 years since the institute had met in that district. He suggested that after the reading of scientific papers on the development of the trade and on other matters of interest to the general body of the members, they might visit some of the leading places in Birmingham and the neighbourhood. The Mayor of Birmingham had consented to welcome the members and to hold a reception in the Council House. Lord and Lady Warwick had promised to receive them on the second day, and Sir Arthur Hodgson and Mr. Edgar Flower would give them a hearty welcome to Stratford-on-Avon and open the Shakespearean Theatre. The Chairman concluded by moving that a general reception committee should be appointed. Mr. Arthur Keen seconded the motion, which was carried. The Chairman said that £1,000 would cover the expenses, and £760 was subscribed in the room.

Society of German Electrical Engineers.—At the third annual meeting of the Verband Deutscher Elektrotechniker, which is to be held in Munich on July 5-7 next, reports of commissions will be presented on: (1) "The Introduction of Uniform Sizes of Contacts and Screws"; (2) "The Avoidance of Misunderstandings in Tendering"; (3) "Safety Rules for Electrical Installations"; and the following papers will be read: "The

Digitized by Google

Dubiau Pumps," by Herr F. Ross; "The Munich Electricity Works," by Herr F. Uppenborn; "Comparative Studies of Acetylene, Gaslight, and the Electric Arc Light," by Dr. W. Wedding; "The Circuit Law," by Dr. K. Heinke; "Electrical Cooking Apparatus," by Herr Paul Stotz; "The Behaviour of Transformers under the Influence of Alternating Currents of Various Periodicities," by Dr. G. Rössler; "Electric Meters," by Herr G. Hummel; "Obtaining Electricity by Chemical and Thermo-chemical Methods," by Dr. O. Schmidt; "Equipotential Lines in Magnetised Plates," by Dr. von Lommel; and "The Distribution of Radiation Energy," by Dr. L. Grätz. On July 6 the municipal electricity works, and on July 7 the electrical installation at the Central Railway Station, will be visited.

Chesterfield and Midland Counties Institution of Engineers.—The annual general meeting of this institution, coupled with an excursion, will be held in the town of Warwick on Saturday, July 13, at 1 p.m. The party will assemble at the railway station, Coventry, on the arrival of train due 11.26 a.m., and will proceed in brakes, specially engaged, by road *viâ* Stoneleigh Abbey to Warwick. Immediately on arrival the general meeting will be held in the Court House, the use of which has been granted by the mayor, the Earl of Warwick. The election of officers for the year 1895-6 will be determined by scrutineers of the voting papers appointed by the meeting. New members elected by ballot will be announced. The general report of the council, and their finance report, with abstract of the audited accounts of the past year, will be presented for discussion and adoption. A printed copy will have been sent to each member. The president-elect (Mr Emerson Bainbridge) will deliver an address from the chair. The following paper will be read or taken as read: "Photometric Value of, and Notes upon, Various Illuminants Used in Mines," by Mr. A. H. Stokes. The limited time at disposal will not allow of discussion upon papers read at previous meetings, but members are invited to contribute communications thereon by letter. Luncheon at the Warwick Arms, 2.30 p.m.

Cheap Electricity in Germany!—A paragraph is going round the German daily papers to the effect that the Frankfort Electricity Works purpose supplying electrical energy at the price of six pfennige (¾d.) per 1,000 watt-hours. The *Elektrotechnischer Anzeiger* remarks that, to its knowledge, the cheapest electric power is that furnished by the Isar Works, near Munich, at 10 pfennige (1·2d.) per 1,000 watt-hours, but these works have the advantage of the water power of the Isar, and the German technical journal naturally throws doubt on the Frankfort announcement. A later number of the same bi-weekly technical journal, however, confirms the above-named price, which, nevertheless, applies only to current used for power purposes. The lessees of the Frankfort Electricity Works (Messrs. Brown, Boveri, and Co.) write: "The very low price offered of 6·5 pfennige per 1,000 watt-hours is based upon an extremely heavy yearly consumption, amounting to at least a million kilowatt-hours for, say, a 24 hours' run of a 150-h.p. motor. This price can be fixed because the demand on the central station chiefly occurs at times when there is not much other work doing, and when a heavier load on the machines favourably influences the running. By this consumption the working cost of the station per kilowatt-hour is substantially reduced, and this is a preliminary step towards cheapening the price of light."

Electric Meter Trials in Paris.—Particulars have been published in *Bulletin* No. 3, 1895, of the Association Amicale des Ingénieurs Electriciens de Paris, of a series of electric meter trials which were recently carried out by a commission, at the head of which were MM. E. Sartiaux and J. Laffargue. The experiments were confined to the meters used in the metropolis—namely, those on the Thomson, Aron, Frager, Brillié, and Déjardin systems. Observations kept on about 500 Thomson meters in service showed that there were 4½ per cent. of failures, of which 2 per cent. were due to dust on the disc, 1½ per cent. to loosening of the endless screw, and 1 per cent. to various causes—bad connections, burnt wires, etc. There were, moreover, several cases of faulty casings, which allowed dust to penetrate into the interior of the meter. The Aron meter, the commission state, requires great care in its construction and numerous precautions have to be taken in using it. Failures in this instrument have been to the extent of 15 per cent. The commission, nevertheless, say that the Aron meter has given very satisfactory results in Paris, but it has to be well looked after. The Frager meter presents many inconveniences. The Brillié instrument has yielded good results in practice, but it, too, necessitates much watching; its mechanism is very delicate, and of very small dimensions. The Déjardin meter, which is "a very simple machine," has been "working with regularity" in one of the Parisian districts. In concluding their report, the commission complain that makers have not exercised that care in turning out the later instruments which they used in producing the first meters for trial.

The Telephone Service.—In common, we presume, with other subscribers, says the *Financial Times*, we have received from the National Telephone Company the following minatory circular: "Notice to subscribers—It has been brought to the company's notice that in several cases subscribers are habitually allowing non-subscribers to use their instruments, and in other cases subscribers have received messages on behalf of non-subscribers, and sent their clerks out to deliver such messages. Such practices are not only a violation of the agreement enter into by the subscriber with the company, but also contravene the license of the Postmaster-General, under which subscribers are enabled to have exchange facilities, and the company have power under their agreement to cancel the contract of any subscriber who disregards the above-mentioned conditions. The company feel that it is only necessary to call its subscribers' attention to these irregularities to ensure their discontinuance in the future.—Wm. E. L. Gaine, general manager. Head Offices, Oxford-court, Cannon-street, E.C." As we have not been guilty of the criminal conduct referred to, our conscience is easy, but the occasion seems a suitable one for the issue of a circular which we have had in contemplation. Here it is: "Notice to the company—It is within our knowledge that in many cases subscribers are habitually unable to use their instruments owing to defects in the company's system, and to the arbitrary conduct of the operators. In other cases, and owing to the same causes, subscribers are continually receiving messages not intended for them, while the voice of the subscriber with whom they are supposed to be in communication is inaudible. Such a state of affairs is not only a violation of the understanding which leads one to become a subscriber, but also fully justifies the action of the Postmaster-General and others in trying to make some fresh arrangement which will ensure that subscribers shall have the exchange facilities they pay for. The subscribers have power to refuse to renew their contracts, and many of them would do so were it not that they hope for a better state of affairs as the result of the select committee's report. The subscribers would feel—were it not that experience has proved the contrary—that it would only be necessary to call the com-

Digitized by Google

pany's attention to the inefficiency of its service in order to secure its improvement in the future."

Personal.—Mr. John Gordon Longbottom, who has been appointed by the governors of the Glasgow and West of Scotland Technical College to the Lectureship in Mechanics in the college, is 25 years of age. He served an apprenticeship of six years in the various departments of the works of Messrs. F. and J. Butterfield and Co., Limited, engineers and machine tool makers, Keighley, during which time he was successful in the competition for Whitworth exhibitions (1889). By the aid of a national scholarship gained in 1890 he had a three years' course of training in science at the Royal College of Science, London, and at the final examinations of the session 1891-2 in the advanced courses of mechanics and machine design he was placed in the first position, being awarded the prize and first-class associateship of the college in mechanics. In 1893 he gained a Whitworth scholarship, being placed second on the list. He was also an associate member of the Institution of Mechanical Engineers. Amongst numerous certificates and medals held from the Science and Art Department there are first-class honours, certificates, and medals in machine construction and drawing; theoretical mechanics and first place in first-class honours applied mathematics in 1893; first-class certificates in mathematics, also honours certificates in practical, plane, and solid geometry, sound, light, and heat, etc. After winning the Whitworth scholarship, he attended the engineering courses at University College, London, and spent some considerable time in practical laboratory work, and at the final examination of the senior classes in the theory of elasticity and dynamics last session he was awarded the prize. During the year of his scholarship he made a special study of those higher branches of mechanics most useful from an engineer-point of view, such as advanced theory of elasticity, theory of arched ribs, metal domes, masonry and brickwork arches and domes, continuous beams, struts, theory and strength of cylindrical and spherical shells with especial application to guns, flues, and boilers, pressure of earthwork on supporting walls, etc. He also had experience as a demonstrator for Prof. Karl Pearson in his graphical courses in applied mathematics and mechanics.—An interview with Mr. James Clifton Robinson, A.I.C.E., A.M.I.E.E., the managing director of the London United Tramways Company, Limited, has appeared in the columns of the *West London News*.

The Apprentices' Institution.—The cause of technical education has in recent years been advocated on every platform as one on which the industrial and commercial welfare of the country in large measure depends. But it has been felt in the best-informed quarters, says the *Times*, that technical schools in the ordinary sense cannot meet all the requirements of the case. A boy or girl must first choose a trade, and then acquire the technical training suitable to that trade, as technical teaching at large would only lead to the proverbially dangerous smattering. There is, it is true, a superabundance of labour of all kinds seeking employment, but of really skilled artisans in the numerous trades which are not yet appreciably affected by machinery there is a scarcity rather than an over-supply, and there are some which are almost monopolised by foreigners. As a remedy for this state of things, and as a contribution towards the solution of the problem of the unemployed, it is proposed to establish an institution for the organisation and encouragement of the apprenticeship of boys and girls on leaving school. The scheme, of which Mr. J. Ballin is the secretary and one of the principal promoters, has met with the approval of a great number of eminent and experienced men, including Lord Rothschild, Sir John Lubbock, Sir S. Montagu, Sir J. Blundell Maple, Sir George Williams, Mr. Quintin Hogg, the Hon. W. N. Bruce, Sir Stuart Knill, Sir Richmond Cotton, Dr. Garnett, and the clerks to the Drapers', Mercers', Turners', Goldsmiths', Stationers', and other companies; and it is proposed to appoint a committee comprising a number of gentlemen with special and general knowledge of the subject. The institution will keep a register of employers and of applicants for apprenticeship. Preference will naturally be given to those trades which require the greatest skill and the teaching of which will take the longest time. Loans and grants of money will be made for the payment of premiums and the purchase of tools, and it is calculated that about £15 will suffice for each boy and £5 for each girl. Every precaution will be taken to prevent pauperisation, and in most cases the apprentice will be required to repay the advance by small weekly instalments out of his wages, though in cases of hardship in which it is specially difficult for parents to dispense with the earnings of their children, the conditions will be relaxed. It is anticipated that connection with a great institution such as it is hoped to establish, will have a steadying and elevating effect upon the young men and women whom it has benefited, and in furtherance of the scheme clubs will be established or assisted in suitable localities. The institution will also encourage the attendance of its *protégés* at evening classes for technical instruction, and make grants or loans for the payment of fees. One effect of the scheme will probably be to raise the standard of work and to increase the prosperity of masters in a comparatively small way of business; but by careful choice both of apprentices and masters, and the consequent provision of good training, it is hoped to provide the largest employers on the shortest notice with artisans on whom they can thoroughly depend, and certificates of efficiency will be awarded which will serve as an avenue to employment.

Conference on Technical Education.—A conference of representatives of technical instruction committees of county councils and of others interested in technical education was held on Thursday last week at the Society of Arts, John-street, Adelphi, for the purpose of affording an opportunity for the discussion of measures which the society have in view to enlarge the scope of their present action in the matter of examinations. According to a statement issued by the council of the society, there is a lack of a central organisation which might deal especially with such questions as the examination and inspection of classes. "In spite of the valuable work which has been done by the City and Guilds of London Institute, and by other bodies, it is only in a portion of the subjects sanctioned as subjects of technical instruction that examinations are held. The wide field of agriculture and home industries is untouched, while no means are provided for anything like a general system of inspection which local authorities may call to their aid should they desire to do so." Major-General Sir John Donnelly, chairman of the council of the Society of Arts, presided, and there were present Mr. W. Bousfield and Mr. Palmer, representing the City and Guilds of London Institute; Mrs. Maitland, Mr. Sinclair, and Mr. Laing, members of the London School Board; Mr. Snape, M.P., chairman of the Technical Instruction Committee of the Lancashire County Council, and a large number of prominent representatives of similar committees in other counties. The Chairman, in opening the proceedings, referred to the valuable work done by the Society of Arts in past years in initiating educational movements.

Digitized by Google

Among other things, the society established the technological examinations which were taken over by the City and Guilds of London Institute; and he wished to make it clear that the council of the society did not desire in any way to interfere with the examinations of the City and Guilds of London or any other similar body. There was a wide range of subjects, however, which other bodies had not yet touched; and it had been suggested that it was desirable to include these subjects in their system of examination. This would enable students to secure certificates, and technical inspectors would be provided to assist local councils in ascertaining whether their classes were being conducted on the right lines. His idea was that they should endeavour to establish a joint examining and inspecting Board formed of representatives of the present examining bodies and other authorities; but they had not yet got as far as that, and the object of the Society of Arts now was to ascertain the wishes and opinions of those who were interested in the matter. In order to open the discussion, he moved: "That it is desirable that the Society of Arts should extend its system of examinations, and provide for examination and inspection in those subjects which are not taken up by other bodies." Ultimately Mr. Reynolds, of Manchester, moved as an amendment: "That in the opinion of this meeting it is desirable that provision should be made for examination and inspection in the subjects of instruction undertaken by technical instruction committees but not at present included in the schemes of the Science and Art Department, the City and Guilds of London Institute, and the Society of Arts, and that with the object of giving effect to the same this conference recommends that a representative committee be appointed to draw up a report and prepare recommendations on the whole subject." Mr. Hodgson (Cumberland) seconded the amendment, and after some discussion it was agreed to and adopted as the substantive resolution. The proceedings then terminated.

A Submarine Post.—Mr. J. Henniker Heaton, M.P., in the *North American Review* says: "Two generations ago a heaven-sent genius took pity on the two great sister-nations of the Anglo-Saxon stock, dwelling isolated and apart, for ever sundered by the wild, tempestuous ocean. A slender wire was laid across the depths of the watery abyss, and an end of this wire was placed in the hand of either sister. 'Now speak,' said their benefactor, 'as if you were face to face. Share your joys, sympathise with each other's sorrows; take sweet counsel together; and if, as is the wont of your sex, you talk overmuch and overlong, why, you will be all the better friends." Why is it that this delightful vision has never been realised? If a man with a business of moderate dimensions corresponds with London customers by letter, knowing that his wealthy rivals habitually employ the cable for the same purpose, it is not because he prefers a week's delay, but because he cannot help himself. On the other hand, capitalists would be glad to have the rate 5dol. a word, in order to kill the competition of poorer men. Yet even rich men writhe a little in the grip of the cable companies; and this is why 97 per cent. of the messages are sent in code. The proportion of social messages exchanged between relatives and friends on matters of private concern—only 3 per cent.—is so small as to be hardly worth taking into account at all. The Atlantic cables are controlled by a monopoly; that is the evil to be dealt with. Strictly speaking, it is a duopoly, for there are two groups of shareholders interested; but these two maintain a common tariff, and so far as the public is concerned, all the evils of a monopoly exist. Unless competition be independent and unrestricted, its wholesome influence is non-existent. Let me here say, once for all, that I do not presume to censure the sagacious and energetic men of business who have laid the cables, and now work them. Some of these gentlemen—I refer, above all, to my friend Sir John Pender—have displayed financial and administrative talents of the highest order; and they cannot be blamed for monopolising electricity any more than others can be blamed for monopolising gas and water. The true culprits are the British and American Governments, which have allowed private persons to undertake State responsibilities and to intercept benefits that belong to the public at large. The communications of the people ought not to be at the mercy of a calculating director, who will naturally prefer a small number of messages at a high rate to a larger number at a lower rate. For such reasons the postal service in every civilised country is managed by State officials. But in every country the telegraph is superseding the post. The mere fact that an inland transaction can be arranged by telegraph or telephone in an hour, at any distance, as against 24 hours by post, causes a corresponding reduction in the time required for carrying out the bargain. Where, as in the case of Anglo American trade, the arrangement by post takes a fortnight, it is obvious that the bulk of such trade being conducted by post is handicapped with a fortnight's delay. The number of words sent over the cables between America and England last year was 23,000,000. Of these 20,000,000 were business messages at 1s. per word, and the balance, 3,000,000, were messages at 5d. per word. Deducting some small charges, the total income from Anglo-American cables may be put down at £1,000,000. Now, by means of the recent improvements, 45 words per minute can be sent over one wire, so that the 12 cables might be employed to send in one year no less than 283,824,000 words? It must be remembered, however, that only two of the 12 cables are extensively employed. Indeed, a cable expert of high authority is of opinion that the new cable of the Anglo-American Company, having a weight of 400lb. of copper to the mile, is of sufficient capacity to carry all the existing traffic. The cost of laying a Transatlantic cable is said to be about £500,000. If so, the total cost for the 12 working cables, and three which have been abandoned, is about £7,500,000. Yet the capital of a single company is £7,000,000, while for £1,000,000 we might at once lay two cables capable of doing all the work. The interest on £1,000,000 could not exceed £50,000, and the working expenses would be about £80,000; total, £130,000. For which annual expenditure the public might have a service just as good as the present one, for which it pays the companies £1,000,000. What I propose is that the British and American Governments should jointly acquire the property and rights of the existing cable companies at a fair valuation, and establish a common State monopoly in cable communication. They should then establish a tariff of 1d. per word; and the result would be a prodigious development of trade and an immense increase in the happiness of the masses. It is by no means impossible that ultimately the tariff might be still further lowered—down, in fact, to the lowest remunerative point. For governments have no right to make a profit out of the communications of the people. This programme is by no means a visionary one. For no appreciable increase of expenditure accompanies the augmentation of the traffic over a wire, which is almost pure profit. If the traffic increased twelve times under a penny tariff, the revenue would be the same as at present; but the State would be satisfied with less than half the revenue of the companies. In fact, it would be perfectly feasible to telegraph the whole of the letters now exchanged between the two countries for the sum which is now paid to the mail steamship companies."

ROTARY-CURRENT AND ALTERNATING-CURRENT DYNAMOS OF THE ALLGEMEINE ELECTRICITATS-GESELLSCHAFT.*

BY M. VON DOLIVO-DOBROWOLSKY.

The relatively large number of poles in alternating-current machines which were necessary to reach a high number of alternations at a small number of revolutions, rendered an economical design of the field magnets most difficult. A certain saving was, however, effected by using one field winding to do the whole work, instead of exciting each pole separately. The first alternator of this kind was probably that of Klimenko, of Charkow, which was exhibited

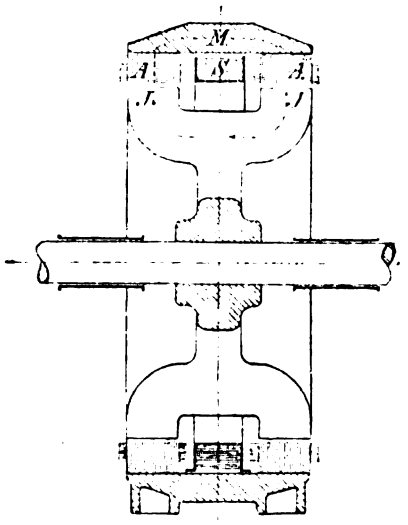

FIG. 1.

at the Vienna Exhibition of 1883. The bad proportioning in the design of this machine prevented it from coming into a more general use. The Mordey alternator of the latter end of the eighties, which is really derived from the Klimenko machine, was, in fact, the first practically useful machine with a single-coil magnet. To-day there are many modifications of this type of machine in existence, as, for instance, the one built by the Machinenfabrik Oerlikon with Brown's inductor and several others. One might predict that the single-coil magnet arrangement will come to the front in the construction of alternators in the same

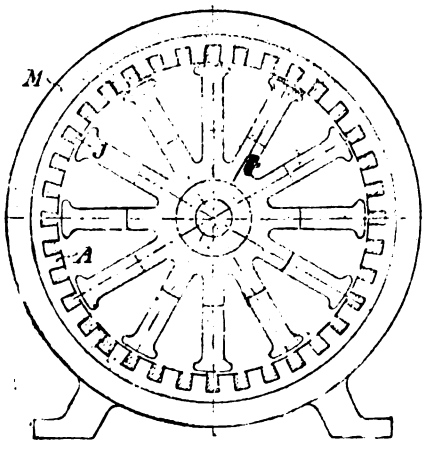

FIG. 2.

way as the ring-pole arrangement with radial magnets has, in the case of continuous-current dynamos, displaced all previous forms of magnets. Besides its main advantage, economical excitation, the exciting coil of a single-coil magnet in some of its forms may be made stationary, so that only the magnet core with its poles revolves. The 1883 machine of Klimenko was without any revolving wires. On the Mordey alternator the magnet coil could also be made stationary; the reason for not doing this in practice lies entirely in the mechanical difficulty of securing the relatively heavy coil to the light disc armature in a workmanlike way. After this introduction, I come to the description of two types of alternators built by the Allgemeine Elektricitäts-Gesellschaft, of Berlin.

Both types belong to the single-coil magnet class with stationary winding. The first kind, shown in Figs. 1 and 2, is most suitable for high speeds, consequently for belt or rope driving. From both illustrations it will be seen that the magnetic circuit is completed by the outer case, M, the two armature rings, A, which are built up of laminated iron, and the tooth-wheel or turbine-wheel inductor, J, which latter is shown separately in Fig. 3; S is the exciting coil and is fixed to the frame, M. The pole-pieces of the inductor wheel give rise on the inner face of the armature rings to points of very uneven distribution of field, so that by rotating the inductor the armature coils, which are to be seen in Fig. 2, receive an induction through the number of lines of force which flow in them being changed. On the outer face of the armature, A, the distribution of field is homogeneous, and therefore nothing prevents the lines of force being led through the frame, M. Here I will remark at once that similar machines have been built by Stanley in America, and by Sollman, of Wahl and Co., in Russia. A

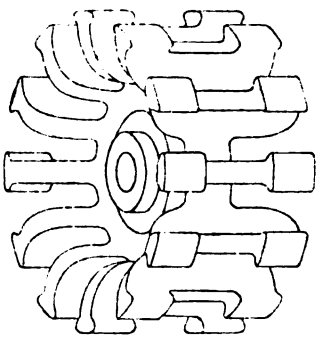

FIG. 3.

number of alternators of this type has been designed, some also with the modifications as shown in Fig. 4. A 100-h.p. "drehstrom" generator of this type is now at work at the sugar refinery of Messrs. Schwengers Söhne, at Uerdingen, on the Rhine. Of course this kind of machine is suitable for either single-phase, multiphase, or "drehstrom" current. In Fig. 2 the number of armature coils is three times as large as the number of pole-pieces, whereby three currents of 120deg. phase difference are produced. Instead of the pole-like arrangement of the armature winding, the opposite coils can be connected, which is admissible for machines of low voltages, and sometimes even an advantage. In larger size machines the bar winding can be used, as shown in Fig. 5, where each of the coils consists of only one copper bar. Three machines of this type, of 300 h.p. each, are at present under construction at the works.

Besides this type of machine, which is, as stated before, more to be recommended for the high speed, we are also building a slow-speed machine of a smaller width, but greater diameter, suitable for direct driving. The same is also on the Klimenko principle. Figs. 6 and 7 show clearly that the magnetic lines generated in the large exciter coil, S,

FIG. 4.

run evenly through the iron ring, M, and the two armature rings, A, when the magnetic circuit is closed by pole-pieces, P. When these pole-pieces, which are fixed to the flywheel of the engine, rotate, points of high magnetic density evidently travel along the surface of the two armatures, and the armature coils, which are clearly shown in Fig. 6, receive an induction. Things can, of course, be also arranged for multiphase currents by simply using a proper number of coils relatively to the poles. Rotary-current dynamos of this class are at present being built for the electric supply station at Strassburg—viz., three of 400 h.p. and two of 200 h.p. each.

Besides the advantage of having no collecting brushes, the

* Paper read before the Elektrotechnischer Vorein, Berlin.

Digitized by Google

little attention which these machines require, the simple and strong construction, is at once evident even from the illustrations. It is impossible to touch the high-pressure coils when the machine is running, as the revolving flywheel in front of it prevents this. When repairing the whole frame can be moved back, and the armature winding becomes easily accessible. As to the electrical advantages of this type of machine, two must be specially mentioned—first, the economic excitation; secondly, the very small drop of potential. Some consideration should also be given to the naturally small hysteresis, which, in combination with the little exciting

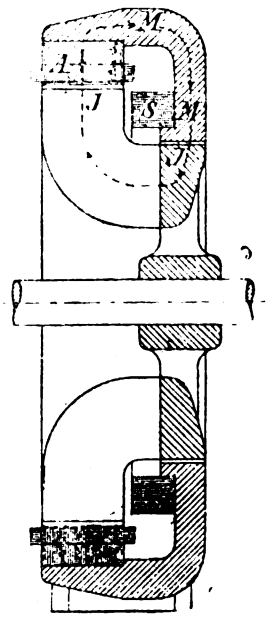

Fig. 5.

current required, enables an especially high efficiency to be obtained even at light loads. To demonstrate these advantages by data, I will give you the principal figures of the 400-h.p. machine for the Strassburg station: output, 280 kilowatts at 2,750 volts; revolutions, 150 per minute; number of poles, 40; weight of copper of magnet coil, 730 kilogrammes; weight of copper of both armatures, 200

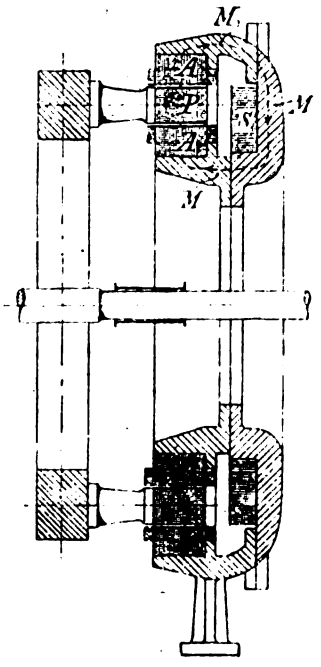

Fig. 6.

kilogrammes; excitation required, 4,000 watts—about 1·4 per cent.; total watts consumed in both armatures = 2 per cent.; total hysteresis loss about 1·3 per cent. This machine requires, in spite of the small loss, only a little over two kilogrammes of copper per horse-power. The ratio of the effective ampere-turns of one armature coil to the ampere-turns of the exciter coil is about 1·15.

That the weight of iron is not in consequence very high the following figures will show:

Frame	6,000 kg.
Both armatures	2,000 ,,
Pole-pieces	750 ,,
Total weight of iron exclusive of shaft and bearings...	8,750 ,,

Before I conclude, I would like to refer once more to the discussion of last meeting on the most suitable fall of potential in alternating-current dynamos. As is known, Hopkinson in the eighties found by calculations that for the synchronous running of two alternators a certain ratio between resistance and self-induction was most suitable, and that the self-induction had the most important *rôle*. From this many concluded that plenty of self-induction must be provided, as it is nearly impossible to calculate the Hopkinson ratio in advance. But often the machines got too much of it, and the consequence was they would get out of step. This was explained by saying there was still not enough induction, and we eventually tried to bring the machine to such a point that by means of self-induction it could not give more than 1½ times its normal output. Mordey at the end of the eighties maintained just the contrary—*i.e.*, that alternators should have little resistance and little self-induction. The smaller the fall of potential of the machine the easier large currents could be got out of it. However, the most practical and demonstrative proofs of Mordey could not at once shake the general belief in self-induction, and the dispute is still unsettled to-day. Of course, after the many experiments with alternators with a small fall of

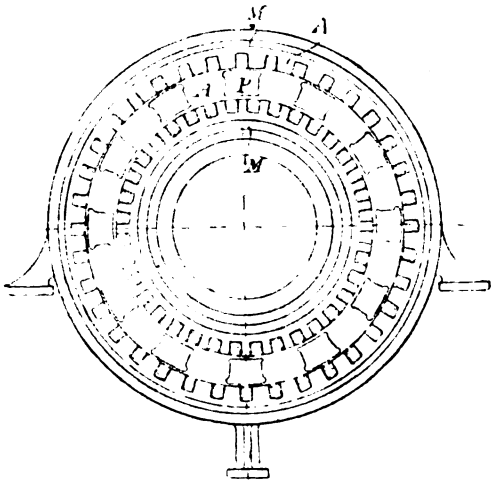

Fig. 7.

potential, which have been proved to run just as good in parallel as alternators with a large one, certain theorists have moderated their demand, and, in fact, are already satisfied with a fall of potential of from 15 to 20 per cent. I think one can predict that dynamo constructors will soon come to the general opinion that a little fall of potential more or less is of no consequence to good parallel running, especially as there are no practical proofs that too little resistance or self-induction has ever prevented alternators running in parallel satisfactorily. When, however, neither parallel running nor the conditions of synchronism require a large fall of potential, the most important argument for building alternators with self-induction disappears. The fall of potential has many disadvantages which are specially felt in motor driving. The wattless current component operates with its full ampere-turns in the direction of the magneto-motive force of the primary machine; therefore with motor currents one has a bigger reduction of the magnetic field than with lighting currents, and a machine of the latter class with a fall of potential of 15 per cent. is therefore not suitable for satisfactory motor work. If we consider that small motors seldom have cos ϕ more than 0·7 and large ones scarcely above 0·87, and, on the other hand, figure to ourselves that the wattless component amounts to from 0·7 to 0·5 of the whole current, we can easily perceive what a detrimental result the above-mentioned subtraction of ampere-turns must have. As, however, at the present time the motor question requires the greatest

Digitized by Google

consideration on the part of electric supply stations, doubtless the question of dynamo design will be answered in one way only—that is, to have the smallest possible fall of potential. No lowest limit can be fixed to this, as even the best of existing machines are far from being perfect in this direction. In my opinion, and according to my experience, it is entirely necessary and quite possible that the fall of potential due to the lighting current should not exceed 4 to 5 per cent., as even then we have still at full load with motor current a fall of from 15 to 20 per cent. The only intelligible reason which was brought forward against such machines is the danger of short-circuiting. Experience with continuous currents has taught us, however, that the dynamos are better protected by good fuses and automatic cut-outs than by a counter-compound winding. Therefore with alternating-current—rotary current work—we can very well do without the self-induction, which otherwise only deteriorates the machine.

In conclusion, I should like to remark that in the last part of my paper I have treated the self-induction and armature reaction to a certain extent as one, which is not quite correct. However, it was rather an explanation of the self-induction itself I wished to give you to-day than its origin and calculation. Besides, both phenomena are very nearly related and generally appear together, and are of the same order, so that machines with much reaction have likewise large self-induction, and *vice versâ*.

THE BLONDEL LUMEN-METER.

This is an apparatus for the direct determination of the mean spherical intensity of a source of light. M. A. Blondel has designed this new method of measuring more quickly and accurately than by any previous attempt mean spherical candle-powers with a view to overcoming the old laborious methods, which were complicated and uncertain. He encloses the source of light to be measured in the centre of a sphere, Fig. 1, carefully blackened inside,

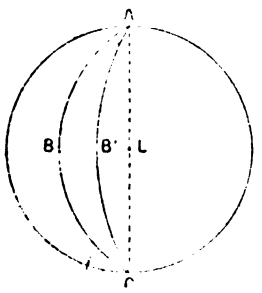

Fig. 1.

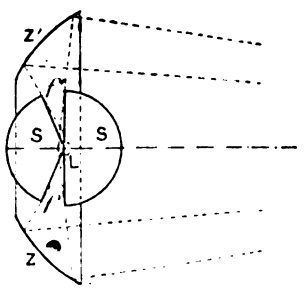

Fig. 3.

and having one or more openings of the segment shape shown in the figure. The rays of light which come out from one of the openings, A B C B', of a solid angle, α, is a determinate part of the total light emitted. If the source of light is symmetrical all round the axis A C, it is sufficient to measure the light emitted by the aperture, and to multiply it by $\frac{\alpha}{2\pi}$ to get the value of the total flux, Φ, then the mean spherical intensity, I_m, can be obtained, as

$$I_m = \frac{\Phi}{4\pi}.$$

If the light is not symmetrical, and the angle α is $\frac{1}{n}$ of 2π, then it is necessary to measure the light when the aperture is in n different positions round the light. If, instead of the spherical candle-power, the light passing to the lower hemisphere only is wanted, the aperture must be shaded on the upper side of the horizontal plane passing through the light.

Such is the general principle of the new method which has recently been devised and put in working order by M. Blondel. In order to measure the light passing through the segmental opening, its effect is concentrated by a projector, M, on to a diffuser screen, G (Fig. 2), which will disperse the light by transmission or reflection. Care must be taken that the system of reflectors shall cause all the rays of light to fall on the screen almost normally (the admissible error in direction may rise to 40 per cent. for certain diffusers, such as opal glass, but must not exceed a few per cent. if a paper screen is used). The photometer, P, is placed opposite the screen in such a way that it receives the diffused rays only, and at such a distance from it that the angles made with the rays of light on the photometer surface are sensibly the same for all parts of the luminous screen. The other face of the photometer is lighted by the standard light, I^1. As the positions of the projector, the screen, and the photometer are fixed, the standard lamps have to be moved to get a determination. It can be easily shown that the lighting effect produced in the photometer, P, by the illuminated screen, g, is proportionate to the light emitted from the aperture; or, in other words,

$$E = A\,\Phi,$$

A being a constant depending on the joint effects of the coefficient of reflection of the projector, the coefficient of diffusion of the screen and the distance, l, between that screen and the photometer. In displacing the standard, I^1, to a distance l^1 will give an equal light on the two faces of the photometer, one gets that—

$$\frac{I^1}{l^2} = A\,\Phi.$$

From which Φ is obtained when the constant A has been determined from preliminary experiments with the apparatus.

For the projector, M. Blondel uses preferably an elliptical or parabolic mirror. By limiting the active part to a vertical plane through the focus, as is shown in Fig. 2, the light emitted to a hemisphere can be collected. Two measurements then suffice to measure the total flux. But the angle of incidence of the rays on the glass then varies within wide limits, and it follows that there are from 5 to 6 per cent. variations in the reflecting power at different points of the projector. The constant A is therefore bound to be inaccurate. So M. Blondel, after having tried many ways of solving this difficulty, prefers for accurate work to limit the apertures to two small symmetrical

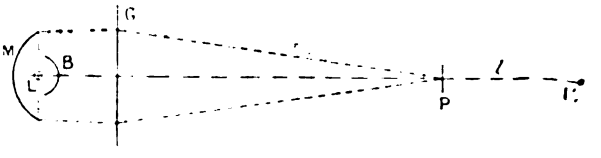

Fig. 2.

segments of about 18deg., Fig. 3, thus keeping down the variation in the angle of incidence. In this case the variation of reflecting power does not reach 1 per cent., and the mirror can be reduced to an elliptical zone of revolution made to reduce to a minimum the dimensions of the lighting portion of the screen. This screen is placed about 10ft. from the mirror, and the space between it and the photometer is about the same. The zonal lumenmeter, which has been manufactured by Messrs. Sautter, Harlé, and Co. at their own expense, is represented diagrammatically by Fig. 3 and in perspective by Fig. 4. An opening is left at the top for the arc lamp to be admitted into the sphere, which is made in one with the reflector. For gas and other lamps the apparatus can be inverted by turning it round the pivots (seen in Fig. 4), so that the opening comes at the bottom. To assist in the introduction of the lamps a portion of one hemi sphere can be removed, as it is only held in position by two buttons. It will be noticed that the apparatus is so arranged that no stray rays can escape.

With a view to facilitate the employment of his method in laboratories, M. Blondel has designed a more simple but less accurate apparatus manufactured by the same firm. In this design the zone of silvered mirror is replaced by a conical zone of a white diffusing material much less costly. The diffusing screen is then dispensed with, and the photometer is placed on the axis of the cone at as great a distance from it as possible compared with its dimensions. The emitting power of the cone being proportional to the light,

Digitized by Google

if the diffuser is well chosen (M. Blondel advises a matt enamelled surface, easily obtained), it can be proved that the light thrown on the photometer, fixed sufficiently far away, is proportional to the flux of light to be measured. It is a good plan, in order to avoid the errors resulting from reflection from the diffuser on itself, to use in this case only one segment instead of two. This new apparatus described above, called by its inventor a "lumen-meter," seems likely to be of great use in photometry. It gives a ready means of ascertaining the light-giving properties of various sources of light.

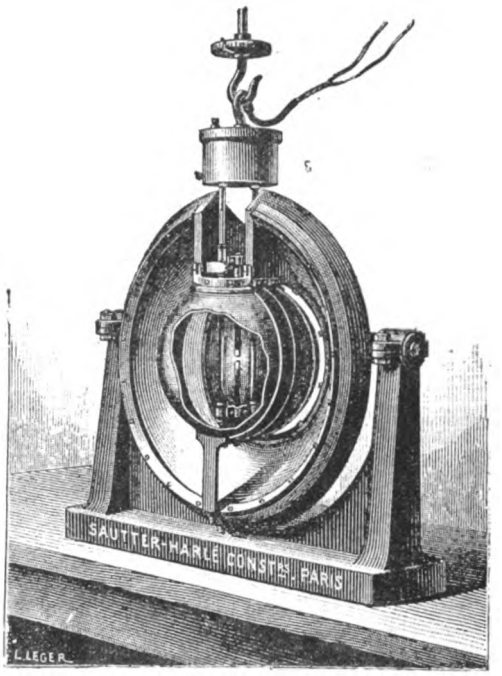

FIG. 4.

We cannot better illustrate the practical use of the apparatus than by citing an experiment made with it by M. J. Rey. The reflecting zone type was used, and he presented the results obtained to the Société des Electriciens during the last session. M. Rey has compared the light emitted by an arc using the same power with two different sets of carbons, with the object of showing the influence of the diameter of carbons on the lighting efficiency. He found the following values:

Current in amperes.	Volts.	Diameter of carbons, in millimetres.			
		+ 21	− 13	+ 14	− 9
		Φ in lumens.		Φ in lumens.	
20	44	7.900		21,330	
25	44	9,430		33,830	
30	45	16,260		46,330	
35	46	28,100		61,330	

The lumen is the unit adopted by M. Blondel in this system of measurements. It is equal to the light emitted from a source having an intensity of one decimal bougie in a solid angle equal to units. The figures of the table divided by 4π give the mean intensities in decimal bougies. The results show that the light emitted is threefold, due to the change in the carbons. One cannot therefore attach too much importance to the judicious selection of the size of carbons, and to the practical means which permit such comparisons to be easily ascertained.

ELECTRIC LIGHTING OF TRAINS.—V.

BY R. W. WEEKES, WHIT.SCH., A.M I.C.E.

(Concluded from page 652.)

I have now described the apparatus used for train-lighting on the three railways on which it has been extensively employed. On other lines isolated trains have been lighted electrically; and on others, again, attempt are now being made to introduce new systems. On the London and Tilbury Railway, electric lighting gear which is stated to fulfil every reasonable requirement is being tried. The inventors of this apparatus do not consider that their apparatus is yet sufficiently perfected to be described. They have followed on the lines laid down by Mr. Langdon as being required for an ideal system, and have lighted every carriage independently. Each coach thus contains its own dynamo and accumulators. The train can be uncoupled at any part, or any single carriage can be attached to a train which is lighted by either oil or gas. It will be interesting to learn if this apparatus is sufficiently simple to keep both the first cost and cost of upkeep within reasonable limits.

There is yet one system of electric lighting, largely used on the District and Metropolitan Railways, to be described, although the light supplied by it has to be paid for by the public. This is the automatic penny-in-the-slot lamp installed by the Railway Automatic Electric Light Syndicate. These lamps, which are illustrated by the following figures, have been devised by Messrs. Davies and Tourtel to supply the public with a convenient reading lamp. The lamps are placed in the four corners of the compartment in such a position that the light is projected over the shoulder of the traveller and concentrated on to his book or newspaper. Each compartment has its own accumulators for supplying the light, but it has been found advantageous to connect all the carriages in parallel. When this is done, an accident to one set of accumulators, such as the breaking of a lug, does not cause failure of light. The functions of the lamp are as follows: on the passenger placing his coin in the slot he releases the switch, and on this being pressed home he receives light for half an hour which enables him to read with comfort. The next feature is the honesty of the apparatus; should the lamp be faulty, or the battery connection broken, the coin is returned forthwith.

The batteries are taken to be charged to the company's headquarters at Mill Hill Park, Acton. The outfit of this charging station was described in the *Electrical Engineer*, vol. xiii., page 137. Six special trucks were designed by the engineer for conveying these batteries. The general arrangement will be understood from Figs. 29 and 30. Fig. 29 shows the elevation partly in section. Each truck is capable of taking four rows of seven boxes of accumulators, each box containing six cells. The boxes in each row are connected up in series, so that a charging voltage of about 105 volts can be used. The charging shed or siding will take three trucks at a time. Mr. Tourtel, who has complete supervision of the whole plant, makes it a rule that every box of accumulators shall be recharged at least once a week, even in summer, when the demand for light is not so great. In this way the accumulators receive regular attention, and their life is correspondingly increased. I am unable to obtain figures as to the actual cost of maintenance, but the present staff, both on the line and at the charging station, would be able to handle successfully a much larger number of trains so lighted. The company have fixed their lamps in carriages which are also well lighted by gas, but I should expect these automatic lamps to have a much larger support on those local lines round London which still use oil lamps in their suburban trains.

The mechanism by which the lamp is automatically worked when the coil is inserted is shown in Figs. 31, 32, and 33. On being inserted, the coin falls into the pocket, C. This pocket also acts as the arm of the switch, but the plunger, A, does not engage with it unless there is a coin in the pocket. When A is pushed back, an armature, E, is brought up to the magnets, H H, which holds it back when the current passes. Should the apparatus not be in working order, the armature and coin pocket move back as the plunger is released, and the coin is returned down the shoot, R. Otherwise, if the current passes the coin falls to the bottom of the box.

The act of pushing back the plunger, A, also winds up the clockwork by means of the circular rack, J, and closes the circuit through the switch, J_1. A projection, *a*, on the plunger engages with the lever, N, and starts the balance-wheel of the clock. The clockwork is designed to run for half an hour, during which time the rack, J, is

Digitized by Google

slowly resuming its original position. Finally, the rack breaks contact with the spring, J_1; the magnet thus loses its power, and the spring, V, brings the coin pocket back into the position shown in the diagram, Fig. 31.

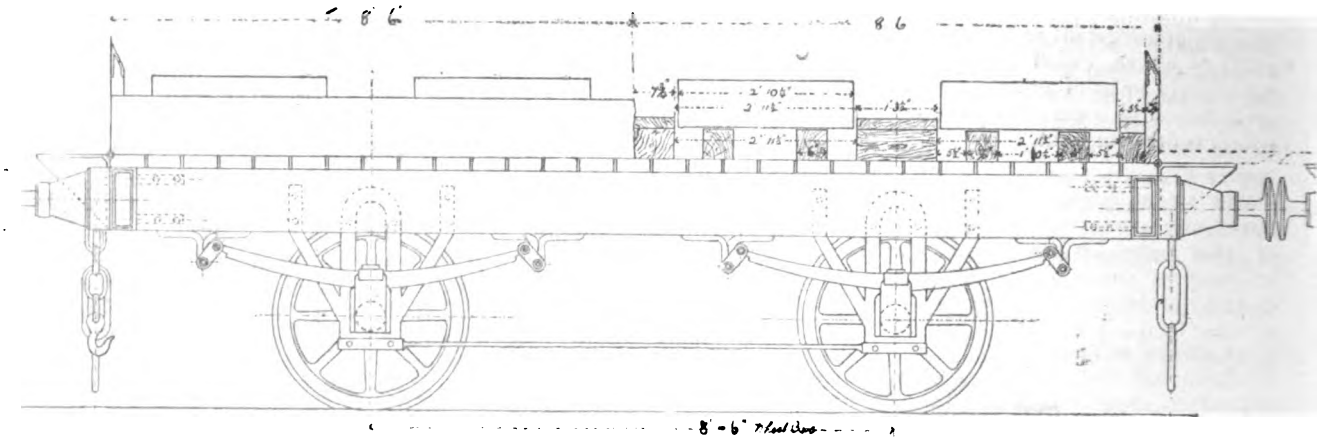

FIG 29

Should the passenger be leaving the train before the expiration of the half-hour, he can extinguish the light by pressing the small plunger, P. This plunger engages with the slide, P_1, and breaks contact by removing the spring, G, from its normal position. The small incandescent lamp is placed in a socket-holder insulated from the case. The reflector, *y*, is attached by two screws, *b*, b_1, worked in circular slots, *c*, c_1, to the main casting. The parabolic lens, Z, can thus be turned round the axis of the lamp, so as to project the light at the required angle. In this way the light is available to eight persons in the carriage—*i.e.*, those occupying the corner seats and those adjacent to them. A special board is fixed to the carriage as a support for the lamp, and it contains three contact springs—two being for the lamp supply, and the remaining one on an alarm circuit. This is arranged to ring a bell in the guard's van should the lamp be forced open by the enquiring public. There is, however, no excuse for this rough treatment on the ground that the apparatus receives the penny when out of order, as is the case in some automatic machines.

The Cost of Electric Train-Lighting.—Very few figures are available as to the actual cost of electrically lighting trains in England. On the London and Brighton and South Coast Railway, where some 40 trains are so lighted, the annual cost per train is stated by Mr. E. J. Houghton to be £54. In this item no charge is made for extra cost of

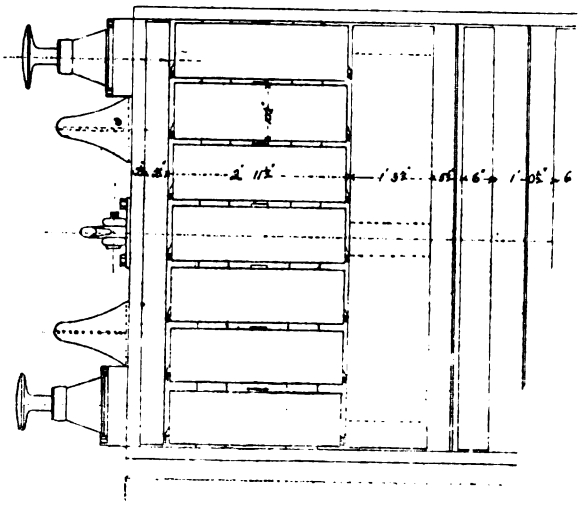

FIG. 30.

coal on the locomotive due to the power absorbed by the dynamo. As no allowance for this is made to the engine driver in his coal supply, I conclude that the quantity is small. On the Great Northern Railway, where a somewhat similar arrangement is used, the annual cost per train is given as £150. The apparent great difference between these two figures can be explained to some extent by the fact that the Great Northern have fewer trains lighted electrically, and that the candle-power per train is greater. The whole point hinges chiefly on the question of cost of supervision, and it will be readily understood that this cost decreases rapidly as the number of trains lighted increases. Even assuming that the £150 per annum is the present cost on the Great Northern Railway trains, it follows from the figures furnished me by Mr. Ireland that the average cost per unit throughout the year is only 7¼d.

It is also difficult when the head official in charge of the electric lighting of the train has many other important

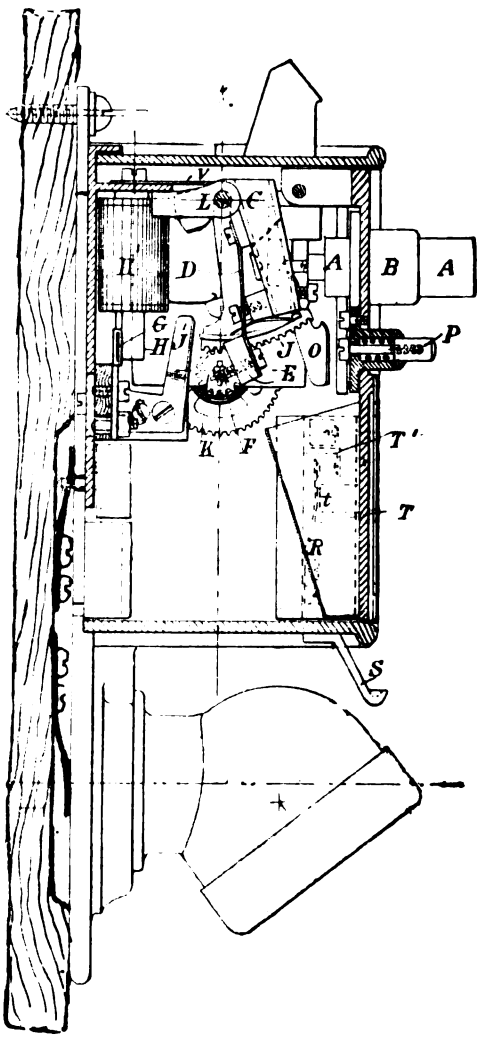

FIG. 31

duties to perform to correctly divide his remuneration over the various departments. This may also account for the discrepancy between the two figures given above. I am assured by three engineers in charge of three of the largest lighting schemes that the average life of the accumulator used for railway work ranges from 2½ to 3½ years. It will be thus seen that the upkeep of accumu-

Digitized by Google

lators forms one of the largest items in the annual cost of the various train-lighting systems used in England.

Besides the cost of renewing, say, one-third of the batteries each year, there is the cost of examination and nursing of sick batteries.

The question naturally arising is, Are we obliged to use accumulators so largely for train-lighting? Their use is necessitated from the present universal method of driving the dynamo from the axle of the carriage. The variation of speed, and at times the cessation of generating power, forces the engineer to use storage batteries. It also requires that a larger dynamo shall be employed, as the whole of the power required for lighting has to be generated and partly stored during the time that the speed of the train exceeds certain limits. Again, a large amount of automatic machinery is required with this method of driving to ensure even fairly constant pressure at the lamps. While recognising the advantage of this method of driving in some respects, its absurdity in others

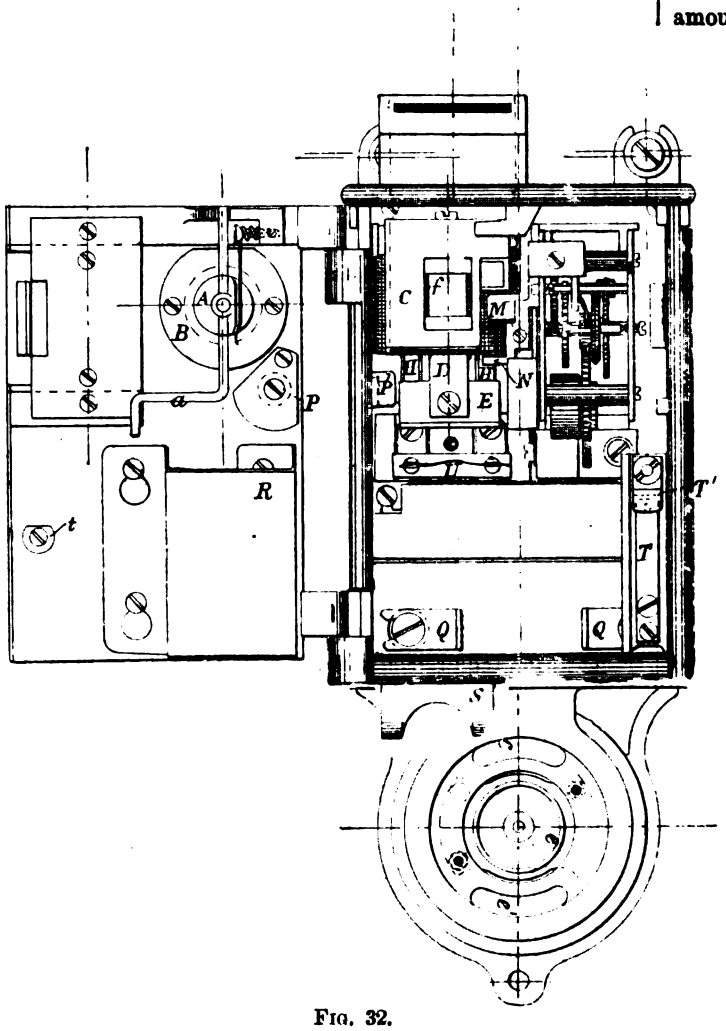

FIG. 32.

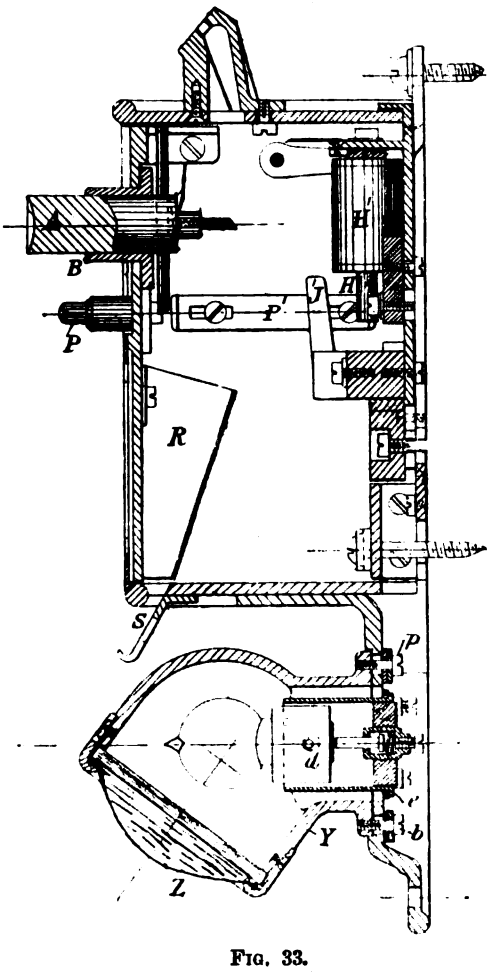

FIG. 33.

can be seen from a parallel arrangement for electric lighting of steamships. No engineer has, I believe, yet proposed to drive the electric lighting machinery on a steamer by means of a paddle-wheel caused to revolve by the passage of a ship through the water.

Instead of this, the available boiler pressure is used to drive special electric lighting engines at constant speed, and I believe that the same system would be found both cheapest and best for railway lighting. The first cost of plant would be considerably reduced. The automatic gears now so largely used would be dispensed with, and batteries of small capacity would only be required on the long express routes to supply the light while the engines are being changed. This system of lighting was tried on the Great Eastern many years ago, but given up on account of the uneconomical engine employed for driving the dynamo. The dynamo and engine for driving it should be placed on the engine, unless at first it is better to have it in the guard's van, and steam supplied to the engine by a flexible steam-pipe. The engine driver in either case could give the plant sufficient attention if efficient oiling arrangements are adopted and good governing gear.

Some figures as to the cost of electric lighting of trains in America were given by Mr. W. B. Leonard in a paper read last year before the American Society of Railway Telegraphists. These figures, owing to the short time most of the systems have been at work, are not to be depended on to any great exactness, but are interesting. The first cost of various systems of lighting trains by electricity, and also of the annual expenses of working, the light is appended. The figures are given for the five following different electric systems, and compared with those for oil and gas.

(*a*) Lighting direct from a dynamo, as arranged by Mr. G. Gibb, engineer to the Chicago, Milwaukee, and St. Paul Railway. In this case a 15-kilowatt dynamo is coupled to an 18-h.p. Westinghouse engine placed in the luggage van and supplied with steam from the locomotive boiler. In winter the boiler which is used to heat the train supplies this engine as well. The number of 16-c.p. lamps per train amounts to 225 in some cases.

(*b*) Lighting by dynamos with accumulators in each carriage, as used by the Pullman Company.

(*c*) Lighting by accumulators only, as used by the Pullman Company.

(*d*) Lighting by accumulators only, as on the Chesapeake and Ohio Railway.

(*e*) Lighting certain carriages by dynamos driven from the axles and using accumulators in the intermediate carriages, on the Lewis system.

(*f*) Lighting with Pintsch gas, with burners 6 c.p.

(*g*) Lighting by oil with a duplex burner giving about 2 c.p.

In all the electric systems 16-c.p. lamps were used. Mr. W. B. Leonard has assumed that the light is used each day for 10 hours, and has based his figures for the daily cost on this uniform assumption. He points out that the Gibb system is not applicable to trains which have to be subdivided in route, but is convenient for the main-line express trains. He also states that the Lewis system had only been in regular work for three months when he

Digitized by Google

obtained the figures, and that they may therefore be too favourable.

COST OF TRAIN-LIGHTING IN AMERICA.

System of lighting.	Cost of fitting per carriage.	Total c.p. of lamps per carriage.	Cost of lighting	
			Per carriage per day.	Per c.p.-hour in pence.
Electric.	£ s. d.		s. d.	
(*a*) Direct from dynamo—G. Gibb	67 12 0	288	3 11	·0162
(*b*) Dynamo and accumulators—Pullman Company	193 12 0	360	7 11½	·0264
(*c*) Accumulators only—Pullman Company	130 0 0	482	6 9½	·0210
(*d*) Accumulators only—Chesapeake and Ohio Railway	141 16 0	148	3 9¼	·0246
(*e*) Dynamo and accumulators—Lewis system .. Gas.	100 0 0	192	1 11	·0117
(*f*) Pintsch gas	80 0 0	148	3 9¼	·0306
(*g*) Oil	14 8 0	148	2 6½	·0206

In conclusion, I have to thank the engineers of the various railway companies for the generous way in which they placed the information gained by years of careful work at my disposal. Also I am indebted to them for many of the drawings which have accompanied my descriptions.

TRAMWAYS INSTITUTE OF GREAT BRITAIN AND IRELAND.

The annual general meeting of this institution was held at the Holborn Restaurant yesterday (Thursday). In the absence of the president, Mr. Carruthers Wain, the chair was occupied by Mr. Mason.

Mr. JOSEPH M. SMITH moved the re-election of Mr. Carruthers Wain as president, which motion was carried. Mr. William Neale, of the Birmingham tramways, was added to the list of vice-presidents. The auditors were re-elected. It was agreed that the next meeting of the institution should be held in the Isle of Man in September next. Mr. MASON suggested that the winter was a bad time for holding a meeting, and that the "quarterly meeting" in the winter months should be held "half-yearly." This was approved of. It was decided that the spring meeting should be held in Birmingham.

Mr. ALFRED DICKENSON opened a discussion on "Traction up to Date," with special reference to the report to the Newcastle Town Council by Mr. W. G. Laws, their city engineer. Mr. Laws had recommended the use of cable tramways as being specially applicable to his district. The figures and facts given by Mr. Laws had been dealt with in very cavalier fashion. A cable line could not be constructed at anything like the price stated by Mr. Laws. The cost of the Brixton cable could not be ascertained, the secretary having instructions not to give any information; £200,000 would, however. be about the cost of that line. The construction of the road bed alone would be £10,000 a mile, and it was absurd for Mr. Laws to suggest that a cable line could be carried out with equipments for £10,000 a mile.

At this point Mr. CARRUTHERS WAIN appeared and took the chair, and apologised for being late, he having been thrown out of a cab in coming away from the meeting the previous evening held at the Foreign Office in connection with the Railway Congress. He had been charged with the mission from the institute to show how much extension was possible if the Board of Trade could be shown the advantage of giving the tramway companies fair-play. There was little to be thankful for in connection with light railways, but he was informed that the Board of Trade were open to approve of a Bill ameliorating the condition of tramway traction. It had been suggested that the question of reserve funds should rather be considered by the institute than new inventions, but he considered that the council would not be doing their duty if they did not afford every facility for trying new inventions. The institution had to be kept in constant touch with Westminster, as when they successfully opposed the transference of powers from the Board of Trade to local authorities. The institute had opposed the London County Council's Tramways Bill and the Eight Hours' Bill, the London County Council's Valuation Bill, and the question of betterment. The institute could be made far more effective if the other companies not associated with them would join them. The tramways were not at present a united industry, though they should be. He had two years ago advocated electric welding of tramway rails, which had been scoffed at then, but it had been successfully dealt with in America. While at one time electric traction by overhead wires would have been condemned here, the Stafford tramways showed that there was now a more reasonable condition of affairs. He found that where an improved service was to be given, there was a disposition on the part of the municipalities with whom he had to deal to grant extended leases. He questioned whether a municipality could work a tramway line as economically as a company. The Glasgow Corporation, for example, were not actually making a profit. His opinion was that they were being worked at a dead loss, and this would be shown when undeceptive accounts were produced.

The report of the institute was then read, in which it was pointed out that they had opposed legislative encroachment on tramway enterprise. Unity among tramway companies was urgently required. Mr. Wain had represented the institute on the light railways enquiry. There was great scope for development of tramways by private enterprise. The report was adopted.

Mr. ROBINSON suggested that a movement might be made to get shareholders of tramway companies to join the institute.

Mr. ROTHWELL resumed the discussion on Mr. Laws's report. He was sure that the report was quite absurd.

Mr. ELLIOTT said that Mr. Laws considered that he could not take part in the discussion on the matter owing to his position.

Mr. WAIN said that the ideal horse was the best motive power in certain districts, steam in others, cable elsewhere, overhead electric traction where towns had to be united. All forms of traction had their limits, and also special facilities. What was wanted was the best means of adapting traffic to the requirements of the district dealt with.

Mr. TURTON, of Leeds, said they had been greatly hampered by the Municipality in working their lines. Now that the Corporation had got the lines, they should be able to make a profit of 15 per cent. They had, of course, the advantage of getting their capital at 3 per cent. Steam had been the life of many lines.

Mr. MASON said that the total profit made at Leeds was £56 for 14 months.

Mr. SCOTT RUSSELL said that Mr. Laws appeared to have started with the intention of advocating cable against other systems, and had done so—an easy matter enough, for it was simple to pick holes in other systems. Mr. Siemens had demolished the objections to the underground electric conduit system. At Northfleet no difficulty had been experienced in connection with the ⅝in. slots on the electric tramway there. The conduit system should have a good future.

Mr. CONRADI had for years studied the question of the best mode of traction, and it was best to use steam in preference to any other mechanical motor. Electricity had made great strides in America, but he did not think that overhead wires were suitable here. Improvements might, however, be made in connection with accumulators and lead to developments.

Mr. SELLON said that Mr. Laws had been misled by not having gone to the proper sources for his information. The voice of Mr. Colam appeared throughout Mr. Laws's report. Cable traction was not suitable for narrow streets like those of Newcastle. The report could not commend itself to tramway men.

Mr. W. NEALE, of Birmingham, did not think that there was nothing like the steam-engine, as some speakers had said. He preferred cables to steam, complaints being made as to steam-cars. They had a good accumulator

Digitized by Google

system, but it had proved a loss, the line (the Bristol-road) being a suburban one with but little traffic. It would not pay to lay down a cable there, but he agreed that accumulator traction might have a good future. Their horse-traction lines did not pay at all.

Mr. GEORGE CAWLEY, M.I.M.E., then read his paper on the "Thwaite and Cawley's System of Electric Haulage," which we print elsewhere.

Mr. COOPER stated, in connection with the paper, that the use of refuse destructors in connection with the generation of steam for the stations for such a line proved economical. About 3½lb. of refuse was equivalent to 1lb. of coal.

Mr. A. G. NEW next read the following paper on

The I.E.S. Storage Battery for Lighting and Traction.

The storage of energy of all kinds is one of the most important problems of the day, and particularly the storage of electricity. The chief objects to be borne in mind in the design of storage apparatus of all descriptions are: firstly, efficiency; secondly, compactness and lightness.

As regards the first of these, when dealing with electrical accumulators, a very fairly high efficiency—when the batteries are new—is obtainable, but the chief difficulty in the past has been to obtain a large capacity with a small amount of weight and size, and to obtain a battery in which the plates do not rapidly deteriorate under electrical or mechanical strains. Up to the present time lead is the only material which can be used efficiently for the construction of plates for this purpose, and its high specific gravity naturally involves great weight.

It may not be out of place to briefly summarise the existing forms of accumulator plates which have been made in the past, as it will then be easier to point out the advantages which are possessed by those known as the I.E.S. The plate which has probably commanded the highest sales has been the E.P.S. plate, and this consists of a grid formed of pure lead constructed in such a way as to have cavities on its surface for holding the active material, oxide of lead. The Epstein and other forms of Planté plates have the active material electrolytically formed in place from metallic lead, but these being very solid are very heavy. Other forms of plates have been made in which fibrous substances are mixed with the active material in order to bind it and prevent its falling away. Practice shows that when an accumulator plate is subjected to charging the active material expands, and that this expansion is no mere theoretical amount, but sufficiently noticeable to render the adhesion of the oxide to any other portion of the plate which does not expand a difficulty. In the type of plate known as the E.P.S., the expansion of the oxide of lead plugs tends to stretch their leaden seatings, and consequently when they again contract they only fit loosely in their places—the harm thus brought about being twofold: firstly, bad contact; and, secondly, a tendency for sulphating to take place.

Another important point in the construction of accumulator plates is to obtain as large an active surface as possible and, by avoiding any actual contact between the lead conductor and the acid, to prevent any rotting away of the lead. The disadvantages arising from the neglect of these two most important points is noticeable to anyone using the E.P.S. accumulator. Experiments which have been carried out within recent years by the inventors and proprietors of the patents now being worked under the name of the I.E.S. accumulator, have shown that the most essential points in the construction of plates are the following:

1. The conductor should be as light as possible consistent with being made of pure lead, and being within a short distance of every particle of the active material. It should, moreover, be entirely covered by the active material, and under no conditions should it come into contact with the electrolyte. It should be, at all points, covered to such a depth with the oxide that no electrolytic action takes place upon itself.

2. The active material should offer as large a surface to the electrolyte as possible, and should be so held as to be able to contract and expand without loosening itself from the conductor or allowing particles of its surface to fall away. The shape of the plate should be such as to require the smallest quantity of active material consistent with an equal and sufficient depth of active material over every part of the conductor. On no account should it be possible for the oxide to shift or for its particles to travel when being used.

3. The general formation of the plate should be such that any mechanical contrivance for holding the active material in place is capable not only of allowing it to expand but also of contracting with it when it contracts—that is to say, the holding-in material should be sufficiently elastic to keep the complete plate in rigid and secure condition at all times.

The I.E.S. plate fulfils as far as is possible at the present time, and with the present amount of practical experience, all these conditions, being constructed in the following manner: The conductor is made of lead shaped into a grid somewhat like a comb, and this grid is then fitted with strips of perforated sheet celluloid in the manner which has proved most successful from a practical point of view. The active material is then laid on, and the whole plate at this stage of its manufacture presents a surface entirely composed of the lead oxide. It is then slipped into a perforated celluloid envelope which it fits closely. The plate is then ready for use, and after its first formation by charging settles down into a solid and compact plate, which, however, can freely expand and contract to the required extent, and in which no travelling or movement of the particles of the active material can take place. The capacity of the I.E.S. plate is shown by experiment to be from three to five times that of an E.P.S. plate of the same size and surface. It is, moreover, capable of standing heavy charges and discharges to an extent which would soon destroy an E.P.S. plate. It will be seen that for traction purposes the I.E.S. plate is eminently suitable, and it is, in fact, at the present time the only accumulator in the market which is adapted for that purpose.

The cause of the enormous rate of depreciation in most accumulators previously tried for traction purposes is the jolting and constant vibration when in use and when at the same time expanding or contracting, which forces the particles of the active material to dislodge themselves and—in the case of the E.P.S. plate—causes the plugs to jerk out, thus forming a deposit at the bottom of the cell; this deposit not only has an injurious effect electrically, but also represents loss of active surface, and consequently impaired capacity in the cell. Experiment shows definitely and clearly that no deposit forms when using the I.E.S. plates, even on the roughest roads or when subjected to considerable vibration and jolting.

The cost of lighting trams by means of the I.E.S. batteries is doubtless a point of special interest, and I will, therefore, briefly show the exact cost per annum of lighting the cars which recently have been fitted up on the North Staffordshire Company's line. In the first place, I may mention that the complete battery for each car weighs about 54lb., is 13½ by 7½ by 7½ over all, and has a capacity of 40 ampere-hours at 16 volts. The total charging current necessary per battery per charge is 800 watt-hours, which is 1·072 electrical horse-power hours. Taking the actual cost of generation of current at 2d. per electrical horse-power, this represents a cost of 2·144d. The battery, when fully charged, is capable of lighting one 5-c.p., two 3½-c.p., and two 2½-c.p. lamps for 11½ hours, giving during that time a total light of 17 c.p.—the cost per car per hour being ·1861d. Taking 2,000 working hours per year, the annual cost of current per car is £1. 11s. The existing arrangement between the tramway company and the I.E.S. Company is one by which 2s. 6d. per week per car is paid as hire. This adds £6. 10s. per car per annum to the above cost; allowing and adding interest on capital expenditure for plant and fittings at 5 per cent., the annual cost per car is £8. 14s. 9d. If the tramway company were to purchase the batteries, instead of hiring them, the total cost to themselves per car per annum, after allowing 10 per cent. for depreciation and 5 per cent. interest on the extra outlay, would be £3. 11s. 9d., as against the previous £8. 14s. 9d. The total cost per five-light car per week is, therefore, as follows: (1 3s. 4¼d. hiring; (2) 1s. 4½d. purchasing—and these figures are obtained without the necessity of disfiguring the electric fittings and reflectors with advertisements.

For traction purposes the I.E.S. accumulator enables stored electricity to be carried with an extremely low weight as compared with any other accumulator in the market. A positive plate having 30 square inches of active surface (each side) has a capacity of 30 ampere-hours at a discharge of five amperes, weighing 30oz. This result brought down to units represents one square inch of plate, one ampere-hour, two watt-hours, 1oz. Allowing an 80 per cent. efficiency for the electric motor, it would be necessary to have a storage capacity of 900 watt-hours in order to develop one horse-power hour. This, calculated on the basis given above, which has recently been considerably exceeded, represents an active surface of positive plate 450 square inches, and would weigh 28lb. Adding the weight of the negative plates (necessary for positives having this surface), the total weight of the battery necessary for one electrical horse-power hour is 61lb. (a discharge during six hours being allowed for).

Taking, now, trams similar to those on the Birmingham Central, and allowing for a six hours' capacity at an average of 7 h.p. during that time, thus equalling 42 horse-power hours, the total weight in plates for this would be 22cwt., or, adding weight of boxes and acid, gives a total of 27cwt. Assuming an average speed of five miles an hour during the whole of the six hours, it would equal a 30-mile run, and the total capacity being 42 horse-power hours, we find that 1·4 horse-power hours is necessary per car mile. Allowing a total efficiency of 56 per cent.—that is, 30 per cent. loss for storage, and a further 20 per cent. motor loss—and taking the actual cost per electrical horse-power generated at the charging station, including all labour, depreciation, etc., at 2d., the actual cost of current per car mile equals 4·032d.

NOTICE.

We have received an unfinished letter from a correspondent in Storer-road, Loughborough. We are unable to reply to this letter because neither name nor number of house is attached.

LIGHT—MORE LIGHT.

Once again we may venture to point to the absurdity of public declamation against the amount of the bill for more light as compared with the amount of the bill for light. There is a strong tendency in civilisation to fight against Nature's laws. The hours of work may be shortened so far as the manual labourer is concerned, but to compete in business and ensure a return for capital sunk in machinery and other directions, relays of manual labour are called into operation. Nature says, Work while it is day; civilisation says, Work all day, and during as much of the night as possible. Business—and if we add to business recreation, still more so—means movement, and for its purposes plenty of light and means for locomotion are required. The growth of artificial light has been contemporaneous with what we term the growth of civilisation, and no doubt a century or two hence writers will ridicule the tendency of the nineteenth-century *fin-de-siecle* politician or biassed agitator to decry the necessary cost for more light. What is the history of the artificial lighting of public streets? Beckman, in his "History of Inventions," devotes a chapter to this subject, and points out that the lighting of streets, of whatever benefit it may be, is generally considered a modern invention. The Greeks and Romans—perhaps more sensible than their successors—preferred to follow Nature's dictates and worked while it was day, for there is no record to prove that the streets of Athens and Rome were lighted. The Romans, indeed, used flambeaux and lanterns for their nocturnal visits—nor, indeed, have we moderns entirely discarded their use. It is generally agreed, however, that during high days and holidays the streets, both under the Grecian and Roman *régime*, were illuminated. According to Beckman, the houses of the ancients were illuminated on birthdays by suspending lamps from chains, and in continuation of his narrative he states that, so far as he was able to learn, Paris set the example to the moderns of lighting its streets. This city, he says, in the beginning of the sixteenth century was much infested with street robbers and incendiaries, and the inhabitants were from time to time ordered to keep lights burning after nine in the evening before the windows of all the houses which fronted the street. Orders were issued to this effect in the year 1524, and again in 1526 and 1553. It will be remembered, if our recollection serves us rightly, that Mr. Preece, from the earliest introduction of the arc lamp, has again and again strongly urged upon municipalities the value of electric lighting, in that by its means more light is obtained, the streets are rendered brighter, and lawless individuals have thereby less chance of breaking the laws of the realm without being found out. He agrees, we presume, with most people in supposing that the moral attributes of man are in a rather low condition, and that many people would break the laws if they had no fear of being found out, and the best means as yet devised for repressing these law-breakers is to flood the whole place with light.

Paris commenced to light its streets with an apparatus called a *falot*, which seems to have been

Digitized by Google

a receptacle filled with various combustibles, till the year 1558, when these lights were changed for lanterns. Again, quoting from our authority, we find that "in 1667 the lighting of the streets of Paris was put on that footing on which it is at present." (The date of Prof. Beckman's book was 1846.) Up to 1671 the streets were lighted only during the four winter months, and on account of the numberless atrocities committed during the nighttime when there were no lights, the Parisians offered to contribute as much money as should be sufficient to defray the expense of keeping the lamps lighted throughout the whole winter." It will be unnecessary to follow this archæologic theme through the whole of its course—if any one of our readers desires to know what Prof. Beckman wrote he will find the article in the second volume of Beckman's history, issued in the Bohn Standard Library.

It will be seen that the early ideas were almost wholly connected with getting rid of the desperadoes who luxuriated in the darkness, following the old adage, that men love the dark because their deeds are evil. We prefer to add to this argument, and insist that we want more light, not only for the purpose hitherto described, but for the purpose of ordinary business. With the introduction of better lights, as every reader knows, without attempting a detailed proof, business and manufacturing purposes have been carried out during longer hours. There is no doubt that the introduction of gas was of incalculable benefit to all industrial operations, and we should incline to the opinion that the introduction of electricity will be quite as beneficial to these operations as was the introduction of the earlier illuminant. It must be remembered that the later illuminant only dates from, say, 1878, when Jablochkoff introduced his candles, and electric lighting was for a few years subsequent to this only seen furtively, and existed under no very happy conditions. From 1881, however, its progress has been rapid, and we are glad to see that there is every indication of its being still more rapid in the immediate future. Those who advocate the policy of progress so far as public lighting is concerned, then, would do well to add to their list of arguments in pushing forward their operations the one we have referred to, and to continually point out that more work and better work can be carried out in a given time with a better light, and thus the cost of the materials produced is lessened, and an indirect benefit arises which ought to be, but is not usually, taken into account.

CONGRATULATIONS.

We tender our hearty congratulations to the Metropolitan Electric Supply Company on the able way in which their engineers have enabled them to overcome the disastrous fire at their Sardinia-street supply station. On Monday evening last, at a quarter-past six, a fire originated in the dynamo-room. In under an hour the whole of the roof had fallen in, and the concrete floor was some six inches deep in red-hot ashes. By half-past eight the same evening the whole of the theatres and buildings most urgently needing light on the company's mains in that district were again receiving supply. The trunk mains from Rathbone-place, Manchester-square, and Amberley-road enabled this to be done. Still, when it is known that the switchboards by which such connections are usually made were at that time utterly destroyed by fire, the promptitude of the engineer will be duly appreciated. The mains are fortunately led into a chamber on the ground floor, which escaped the fire, and in this temporary cross connections were made from the trunk mains to the district supply mains. As, however, the trunk mains were installed with a view of supplying light loads only, they were of insufficient section to carry the total current required. On Tuesday afternoon the drawing in of further trunk mains was in full swing, and by to-night the whole of the consumers will receive light. In this operation, again, an unexpected difficulty occurred. The intense heat of the sun during the last two days had softened the tarry covering of the wires, making it very sticky to handle. In this way the drawing-in process has been greatly retarded. On Tuesday the Sardinia-street dynamo-room presented a lamentable appearance. The alternators had all suffered from the baking process, and the overhead traveller had fallen across two of them. Only a few stray connections stood to mark the spot where the switchboard was. The engines, being protected by the concrete floor, have not suffered much, and the boiler-room escaped entirely. Great credit is due to Mr. A. H. Walton for the energy with which he overcame the difficulties of resuming supply, and his whole staff have most ably risen to the emergency. We understand that the extension previously being pushed forward, by which alternators driven by steam turbines are to be placed on a floor over the boilers, will now be completed shortly, and we have no fear that the public will suffer any further inconvenience. Certain private consumers who had to give place to the public demands when only a limited supply of current was available will, we are sure, bear with the company, and will now congratulate themselves that the engineers of the company had made such good provision against total failure when designing the system of supply.

TELEPHONY.

We understand that the Select Committee which has been taking evidence on this question resolved at its meeting on June 25, in view of the political situation, to report the evidence it has taken to Parliament, and recommend the reappointment of the committee next session. This probably means shelving the question for the current year.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

THE USES OF ACCUMULATORS.

SIR,—The report giving the substance of my remarks at the recent meeting of the Northern Society of Electrical Engineers has been condensed by the omission of so many

Digitized by Google

important passages that I was hardly able to recognise parts of it.

It put words into my mouth regarding alternating currents which, when read without the other remarks which preceded and followed them, conveyed a totally false impression. I was at considerable pains to explain that the outcome of the long conflict which has raged between the advocates of continuous and alternating systems of supply has been to show that, however well suited alternating currents, whether monophase or polyphase, may be for power transmission or even for transmitting the energy for lighting purposes up to distribution centres, they are not well suited for employment in the distribution network—*i.e.*, from these distribution centres up to the consumers' lamps. That this was on account of those very peculiarities inherent in alternating or pulsating currents which, on account of the interesting problems involved, so endear them to the minds of professors and students, but which introduced practical difficulties in giving a perfectly regular and steady light free from pulsations.

I pointed out that the most successful way of dealing with these difficulties was to confine the alternating system to the transmission of energy up to the distribution point, to interpose the accumulators at this point, and consequently to use nothing but continuous currents in the network; and I pointed out that the very latest and best continental practice pointed in this direction.

All this matter, which was certainly given by me at as great a length as I have here written it, has been condensed by the report into five lines, in which I am made to say that I am strongly an anti-alternator man, and that alternating currents were no doubt a splendid thing in their way to professors and schoolboys, but nasty things to deal with in central stations.

I need hardly point out that such are not my opinions, and that I believe that alternating currents are playing and will play an important part in the electrical industry, and the brief summary of my opinions given in your "notes" is both unfair to me and misleading to your readers.—Yours, etc.,

R. E. CROMPTON.

Thriplands, Kensington Court, W.,
June 25, 1895.

INCANDESCENT LAMPS.

SIR,—In your issue of the 21st inst., your reporter has fallen into an error in stating that it was after the publication of the Swan *patent* that Mr. Edison abandoned platinum and adopted carbon in his incandescence lamp.

Unfortunately, the Swan *patent* was not applied for till after Edison's; but, as was shown at the trials in the law courts, lamps made by Mr. Swan and myself had been publicly exhibited in Newcastle and elsewhere before the date of Mr. Edison's patent of 1879; and if not in all respects quite up to the standard of the present day, they were at least better than any described in that absurd patent.

The question at issue in the courts was not whether the Swan *patent* was antecedent to the Edison, but whether the Edison patent was rendered invalid by the public exhibition of the lamps made at Newcastle and Rock Ferry by Mr. Swan and myself.

The result, as your reporter observes, was "*astounding.*"

Yours, etc.,

C. H. STEARN.

47, Victoria-street, Westminster,
June 21, 1895.

THE BURTON-ON-TRENT TENDERS.

SIR,—We notice in this week's issue you state that our tender for the cast-iron pipes for the extensions at Burton-on-Trent has been accepted. This, however, is hardly correct—our tender, which has been accepted, being for the high and low tension *cables*.—Yours, etc.,

THE TELEGRAPH MANUFACTURING COMPANY, LIMITED
(Per James Taylor, Director).

Britannia Telegraph Works, Helsby, near Birmingham,
June 22, 1895.

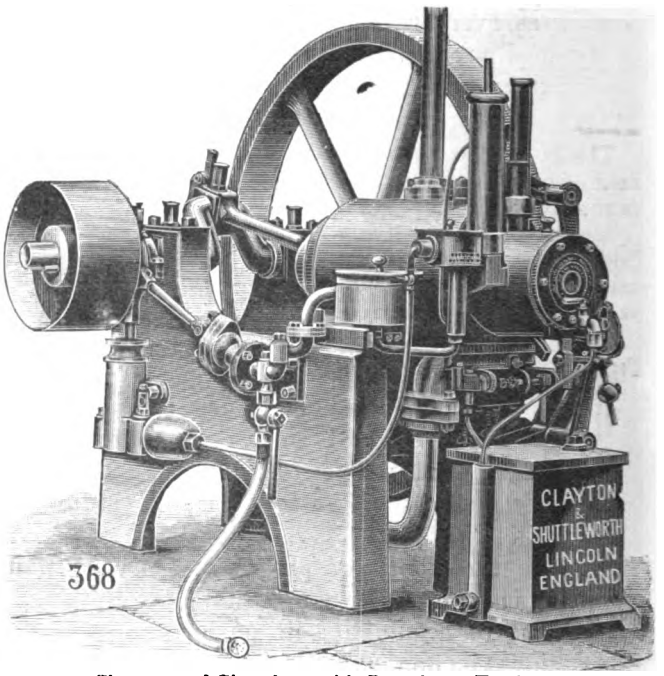
ELECTRICITY AT THE ROYAL SHOW.

Special telegraphic and telephonic arrangements had, of course, to be made in connection with the visit of the Royal Agricultural Society's Show to Darlington. Four Wheatstone instruments were connected with four special wires to the show ground, by means of which direct communication was established to London, York, Leeds, Birmingham, Manchester, Liverpool, Newcastle, Edinburgh, Glasgow, Aberdeen, and Dundee.

We understand that the postal and telegraphic business so far done considerably exceeds that of the corresponding period of the Cambridge show of last year. The telephone department was arranged by Mr. J. McKenzie, of Middlesbrough, manager for the Durham district of the National Telephone Company, whose acting representatives are Mr. A. T. M. Mushans, of Hartlepool, and Mr. J. T. Tattersall, inspector in charge, Darlington. The call office is situated near the Royal pavilion, and contains an efficient equipment of instruments, with switchboard for 12 lines, there being two trunk lines from the show ground to the exchange at Darlington. The public have the use of the call office, a charge of 3d. being made for communication with any part of Darlington.

There was a tolerably good exhibition of electrical machinery in the grounds.

Messrs. CLAYTON and SHUTTLEWORTH, of Lincoln, and 95, Queen Victoria-street, London, exhibit on Stand No. 7 a petroleum-engine (Knight and Weyman's patent) of 7 b.h.p., suitable for barn machinery, electric lighting, etc., of the type shown in the accompanying cut. This engine



Clayton and Shuttleworth's Petroleum Engine.

has been designed for using the common oils—such as petroleum and the ordinary lamp oils; the heavier oils can also be used. It acts upon the four-cycle principle—an impulse being obtained every other revolution—and it is fitted with a small oil pump and a vaporiser, the latter being placed at the end of the cylinder. The oil is contained in a small tank, which can be placed in any convenient position in the engine-house. The tank is connected by a pipe to the small pump, which is actuated by the governor of the engine.

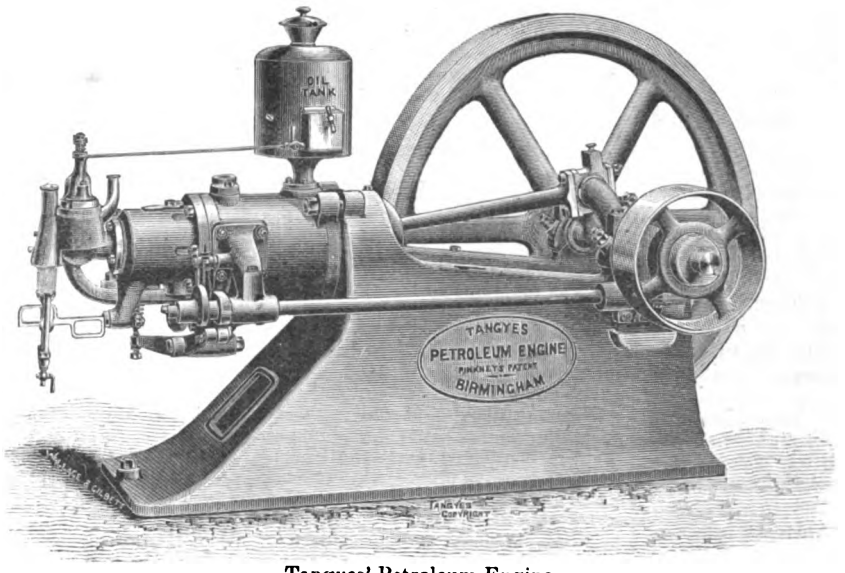
Messrs. GREENWOOD and BATLEY, LIMITED, of Albion Works, Leeds, show their electric motors of ¼ h.p., ½ h.p., and 1 h.p., the main features of which are: steel castings for magnets in all sizes, carbon brushes, and the ring method of lubrication. They show, further, an eight-unit dynamo, and an 8-h.p. motor driving an "Excel" pneumatic power hammer.

Messrs. JOHN FOWLER and Co., LIMITED, of Leeds, exhibit at Stand No. 107 an 8-h.p. semi-portable compound engine fitted with automatic gear on the high-pressure valve, specially adapted for electric lighting and similar work

Digitized by Google

where steady running is essential; and a 13in. horizontal engine fitted with automatic expansion gear controlled by the governor, and, like the foregoing machine, specially adapted for electric lighting.

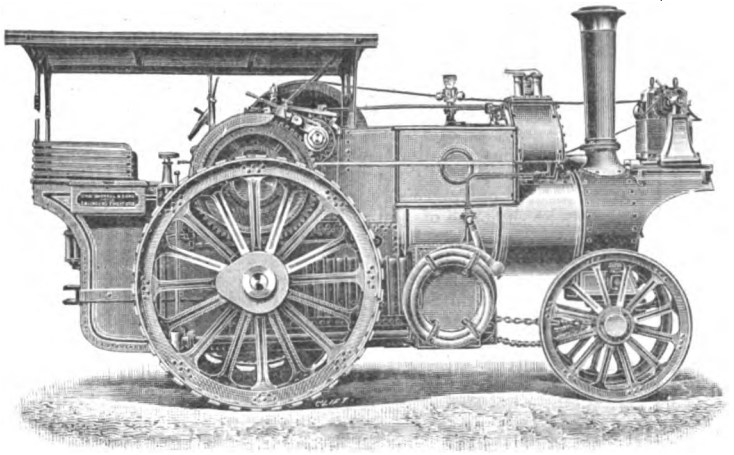
TANGYES, LIMITED, of Birmingham, have on view a 6 b.h.p. oil-engine driving a Siemens dynamo for electric lighting. This engine is built on the "Otto" principle, and is of simple construction, having only two valves—the inlet and exhaust. It has no fan for heating vaporiser, air or oil pumps, or air receiver. The explosion of charge is timed and effected by a small wickless oil lamp. The oil consumption under test at works is stated to be under one pint per brake horse-power per hour.



Tangyes' Petroleum Engine.

The HARDY PATENT PICK COMPANY, LIMITED, of Sheffield, show their well-known magnetic separator, for separating iron and steel from other material.

Messrs. CHARLES BURRELL and SONS, LIMITED, of St. Nicholas Works, Thetford, Norfolk, display one of their compound road locomotives, fitted with a dynamo in front, as shown in the annexed engraving.



Burrell and Sons' Road Locomotive.

Messrs. CROSSLEY BROS., LIMITED, of Manchester, display a special design of high-speed electric light engine, with extra heavy flywheel and out-end bearing, giving 28 b.h.p. (maximum) when working with coal gas; speed 250 revolutions a minute.

Mr. E. S. HINDLEY, of Bourton, Dorset, exhibits one of his dynamos and a high-speed electric lighting engine.

A METHOD OF ELECTRIC TRACTION FOR TRAMWAYS IN TOWNS—THE THWAITE-CAWLEY SYSTEM.*

BY GEORGE CAWLEY.

Any method having for its object the extension of efficiency and economy of transit, and put forward as a possible solution of a present difficulty, is, I may venture to presume, a matter suitable for consideration by the members of the Institute of Tramways of Great Britain and Ireland, as the mission of this institute is mainly connected with transit economy and efficiency, at least so far as the tramways of the United Kingdom are concerned.

Having this in view, and having also been kindly asked by your widely-esteemed president to read a paper before this meeting descriptive of a presumably novel method of electric tramway haulage recently patented by Mr. B. H. Thwaite and the writer, I thought I could not better show appreciation of the compliment paid me by your president than by readily complying with his request, even though I confine my remarks at the present time to a general outline of the scheme, leaving the most economical arrangement of the details for any given line as a matter for after consideration, and one which may, with the kind permission of your worthy president and council, form the subject of a supplemental paper on some future occasion.

There is not, I feel sure, the slightest need to make any kind of appeal to you with a view to convincing you either as to the practicability or advantages of electric traction on tramways. This being granted, then, the only questions really left for discussion are two—namely, first, which is the best electrical haulage method for any given line? for urban and suburban and outlying district lines demand treatment in accordance with their special requirements; and, secondly, how soon, having regard to financial and other preliminary difficulties, can our present horse haulage be supplanted by an electric haulage arrangement? The sooner this change can be put into practical form, the more speedily, as I hope to show, will the present not over-cumbersome profits made by owners of horse-hauled tramway lines assume a more satisfying and comforting proportion. That has been the general result in the United States after the conversion of horse-hauled lines to the electric system, and one may reasonably hope that a similar result would be effected in this country when suitable and well-considered urban and suburban electric methods have been fully adopted.

In confirmation of this, we have abundance of recent evidence, for within the last few months some thoroughly reliable information has been given on electric traction on American tramways by electrical experts who have studied the most recent developments on the spot. From this source we find that there are now some 600 electric tramways in the United States, operating nearly 9,000 miles of track and 20,000 cars. Also, that £45,000,000 has been already invested in electrical tramways, which now comprise nearly three-fourths of the entire tramway equipment of the country. This vast extension of the electric haulage system has been practically effected during the last five years. As in many other directions of industrial enterprise, the present state of perfection has been attained, to some extent, by a process of "trial and error," and "selection of the fittest" has been generally arrived at as a result of several years' working.

In many phases of industrial development, "John Bull" has been a pioneer, but as regards the subject under discussion he has wisely or unwisely lagged behind. As it often falls to the pioneer's lot to take a large share in "paying the piper," there may, perhaps, be some shadow of consolation in the present case in respect of the laggard action adopted so far by this country. We shall not, however, be able to comfort ourselves with that consolation much longer, except we also move forward and take advantage of the experience which the pioneering work of our American cousins, and also of our continental brethren, now affords us. From now we shall not even have left to us the excuse of commercial caution, for the financial success of the electric over the steam and horse hauled cars in America is proved up to full demonstration. A careful analysis of a large number of electric tramway accounts relating to continental and American practice has been recently made, with the result that the average working cost per car mile, leaving out only the item of interest upon capital, comes out as 6½d. in America and 5½d. in Europe. The ratio of working expenses to receipts, taking both Europe and America together, is approximately 60 per cent.

Comparing these figures with the corresponding ones obtained for our horse and steam tramways, we shall see that the latter are much higher, for the working cost per car mile for the latter comes out at about 10d., and the ratio of expenses to receipts

* Paper read before the Tramways Institute of Great Britain and Ireland.

Digitized by Google

over 80 per cent.—in fact, for the London tramways it was a short time ago 82·7 per cent., and in some few places elsewhere in this country over 100 per cent. The authority for the latter figures is "Duncan's Tramway Annual." Probably some little rectification may be required to bring them up to date, but I think I may assume that the figures given are not materially wrong at the present time, as they correspond with the figures for American tramways before the application of electrical power for haulage. For example, in the State of Massachusetts in 1888, at which time the whole of the tramcars in the State were either steam or horse hauled, the ratio of expenses to receipts was 81·07 per cent. In 1889 a commencement was made on these tram lines with electric traction, and by 1893 the ratio was reduced, as a consequence, to 69·26 per cent. Further, in 1888, the net earnings per car mile was only 2·78d., while in 1893 it was 4·82d. Again, the net earnings per passenger carried in 1888 were 0·48d., while in 1893 they were 0·78d. In 1888 there was throughout the State a total track mileage of 534 miles, while in 1893 the mileage had been increased to 874 miles, of which 711 miles were driven electrically. The foregoing figures, gathered from American practice, emphatically plead the cause of electric traction as regards this country, and all the more forcibly when it is recollected that the decrease in the percentage of working costs to gross receipts was effected in American practice at a time when large investments had to be made for electric plant to displace the former plant, and that the value of the old plant had to be materially discounted or written off altogether. As bearing on the development of tramway enterprise on the other side of the Atlantic, it may be mentioned that Boston, with a population of only about a tenth of that of London, has over twice the number of cars in operation. In fact, it can boast of having the largest tramway equipment in the world.

Enough has been given to show that we have plenty of ground to make up if we wish to place ourselves on a level with electric tramway enterprise in America. If it be granted that this is desirable, we have, as a first consideration, to decide which is the most suitable method to adopt, and this opens up a large question. The salient points which govern the selection of a system vary, of course, not only with the district, but with the country in which the given line is to be built. For example, the electrical haulage methods allowed and adopted in American cities would not be generally permitted on similar lines in this country. The overhead single-trolley system, almost universally adopted in American towns—the so-called "deadly trolley" of the American newspaper reporter which caused an immense scare, and also several deaths, a few years ago—would not be generally accepted by the local authorities in our large towns, evidence of which we see in the action of the London County Council. When the matter was discussed by this important body on January 29 last, a large majority decided against the overhead system in the case of the West Metropolitan Tramways. In this discussion Mr. John Burns referred to the overhead system at Leeds, and said that he had noticed there "more kitetails entangled in the wires than he should have thought it possible for any community of boys to have produced in 50 years."

In the case, then, of lines in our large towns we should probably be compelled to adopt either the conduit or the storage battery system—that is, we must either derive our supply of electric energy from below ground or carry a supply of it in accumulators on the car. Only a short time ago, Dr. Preller, in a valuable paper on electric traction read a few months ago, stated: "It is not generally recognised that the overhead trolley system—much as it has been improved—is in reality only a makeshift, and is unsuited for the central parts of large towns. In these cases the conduit system or accumulator cars are therefore at present the only practicable solution of the problem. In Europe, the conduit system, whether it be that of Budapest or with a central slot, may be estimated to cost complete at least £10,000 per mile of single line and upwards, according to local conditions, though this is not too costly having regard to the enormous traffic in large towns; but its efficient working presupposes, among other things, perfect drainage of the trench. As regards accumulator cars, they would really constitute an ideal form of electrical tramway traction in towns, if the present weight of 12 to 15 tons, and the power and traction expenses of 8d. to 10d. per car mile, could be reduced to one-half."

As regards the latter method, it is fairly simply applied without disturbance of the line, but, for reasons of working cost alone, it does not appear to be the method which will be permanently adopted in English practice, except accumulators can be improved and lessened in weight. We then have the conduit, or culvert, system, and this is, no doubt, a relatively costly system to construct; but on account of the scope it gives for embodying practical solidity and durability in the working details, and to the convenient disposition of the conductors below ground, it is, I venture to think, the system that will be chiefly adopted for tramways in towns where electric haulage is used.

Although the conduit system has been adopted in several places in the United States and on the Continent, there is only one example of this system in this country—namely, the line at Blackpool, erected some years ago by Mr. Holroyd Smith. It is only fair to Mr. Smith to state that the Blackpool line is a very creditable piece of pioneer work. It was constructed at a time when practical experience was wanting as regards the electric system of haulage, and the constructor had to rely on his own experience as an engineer for guidance as to the practical fitness of the details embodied in his scheme.

With regard to the success of the conduit system so far as it has been applied, the opinions even of experts widely differ. One American expert, in referring to the conduit systems erected in the United States, stated a short time ago: "There have been in this country at least four practical experiments with conduit rails, and several hundred thousand dollars have been expended in testing them. In spite of all this refinement and study, practically nothing has been accomplished, and I have no hesitation in saying that the continuous-line conductor in an open-slotted conduit is to-day a failure, its fatal weakness being our inability to prevent the conduit from becoming filled with water, mud, etc."

(To be continued.)

LEEDS TRAMWAYS.

A report of the Sub-Highways (Tramways) Committee to the Highways Committee of the Leeds City Council, of their investigations as to tramway traction, and recommendations thereon, has just been issued, which contains a good deal of interesting information.

The sub-committee was first appointed by the Highways Committee on December 13, 1893, by the following resolution: "That a sub-committee, consisting of the chairman, deputy-chairman, Aldermen Ward and North, and Councillors Mart, Hannam, Metcalfe, and Boston be appointed to take cognisance of all matters connected with the transfer to the Corporation of the Leeds tramways undertaking and the temporary working thereof by the Corporation; also to consider the future working and mode of traction to be adopted." It was reappointed on November 12 last and now consists of Aldermen Firth, Hepworth, Scupham, and Ward, and Councillors Boston, Carter, Denison, Goodson, Hannam, Henry, Mart, and Moody. The undertaking of the Leeds Tramways Company was formally taken over by the Corporation on February 2, 1894, and since that time the purchased tramways have been worked by the Corporation pending a decision as to the motive power of the future and the necessary relaying of the lines consequent thereon.

The tramways purchased by the Corporation from the Leeds Tramways Company, reckoned as single line, are 22 miles. In addition, the Corporation own the Roundhay and Beckett-street tramways, amounting to five miles. The total length of lines (single track) laid and to be laid is 42 miles.

Before the sub-committee was appointed, a deputation from the Corporation visited Birmingham and inspected the four systems of haulage in operation there—viz., cable, electric (accumulators), steam, and horse. The various lines and the respective power stations were visited, and the deputation noted the advantages and disadvantages of the various systems. The horse and steam departments have similar features to those in Leeds, both as to cost and income. The accumulator electric system is very far from a success commercially, and the sulphuric acid in the accumulators at the time of the visit gave out a disagreeable smell to the passengers. This, however, it is claimed, has long since been obviated, and that it is not a permanent feature of the running, nor indeed a necessity of the case at all.

In the months of September and October, 1893, first the sub-committee and then the General Committee inspected the electrical overhead tramways at Darlaston and Walsall, the property of the South Staffordshire Tramways Company. The system differs from that of the Thomson-Houston Company, as established in Roundhay-road, in the fact that the posts and wires are on one side of the road only, with one wire for single track and two for passing-places and double lines. The promoters claim this feature as superior to the corresponding part of the system of the Thomson-Houston Company. This claim seemed to be a just one, as no wires crossed the streets, and many less guy wires were required to pass round corners. The tramway company equipped their lines originally with steam-engines, but having received an intimation from the Corporation of Walsall that a renewal of their license to use steam would be opposed, the company deputed their general manager and engineer to visit America, and there learn the facts as to the cable and electric overhead systems of haulage. The result of this visit was that the company entered into an arrangement with the Electric Construction Corporation to equip their lines with the electric overhead system. By this arrangement the tramway company were not to pay the whole cost of the installation, and the running was to be done by the Electric Construction Corporation, and on both accounts the company agreed to pay a total of 9d. per car mile for a period of five years. This amount has since been reduced, pending a decision of the law courts on questions which have arisen between the two companies. On this system, a very noticeable feature is the double decked cars, small single cars being the custom in other countries. Your committee were very pleased to have this demonstration of a double-decked car being used.

In June last, the sub-committee visited Newcastle, where there are 14 miles of tramway (taken as single track). The Newcastle

Digitized by Google

Corporation have such a very determined objection to the wires and poles of the overhead electric system, that in giving their instructions to their engineer to report they excluded even the consideration of the overhead system, of which, therefore, your committee could not here glean any information.

The sub-committee visited Glasgow, where the Glasgow Corporation, in view of the working of the tramways falling into their hands, have fully considered the subject of tramway traction, including horse (the only haulage now used by them), compressed air, oil, and gas, as well as electric and cable. Their general conclusion appears to be that horse haulage should be discontinued as soon as possible, that compressed-air, oil, and gas motors have not to the present time been so far perfected as to make their adoption practicable, and that as between cable and electricity they say their town is well suited for cable, that overhead electricity would not suit them in the heart of the city on account of its unsightliness, though it might do in the outskirts. They have not arrived at a definite opinion as to the respective merits of cable and overhead electric traction, believing, however, that each has a merit, and that the special circumstances of the tramway routes must be carefully considered before determining which system should be adopted. The Corporation have been working their tramways since July 1 last. It has been a very large addition to the labours of the Corporation.

On August 29 last, the sub-committee visited the Isle of Man and inspected the tramways there, which belong to the Isle of Man Tramways and Electric Power Company. They consist of a line of horse tramways along the promenade at Douglas about two miles in length, and a double line of electric tramways seven miles long, being 14 miles of single track. This system is overhead, but instead of the trolley a collector bar is used on each end of each car, the patent of Dr. John Hopkinson. It is, in fact, a railway and not a tramway, and is placed wholly on land belonging to the tramways company abutting on the road from Douglas to Groudle but not so abutting from Groudle to Laxey, though crossing in two or three places. An important feature of the Isle of Man electric traction is the "cut-out" switches which are provided at certain points along the line, about three-quarters of a mile apart, with the result that in case of a breakdown by failure of current, etc., the section between the two cut-outs only is affected. There are two generating stations—one at Douglas and one at Laxey, being at each end of the route. Another speciality of this line is the accumulator station at Groudle, which contains a battery of 240 cells. From this station 100 e.h.p. can be supplied for 4½ hours, or 50 e.h.p. for 10 hours. Sometimes the company have supplied as much as 150 e.h.p. for a short time from this station. The cells are always automatically charging or discharging according to whether the generating station is making sufficient electricity or not for the motors running on the lines. This arrangement of storing surplus power enables the company to run their stationary engines and dynamos at nearly full load for the whole of the day, and in this regard effects a saving in the consumption of fuel. The cells are of a new type (the chloride), and it is claimed for them there is only a loss of electricity of about 20 per cent., and that this is more than covered by the increased saving in coal and wear and tear of plant.

At Brussels we found a very complete and well laid out sample of the Thomson-Houston overhead system. There are two lines electrically operated, having a total length of about 19 miles, and a total of 35 motor cars, each one of which takes a trail-car. Before the introduction of the electric system, a large portion of the line was worked by steam; and although the municipal authorities at Brussels opposed very strongly the introduction of the overhead wires, yet the Belgian Government and public opinion caused them to give way, and the satisfaction now given is very great. Along the route the difference is very marked. With the steam locomotives, the smoke, coal dust, and condensed water made the route most unpleasant. Now the state of things is very different. Inside the town itself the overhead wires are mostly fixed on steel posts with arms carrying the trolley wire, so that there is very little cross suspension. Outside the town, in places, wooden posts are used. The trolley wire is cut into sections electrically so as to separate each quarter mile. This is a great convenience, and enables repairs and other work to be done without affecting the general working of the line, and is of much importance in case of fires along the route. The feeders are carried under the ground and are tapped into the trolley wire at frequent intervals, thus keeping the pressure very constant. Lightning arresters are used along the line, and have proved useful in several severe storms. The electric system fulfils the requirements of the public much better than the steam trains, which consisted of four or five cars making a journey every half-hour. At present the electric cars run every 15 minutes in each direction. In the city itself the service is much more frequent, cars following one another at intervals of four minutes. The increase of traffic since the lines have been opened we are informed is very considerable, amounting to 100 per cent. Along parts of the road the speed reaches 16 miles an hour, and the gradients are steep, amounting in one case to 1 in 16. There are two generating stations. In one there are three Babcock and Wilcox water-tube boilers, with three Macintosh and Seymour engines, and three Thomson-Houston generators, 100 kilowatts (133 e.h.p.) each; water for condensing is obtained from the Seynne by an underground canal 250 yards long. In the other generating station there are also Babcock and Wilcox boilers, Macintosh and Seymour engines, and five Thomson-Houston 100-kilowatt (133 e.h.p.) generators, with room for three more units. Water for condensing not being convenient, this generating station is running non-condensing. The actual cost of traction (power and maintenance) is 1·79d. per car mile for one concern and 2·78d. for the other.

In Paris the tramways are worked by compressed air and accumulators. These are most expensive systems, and the compressed air has the additional drawback of having a very large, ugly, and heavy engine and car combined.

At Havre is one of the most complete examples in Europe of electric traction on the Thomson-Houston overhead system. The whole of the network of the Havre trams, originally operated by horses, is now electrically equipped. We found nine miles actually in work, and extensions were already in progress. This nine miles is largely double track, and is equivalent to 15 miles of single track. The gauge is 4ft. 8½in., the steepest gradient is 1 in 23, and the smallest curve has a radius of 58ft. 6in. There are 40 motor cars each divided into first and second class, and each car has a carrying capacity of 50 passengers. The cars are fitted up in very good style, and the electric equipment is of the latest Thomson-Houston pattern. The speed and direction are well under control from either end of the car. They run smoothly and quietly, and are lighted electrically. The overhead line is a good example of this class of work. In the narrow streets the wires are suspended over the track by cross-wires of steel, fixed in some cases to ornamental brackets let into the walls of the house, and in other cases by steel posts. In the broader boulevards there are centre posts with ornamental arms on each side carrying the trolley wire, and electric lamps are placed on the top of every other post. The effect is extremely good. The posts are 29ft. long, sunk into the ground 6ft. 6in. They are made in four sections of steel tube, the joints being covered by cast-iron rings, and the base fitted with an ornamental casting. There are about 560 posts. Of this number, 85 have arc lamps on them lighting about 4½ miles of thoroughfare. We understand it is likely that the number of arc lamps is shortly to be increased. The generating plant is situated in the central station of the local electricity supply company, with whom the tramway company have made a contract for the supply of electric energy. The generators consist of three four-pole Thomson-Houston dynamos of 200 kilowatts (266 e.h.p.) each, at a pressure of 500 volts and a speed of 425 revolutions. The machines are over-compounded 10 per cent., so that the pressure on the feeders is maintained constant at 500 volts. The generators are each rope-driven by a Corliss-type condensing engine, running at 65 revolutions. Sea water is used for condensing, obtained from one of the docks. The car-shed is a fine erection, 63ft. in breadth and 225ft. in length. This will accommodate about 60 cars, and the entire movement of the cars is effected electrically. A repair shop is arranged in proximity to the car-shed, and the tools are all electrically operated. The equipment of the lines has only recently been completed—viz., in July last—but already in September the number of passengers carried was double that in the corresponding month of the previous year, when horse traction was used, and we understand that the contractor's guarantees as to running costs were more than realised. The actual cost of traction per car mile is 3·37d., and the receipts 11·2d.

The fitting up of the Roundhay tramway with the electric overhead system of haulage is the result of a concession from the Leeds Corporation to Mr. Graff-Baker, the representative at that time of the Thomson-Houston Company, but that gentleman has now for some time ceased to have any connection with the tramway, and it is worked by the British Thomson-Houston Company. The installation consists of a generating station at Burmantofts, where engines and dynamos are placed capable of giving out 130 effective horse-power. The electrical horse-power required for a whole working day averages 10 per car. There are five cars running. Each of the cars is fitted up with two 15 h.p. electric motors. The difference between the actual horse-power required to work a car and the horse-power fitted to a car is caused by the power required to start the car on the severest gradient. This difference also accounts for the generating power at the station having to be so much in excess of the average requirements of the cars. This drawback has been lately largely surmounted by improvement in the electrical machinery on the cars. The weight of the motor car is 6½ tons. Those now being built are five tons. On busy days the motor car commonly pulls a trailer car. The whole of the wires are overhead, supported by poles placed against the edging stones. They run about 7½ minutes' service. The installation commenced to run on October 29, 1891. Since that time not a single wire has been broken or an accident or inconvenience suffered by anyone by reason of the installation being an electric one. The accounts, in accordance with the terms of the concession, have been regularly audited by the Corporation auditor. It is claimed for this tramway that, like all other electric overhead installations, the traffic has increased more than it would have done by any other system. For the year ending November 10, 1892, the passengers numbered 720,069; from November 11, 1892, to August 28, 1893, the passengers numbered 659,376; and for the year ending August 28, 1894, the passengers numbered 931,055.

The sub-committee having thus obtained what information they could from other towns, and considered their detailed memoranda made during their visits, instructed the city engineer himself to consider the whole subject, both from the scientific and commercial point of view, and to submit to them his report thereon. This he has done, and a print thereof is appended hereto. The sub-committee have since met several times to consider it. The plan of this report leaves out of the question the incomes of the different systems.

As to the estimated price of the land for depôts, and as to the fact that a much higher price is put down for the central cable depôt than for the overhead electric depôt, it must be remembered that the former of necessity must be very centrally situated, whilst the latter need not be so, and looking at the sites available we think

Digitized by Google

the prices in the estimate are reasonable and are just as between the systems. In regard to the indicated horse-power required as plant by the cable system, we find that, comparing it with the three cables working in England and providing a reasonable stand-by, the amount provided in the estimate is certainly not in excess. In Birmingham, for six miles, the average amount required is 180; in Edinburgh, for 5·4 miles, the average amount required is 130; in Brixton, for 5 5 miles, the average amount required is 220. The difference arises from the varying services, gradients, and angles. In the winter months, with snow and frost, the horse-power required is much greater than this. As to the same item for the electric overhead, we have had the actual electrical horse-power being used at Roundhay measured, and find that on a bad day for working the average amount required is 12·7 e.h.p. per car, whilst for a fine day it is only 6·7 e.h.p. As to the motor cars, there having been different statements made as to their weight, we have had one weighed and find it is 6¼ tons, and not 9½ tons. We are informed the motor cars now being built are only five tons. Taking for safety the present cars on a bad day as a basis, the 69 motor cars and seven trailer cars of the system dealt with by the report would only require an average of 920·75 e.h.p. to work them, and adding to this 25 per cent. for indicated horse-power and 450 i.h.p. as a stand-by, the total average indicated horse-power required would be 1,600. The indicated horse-power debited against the electric overhead is, however, 2,175, the difference being an allowance for fluctuation of load. Having regard to the more uniform demand for power that the 35 miles of our full tramway system will make compared with the smaller five miles of the Roundhay-road electric overhead tramway, and taking into account the great mechanical improvement made as to the fluctuations of the power required by each car, we are of opinion that the indicated horse-power debited against the electric overhead system is rather in excess of the requirements of the case than otherwise. As to the cost of engines and buildings, the engineer submitted the capital accounts as published of the House to House Electric Lighting Company. The total indicated horse-power of that company's installation being 1,800, as against the 2,175 i.h.p. of the electric overhead and the 1,200 i.h.p. of the cable system, your committee accept this basis as a sound one, preferring such an excellent guide to any estimate based on general, although professional, knowledge. As to the cable conduit, the price has been determined by a detailed estimate of the engineer. The engineer pointed out that his figure was less than the amount the cable conduit had cost in the other cases, but claims that the Leeds Corporation can do this cable work at the price named. As to the street work of the electric overhead system, that also is based on the engineer's estimate, which, however, whilst taking all wires except trolley wires as placed in iron pipes underground, places high rates on each item; and comparing the figures with those given in public papers, we think this estimate sufficient. As to the cars, in both systems the prices stated for the electric overhead are those of several years ago. There is no patent to prevent their being made by anyone, and your committee believe electric double-decked cars can be built at the price stated in the engineer's estimate.

The committee believe that a full tramway service will increase the number of passengers. Indeed, it is claimed that the ease and comfort of the electric cars at once increase the number of passengers. Be that as it may, should the service ultimately given be less than that assumed in the engineer's report, the alteration would be in favour of the electric overhead system and against the cable system. The engineer's provision as to capital account is, with a slight exception, the same in all cases. The capital account for land, buildings, and tramway track is to be paid off in 30 years, and for machinery and rolling-stock in 20 years. The exception is as to the electric motor cars. These—*i.e.*, the carriage proper, as well as the electrical machinery upon it—are taken as having an average life of only 10 years. In the case of renewals on all systems the same terms of years are given, and the same exception occurs against the electric overhead. It appears the payments for capital and renewals on account of these cars is put down at £11,800 per annum. We are struck with the severity of this charge, and believe that in practice the average life of the two parts of a car will be found to be much longer than 10 years, in which case the electric overhead system will give a greater saving than appears in the report. As to the other terms of years, the sub-committee believe them to be readily obtainable, particularly as the question of repayment by the London Vestries of capital expended on electric lighting stations has just been settled on easier terms than those in the engineer's estimate, after a thorough examination of the question by the London County Council, in conjunction with the Treasury. The terms agreed are 50 years for land, buildings, etc., and 20 years for machinery and all other purposes.

The price per car mile has been arrived at as follows for the electric overhead system. Although the company operating this system has not published its accounts, it is important to remember that the agreement between the Corporation and the company enables the Corporation to examine the books of the company, and that this has been done, and the following figures can therefore be accepted as most reliable: the Roundhay electric tramway for the last 12 months, with a seven to eight minutes' service has cost 5·76d. per car mile. The management and power station expenses included in this amount are ·71d. and ·65d. per car mile respectively. In the large installation contemplated this will be reduced ·21d. and ·32d. respectively, and the cost would then be 5·23d. car mile. Adding to this the ordinary repairs on 35 miles single track, at £50 per mile, and on 2,429,084 miles = ·17d. per car mile, the total cost per car mile becomes 5·40d.

After considering the engineer's report most exhaustively, and comparing it with the notes previously made by them, and reviewing the whole case, the sub-committee have come to the conclusion that the present dual system of haulage—viz., by steam and horse power—should be superseded; that oil, gas, and compressed air are at present impracticable; and that having regard to the many routes in Leeds, and the great length of each involving varying requirements as to frequency of service, and the fact that really steep gradients are here uncommon, they are unanimously of opinion, and recommend to the Highways Committee, that electrical traction is most suitable for the tramways of this city. They have not failed to consider the advantages of cable where the gradients are commonly steep and the streets mainly narrow, nor that cable is specially remunerative where the routes are short and thickly populated, thus rendering a frequent service practicable on all the lines equally, but these advantages only apply to Leeds to a very limited extent, and, on the whole, the committee's preference is decidedly in favour of electric traction, with overhead wires except in the centre of the city, say, from the junction of Briggate with Boar-lane to the dispensary in North-street, to the junction of Hunslet-lane with Hunslet New-road, to Queen-street in Wellington-street, and to the top of Park-row, and that within these limits an electric conduit system should be adopted. The sub-committee do not close their eyes to the fact that objections may be made to both the overhead and conduit systems of electric traction, and that it will no doubt be contended by some that the former will seriously disfigure the streets. This, however, is not considered an insuperable objection, and, moreover, it is believed that great improvements can be made in regard to them by reducing the number of wires overhead by placing the feeder wires underground (already provided for in the estimate), and also by dispensing with many of the poles by fixing wires and apparatus to buildings (power to do which is being asked for in the Bill before Parliament), and possibly by placing such poles as are necessary against buildings (instead of at the causeway edge) in some cases, and in other cases in the centre of the roads rather than on both sides thereof. At the same time it may be practicable to utilise these posts for electric lighting by arc lamps, greatly to the advantage of the districts in which they may be placed. Overhead electric traction will also avoid the danger to vehicular traffic caused by the extra metals required to form the slot along each of the two tracks for cable traction, it being impracticable in many parts of the city to allow the width of two passing vehicles on each side of the tramway. This difficulty will not, of course, be removed where the conduit system of electricity operates, which, however, would only cover about 2¾ miles in the centre of the city, where the streets are fairly level and of good width, out of the total of present and intended tramways of 41 miles.

The sub-committee would refer the Highways Committee to the engineer's report, which deals in detail with the commercial and practical advantages of the electric overhead system over the cable as it affects Leeds, with whose observations and conclusions they concur, but they do not consider it necessary to lengthen their report by repeating them. The sub-committee believe that the difference in the annual cost of the two systems will be more, rather than less, than that estimated by the engineer, but accepting his figures, find that, taking into account the 13 miles (single track) of tramways being applied for this parliamentary session, and not included in the engineer's estimate, the difference in annual cost between the cable system and the overhead electric system, combined with a central-conduit system, will be £13,880 in favour of the latter.

In addition to this, the sub-committee would specially point out that whilst they are of opinion that the electric overhead system has passed the experimental stage, its possible advantages have doubtless not yet reached the maximum. Improvements are anticipated in regard to the accumulator system. These, however, seem remote, but should they be successful, that system would be preferable to the electric overhead system. The sub-committee believe that electricity in some form will be the motive power of future tramways, and that therefore it is a matter of considerable importance to note that not only will the capital expenditure upon overhead electric traction be much smaller than upon the cable system, but that in case of alteration, or the subsequent adoption of a new method of electric traction, less loss will result in its adoption than would be sustained by a change from cable haulage to that of any other.

Engineer's Report.

Mr. Thomas Hewson, the city engineer, in his report says:

In accordance with your instructions I beg to submit a report on the various systems of tramway haulage. The systems which have been adopted are horse, steam, cable, and electric. The systems that have been put upon the market, but so far not adopted in this country, are oil-engines, gas-engines, and compressed-air engines. The latter power is in use in France, and gas-engines have just been installed in one of the German towns.

Looking at the many trials and many failures of compressed air as motive power, I dismiss it as one not to compare with the remaining three systems—viz., the present combined system of horses and steam-engines, the cable, and the electric, the latter being divided into three modes—viz., the overhead, the conduit, and the accumulator.

With an installation practically entirely new, and with practically double lines throughout, Leeds would have the smallest capital account per mile of route of any large town in England; and having previously eliminated from consideration all systems but cable and electricity, I now proceed to a comparison between these systems of haulage by ascertaining first, the capital, and second, the annual sum required for each, premising that it wil

Digitized by Google

be found these estimates do not propose to utilise the spare heat at the refuse destructors, and that my reason for this is that even supposing the whole cost of fuel could be saved by utilising this heat, the saving would amount to less than the gain of having the electric overhead system at one central station, or the cable system at a minimum number of stations, and all of them in the right situation for coal, water, and economical working.

As to the various modes of the electric system, I think it is common knowledge that the accumulator and conduit modes have heretofore been so costly as to be prohibitive, and even to-day the accumulator mode, although the most desirable from the fact of its being self-contained and so requiring no fixed provision above or below the surface of the streets, is unfortunately still out of the market financially. Notwithstanding the many patents which have been taken out within the last few years, the cost per car mile is nearly double that of cable and of overhead electric at a 7½ minutes' service. It would therefore be a waste of time to give an estimate of its cost As to the conduit mode of electricity it is palpable it must cost more than the overhead mode, as, in addition to all the expenses which that mode has, it has the conduit to provide. Taking the cost of the Budapest tramway at £14,750 per mile of single track—which is the amount the official documents show to be the cost, and seeing that the cost of labour on the Continent is cheaper than in England it is certain the cost in England will be no less—this it will be found is £3,936 per mile more than the overhead electric mode would require, and on the Leeds mileage this would amount to a total of £137,760 of extra capital outlay. This fact, together with the difficulties attending the conduit mode, and absent from the overhead mode; the extra loss of power by leaks and short circuiting; the objection to a wide slot in the roadway; the great cost of cleansing the conduit to prevent short-circuiting; and the interference with the traffic by the frequent repairs, I consider also places this mode out of the running. I am now left with only the overhead mode of the electric system to make an estimate for to enable me to make a comparison between it, the present system, and the cable system—the only three systems now surviving in this report.

Estimate of cost of Leeds tramways, installed with electric overhead system of haulage, including remodelling, doubling the lines where single—except Beckett street, which is to be extended as single line to York-road—buildings, plant, and equipment necessary for a 7½ minutes' service, which, with overlappings will give services of 3¾ to 1⅞ minutes in the centre of the city:

12·05 miles of double track of overhead electric road construction (all feeder wires to be laid in pipes under footpath, and return leads under tracks), at £1,900 per mile of double track		£22,900
5·414 miles ditto ditto, including taking up and relaying pavement, at £2,050 per mile		11,100
1 mile of ditto ditto, single track, Beckett-street and Burmantofts-street, at £1,500		1,500
77 cars with electric motors, complete, to carry 52 passengers, at £750		57,750
2,175-i.h.p. engines, boilers, dynamos, and fittings for 69 running motor cars, at 30 i.h.p., and 7 trailers, at 15 h.p., at £15		32,625
Buildings, sheds, offices, etc., for 2,175 i h.p., in one central station, at £6 (present sheds to be used for car storage)		13,050
3,000 yards of land for central station, at £2		6,000
		144,925
Cr. by six 'buses, at £20	£120	
Cr. by 62 cars, at £15	930	
Cr. by 380 horses, at £20	7,600	
Cr. by 380 sets of saddlery, provender, etc., at £2	760	
Cr. by 25 steam-engines, at £250	6,250	
		15,660
Total amount required for installing electric overhead system over and above first cost and cost of remodelling tramways		129,265
First cost and cost of remodelling present tramways, including buildings and equipment		249,234
Total first cost and cost of remodelling present tramways on electric overhead system, including buildings and equipment, up to 7½ minutes' service		£378,499

Collecting the three estimates:

The capital involved in remodelling the present tramways, and bringing them up to a 7½ minutes' service, on the present system is	£265,884
Ditto ditto, and in installing electric overhead system	378,499
Ditto ditto cable system	428,922

If the relative capital sum involved afforded a complete answer to the question of what our future system should be, clearly we should make no change, as the present system would involve the least capital. But it does not. The complete answer from the financial standpoint is not found in the system employing the smallest capital sum, but in the one which would involve the ratepayers in the smallest annual cost. The capital involved is in inverse ratio, though not uniformly so, to the annual cost. This un-uniform ratio of annual cost to capital involved, arises out of the fact that the works and plant on which the larger capital sums are expended are of varying degrees of permanence, and as such have to be repaid more or less rapidly than the system involving a smaller capital outlay. On the other hand, this larger expenditure on less permanent works often makes it possible to work at so much smaller a car mile cost as that it more than repays the increased annual liability arising from the larger capital account. In a word, a small capital expenditure means larger working expenses than the systems involving large capital expenditure.

Applying, therefore, this test as conclusive on the financial point, but premising that not only will the Corporation, like any private company, have to pay interest and provide a depreciation fund for renewals, or, what is the same thing renew out of revenue, but, in addition, the Corporation will have to repay the principal in a limited number of years, and that the two payments together will be, though not much more, still slightly more than a private company would have to pay who distributed amongst its shareholders a 5 per cent dividend. With this premise, I find the annual cost to the ratepayers of the present, the cable, and the electric overhead systems of haulage will be as follows:

Annual cost of working the Leeds tramways on the present system, with lines remodelled as before described, and with the additional rolling stock, etc., for a 7½ minutes' service in the outskirts, and a 3¾ and 1⅞ minutes' service in centre of city:

	£	£
Interest and sinking fund at 3 per cent., and repayment of capital in lines, buildings, and land, in 30 years—*i.e.*, 5·1 per cent. on	216,236 =	11,028
Ditto, ditto, at 3 per cent. and 20 years—*i.e.*, 6·75 per cent. (for horses, machinery, rolling-stock, etc.), on	49,648 =	3,351
	£265,884	
Renewing 35 miles of single track of tramway at £3,093 per mile amounts to £108,255. To raise this sum in 30 years by equal annual payments invested at 3 per cent. interest requires		2,275
Renewing rolling stock in 20 years by equal annual payments at 3 per cent. interest:		
25 engines at £800	£20,000	
25 bogie cars at £200	5,000	
59 horse cars at £150	8,850	
	£33,850	1,260
Expenses working 22 steam cars, running 18 hours per day, at 7½ minutes' interval, and nine hours on Sundays = 774,490 steam car miles at 10½d.		33,884
Expenses working 47 horse cars, as per steam working = 1,654,594 car miles at 9½d.		65,494
Present system total annual cost		£117,292

Annual cost of working the Leeds tramways on the cable system, with lines remodelled as before described, and with rolling-stock, etc, for a 7½ minutes' service in the outskirts, and 3¾ and 1⅞ minutes' service in the centre of city:

	£	£
Interest and sinking fund at 3 per cent., and repayment of capital in lines, buildings, and land in 30 years—*i.e.*, 5·1 per cent on	361,644 =	18,443
Ditto, ditto at 3 per cent. and 20 years—*i.e.*, 6·75 per cent. on machinery, rolling-stock, etc., on	67,278 =	4,541
	£428,922	
Renewing 35 miles of single track of tramway and slot rails to conduit, at £4,293 per mile, amounts to £150,255. To raise this sum in 30 years, by equal annual payments, invested at 3 per cent. interest, requires		3,158
Renewing rolling-stock in 20 years, invested at 3 per cent. interest, on		
84 gripper cars, at £250	£21,000	
Machinery, etc.	27,450	
	£48,450 =	1,803
Expenses working 69 gripper cars, running 18 hours per day and nine hours on Sundays, at 7½ minutes' interval = 1,198,336 car miles, at 8·37d.	41,792	
Ditto, ditto, at 3¾ minutes' interval = 787,890 car miles, at 6·58d.	21,601	
Ditto, ditto, at 1⅞ minutes' interval = 442,858 car miles, at 5·68d.	10,481	
		73,874
Cable system, total annual cost..		£101,819

Annual cost of working the Leeds tramway on the electric overhead system, with lines remodelled as before described, and with rolling-stock, etc., for a 7½ minutes' service in the outskirts, and a 3¾ and 1⅞ minutes' service in centre of city:

	£	£
Interest and sinking fund at 3 per cent., and repayment of capital on lines, buildings, and land, in 30 years—*i.e.*, 5·1 per cent., on	228,086 =	11,632
Ditto, ditto, at 3 per cent. and 20 years—*i.e.*, 6·75 per cent. (for machinery, rolling-stock, etc.), on	92,663 =	6,255
Ditto, ditto, at 3 per cent. and 10 years—*i.e.*, 11·725 per cent. (for motor cars)	57,750 =	6,771
	£378,499	
Renewing machinery and electric construction under and over road in 20 years, invested at 3 per cent. interest, on	92,663 =	3,448

Digitized by Google

Renewing 35 miles of single track of tramway, at £3,093 per mile, amounts to £108,255. To raise this sum in 30 years by equal annual payments, invested at 3 per cent. interest, requires		2,275
Renewing motor cars in (average of machinery and car) 10 years, invested at 3 per cent. interest, on	57,750 =	5,037
Expenses working 69 motor cars running 18 hours per day, at 7½ minutes' interval, and nine hours on Sundays, equal 2,429,084 motor car miles, at 5·4d.		54,654
Electric overhead system total annual cost		£90,072

Summing up these estimates, and referring to my previous statement that the relation between the capital and annual cost was not uniform, the fact is here borne out as follows—viz.:

	Estimated capital account.	Estimated annual cost.
Present system	£265,884	£117,222
Electric ,,	378,499	90,072
Cable ,,	428,922	101,819

The difference in favour of the electric overhead system over the cable system is therefore £50,423 on capital account, and £11,747 in annual cost. As the number of cars and service in each of the systems would be alike, the income on each of the systems would be exactly the same; therefore no reference to that side of the account need be here made. So much for the comparison of the available systems financially. Comparing the systems in other respects, I take it without saying that the cable system, costing less than the present system, must be preferred to that system. But what about the electric overhead? Has the cable advantages over it, and, if so, are they so great as will warrant the cable's extra cost?

The advantages of the cable system over the electric are: No unsightly poles, overhead cross wires, or trolley wire along the whole length of each track. No sparking at trolley or car wheels to frighten horses. Less wear of metals, the road being less, and a rolling load, as compared with the grinding load of the electric car. More silent on the road, no buzzing of motors or rattle of gearing. No danger from falling overhead wires. A very large number of extra cars can be put upon a route to meet an emergency at a very slight increase of cost.

The advantages of electric over cable are: no central slot to catch horses' shoes or bicycle wheels, and only two rails instead of three for wheels to skid against. All power generated at the electric station is utilised, whereas by cable three-fourths of the total power generated is used in hauling the cable, however few the number of cars running may be. Electric cars may be run at varying speeds, and so make up for any loss of time, but not so the cable. The cable mode of construction involves repairs and interference with the traffic of the streets, which is not the case in electric. Electric cars can accommodate themselves to street traffic, whilst cable cars cannot, as their speed is regulated by the cable, and they cannot move backwards. A broken or blocked cable stops the whole route, both up and down, and the cars have to be hauled by some supplementary power off the streets, and the cable service on the route, up and down, is suspended until repaired, which must be a considerable length of time, whereas a breakage in the electric wire is purely local; and as the motor cars can move either backwards or forwards, the service can be continued by using the opposite track for both traffics or changing cars at the point of fracture. Less likelihood of traffic being stopped for renewing of wire leads than of cables; no new wires have yet had to be fixed in Roundhay-road, though they have been up three years, whereas cables have to be renewed every year, though by careful daily examination this is often done in the night. Brake power failing on a decline, control is maintained over the electric car by reversing the motor; cable cars cannot reverse, but must go with cable or run away. Cars lit by electricity are far more comfortable and convenient for passengers. In case of being superseded by another system, the materials and work totally lost would be much less in the electric system compared with the cable system. The electric overhead system has a greater field of improvement open to it in regard to cost than the cable system has.

Whilst it is true that the cable cars at a certain frequency of service beat the electric overhead in point of cost, excepting in towns having more severe gradients and a longer length of them than there are in Leeds, this feature has been greatly exaggerated. I find that the frequency required must be less than 1⅓ minutes' service, but it should be remembered, to be complete in this respect, that service must extend over the whole tramway system, or the cable system of the city fails. Such a service, of course, is out of the question. For instance, supposing Briggate and North-street, Boar-lane, Wellington-street, and Woodhouse-lane to Hyde Park Corner were on such a service as would give the advantage to the cable, say, a one minutes' service, the cable system for the whole undertaking of Leeds would then have only 6½ miles of paying line to meet the losses on 28½ miles in the remaining—*i.e.*, the slower part of the system.

It has been suggested to me—and until going into the figures I thought such an arrangement might be feasible—that the centre of the city should be worked by cable system and the outskirts by electricity, but from the figures I have already given it will be seen that the cable system, with its necessarily quick service, and the traffic needful to warrant such service, would be so limited in length as to render such a suggestion not practicable.

Comparing the advantages of the two systems, even ignoring finance, it appears, putting it broadly, that if it were not for the objectionable appearance which the poles and wires of the electric overhead system lends to the streets, and the weight of the car, that system would be practically, in all respects, superior to the cable. In regard to the weight of the car, it is only 6½ tons, and not 9½ tons, as is generally stated, and the weight of those now being made is only five tons, whilst the weight of the present bogie cars drawn by steam-engines is 4½ tons, thus leaving little to be complained of in this respect. As to the poles and wires, a great improvement can be made in regard to them also. All the wires running along the footpath should be laid underground, and all the poles placed against the buildings, or, when the width of the streets will permit, ornamental posts, carrying arc lights, should be placed in their stead in the centre of the roadway. With these improvements, and remembering that electric traction has a wider field for improvement than cable, I am of opinion that the electric overhead system of tramway haulage is certainly to-day, and more certainly for the future, the cheapest and best system for the city of Leeds.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Paris.—The Direction Générale des Postes et Télégraphes, rue de Grenelle, 103, Paris, invites tenders by July 6 for the supply of electric cables in two lots.

Manchester.—The directors of the Manchester Ship Canal Company invite tenders by July 10 for the permanent electric lighting of the Manchester and Salford Docks. All particulars will be found in our advertisement columns.

Portsmouth.—The Corporation of Portsmouth invite tenders by July 10 for conduits and indiarubber-covered electric mains and for "compound" covered electric mains. Further particulars are given in an advertisement in another column.

Bristol.—The Committee of Visitors of the Bristol Lunatic Asylum, Fishponds, invite tenders by July 15 for supply and fixing the necessary wires, lamps, etc., for lighting the asylum by electricity. Further particulars are given in our advertisement columns.

Clevedon (Somerset).—Tenders are invited for the public lighting of their district every night in the year from sunset till midnight, for the Urban District Council. Tenders to be for one, two, or three years, and to be sent to Mr. Hy. C. Fry, clerk, Clevedon, by July 1.

Motherwell (Scotland).—Tenders are invited by the District Committee of the Lanark County Council for the electric lighting of the new hospital being erected near Motherwell. Copy specifications and plans may be seen at the office of Mr. Alexander Cullen, architect, Motherwell. Sealed tenders, marked "Tender for Electric Light," to be lodged with Mr. J. F. Mackenzie, district clerk, County Buildings, Hamilton, by July 1.

Blackburn.—The Corporation of Blackburn invite tenders for the wiring of the town hall. Copies of the specification may be obtained from the engineer, Mr. E. M. Lacey, of 19, Old Queen-street, S.W., on payment of £1. 1s., which will be refunded on return of same accompanied by a bona fide tender. Plans may be seen at the office of the town clerk, or the engineer, from whom any further information can be obtained. Tenders must be sent in by July 13.

Preston.—Tenders are invited for the wiring and fittings required for the lighting by electricity of the Town Hall and public hall buildings. Specifications and conditions at the borough engineer's office, Town Hall, Preston, on payment of a deposit of £1, which will be returned on receipt of a bona fide tender. Separate sealed tenders for each of the buildings must be sent to Mr. Henry Hamer, town clerk, Town Hall, Preston, endorsed "Tenders for Electric Lighting," by 12 noon on July 1.

Dewsbury.—Tenders are invited for the wiring of their premises, for the Committee of the Dewsbury Pioneers' Industrial Co-operative Society, Limited. Copies of the specification may be obtained from the borough electrical engineer, Mr. J. B. Mitchell, Electricity Offices, Bradford-road, on payment of 10s. 6d., which will be refunded on return of same, accompanied by a bona fide tender. Plans may be seen at the office of the borough electrical engineer Bradford-road, from whom any further information can be obtained. Sealed tenders, endorsed "Electric Lighting," must be sent to Mr. J. B. Mitchell, borough electrical engineer, Electricity Offices Bradford-road, by July 8.

Bradford.—Tenders are invited for the supply of best gas coal, cobbles, nuts, and cannel, all to be well screened, dressed, and free from shale and pyrites, to be delivered at the several works of the Corporation in the borough during one year or two years, commencing August 1, for the Gas and Electricity Supply Committee. Form of tender, with any further information required, may be had on application to Mr. Wood, gas engineer, Town Hall. Sealed tenders, endorsed "Tender for Coal," to be sent to Mr. W. T. McGowen, town clerk, Town Hall, Bradford, by July 3. An assurance must be given by each contractor that he pays to the workmen employed by him not less than the minimum standard rate of wages.

St. Helens.—The Electric Lighting Committee of the Corporation are prepared to receive tenders for the supply and erection of the following plant: Section A—boiler-house plant, including

Digitized by Google

boilers and fittings, forced-draught apparatus, feed pumps, etc.; Section B—engine-house plant, including steam alternators, oil-filter, fittings, etc., steam, exhaust, feed, blow-off, and sundry pipes, valves, and water-tanks, etc.; Section C—main switch-board and instruments; Section D—underground work, including cables, junction-boxes, culverts, and trenching; Section E—transformers and fittings; Section F—meters; Section G—overhead crane. Tenderers are at liberty to tender for any section or sections, or for the whole of the sections, but not for part of a section. The ground plan of plant, plan of streets, etc., and specification, with terms and conditions of tender and contract, may be obtained at the offices of Mr. Robert Hammond, the consulting engineer to the Corporation, Ormond House, Great Trinity-lane, London, E.C., on and after June 11, on payment of £2 2s., which sum will be returned on receipt of a bona fide tender. Tenders, sealed, and marked "Tender for Electric Lighting," must be addressed to the town clerk at the Town Hall, St. Helens, and be delivered on or before Tuesday, July 2.

RESULTS OF TENDERS.

Cardiff.—The Corporation have accepted the tender of the British Coal Company for the supply of coal to their electric lighting station at the price of 8s. per ton.

Manchester.—The following tenders have been accepted by the City Council: for the supply of five Lancashire boilers, Messrs. Heaton and Son, £5,371; for the supply of eight dynamo-electric machines, Electric Lighting Construction Company, £7,381; for supply of eight pairs of condensing engines, Mr. B. Goodfellow, £12,440.

Chester.—The following tenders have been received by the City Council for the supply of the electric light:

Alternating current.

Fowler and Co.	£14,893
Siemens and Co.	14,800
Manchester Edison-Swan Company	12,446
Electric Construction Company	11,755
Brush Company (street lighting not included)	8,922

Continuous current.

Electric Construction Company	£14,847
T. Parker, Limited (accepted)	14,200

Cardiff.—Tenders for the electric lighting of Messrs. Hancock's Brewery in Penarth-road have been received as follows:

Fergus and Co., Cardiff	£1,245	0	0
Clay Bros. and Co. (accepted)	1,337	17	0
Strode and Co., London	1,387	0	0
Saunders and Co., Cardiff	1,420	0	0
Knapman, Hodder and Co., Cardiff	1,420	6	0
Lewis and Fletcher, Cardiff	1,477	0	0
Laing, Wharton, and Down	1,572	10	0
Wilson, Aberdare	1,578	19	0
Easton and Anderson	1,579	15	0
Barclay, London	1,640	0	0
Clarke, Chapman, and Co.	1,705	0	0

BUSINESS NOTES.

Western and Brazilian Telegraph Company.—For the past week the receipts were £2,436.

Keyham.—At Keyham Dockyard the local officials have received authority to obtain a steam dynamo at a cost of £700.

Folkestone.—At the last meeting of the Town Council it was arranged to discuss the subject of the electric light at a special meeting.

Derry.—The engineer to the Corporation has been instructed to prepare an estimate of the cost of the proposed electric lighting of the city.

Sleaford.—A suggestion has been made that the water power of the River Slea might be used in connection with an electric lighting scheme for Sleaford.

Mile End.—The Board of Guardians have held a meeting, at which a report on the proposal to light the workhouse by electricity was referred back to the committee.

Cardiff.—Messrs. Clay Bros. are just completing the wiring of the new buildings of the *Western Mail*, where there are nearly 500 lights to be supplied from the town mains.

Bray.—A suggestion from Mr. Fraser, C.E., with reference to the construction of an electric tramway from the railway station at Bray to the summit of the hill has been favourably received.

Burnley.—Mr. Bird Clerke has held a Local Government Board enquiry into the application of the Corporation to borrow £3,000 for extending the electric lighting plant and £2,500 for new mains.

Bell Push.—We have received from Messrs. George Wingrove and Son, 60, Queen Victoria-street, E.C., a circular of Dale's "bayonet joint" electric bell push. They are making it in four patterns.

City of London Electric Lighting Company, Limited.—The transfer books of the 5 per cent. debenture stock will be closed till the 30th inst. for the purpose of preparing the interest warrants.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 23rd inst. amounted to £1,245, as compared with £820 in the corresponding week of last year, being an increase of £425.

Hanover-square, W.—A new public library has been built by the St. George's, Hanover-square, Vestry in Chapel-place North, South Audley-street. It is lighted throughout by electricity.

Glasgow.—It is stated that the North British Railway Company contemplate abandoning the electric lighting system at present used on the Glasgow underground railway. The system in use is known as the fixed rail.

Exhall.—The Parish Council have received a letter from the General Traction Company, Limited, asking permission to use the material of the Westinghouse Electrical Company. It was agreed that permission be given.

Beaman and Deas Syndicate, Limited.—This Company has been registered, with a capital of £30,000, to acquire from J. Beaman and James Deas, of Warrington, Lancashire, certain patents relating to improvements in destructor furnaces.

Barnet.—On the motion of Mr. James, the Urban District Council have resolved to apply forthwith to the Board of Trade for an extension of the electric lighting provisional order obtained in 1893. The application, the mover said, would not incur any expense.

Kingstown.—The Town Commissioners have decided to approve of the application of the Electricity Supply Corporation of Ireland, Limited, to the Board of Trade for a provisional order to supply electricity within the township for public and private purposes.

Change of Address.—Owing to expiration of lease, Mr. J. C. R. Okes, engineer, of 39, Queen Victoria-street, is removing from that address to larger and more convenient offices and stores at Ormond House, 63, Queen Victoria-street, E.C., where his business is now being conducted.

City and South London Railway.—The returns for the week ended June 23 were £794, compared with £863 for the corresponding period of 1894, being a decrease of £69. The total receipts for the current period of the present half-year are £23,093 against £22,618 in the corresponding period of 1894, an increase of £475.

New Agency.—Messrs. Francis and Spilsbury, electrical suppliers and agents, of Mansion House-chambers, 20, Bucklersbury, London, E.C., have been appointed sole agents for the sale of Messrs. J. H. Tucker and Co.'s crank switches in Ireland, and the East, South, and West of England. Mr. Baker (Messrs. J. H. Tucker and Co.'s present London representative) still retains his agency for London only.

County of London and Brush Provincial Electric Lighting Company, Limited.—The directors have declared an interim dividend for the half-year on the preference shares at the rate of 6 per cent. per annum calculated from the due date of payment on the £2 per share paid up, and payable to all registered shareholders on the books of the Company at June 30, 1895. The transfer books will be closed from July 1 to July 14 inclusive.

Aberystwith.—A meeting of the Town Council has been held, at which a communication was read from Mr. Aslett, secretary of the Cambrian Railways Company, expressing the disappointment of his directors that no electric lamp had been placed by the railway station. The matter was referred to the Public Lights Committee. On the motion of Alderman C. M. Williams, it was decided to refer Mr. Preece's report on the electric light to the Public Lights Committee.

Liverpool.—Petitions have been deposited in the Private Bill Office of the House of Lords by the Liverpool Electric Supply Company, Limited, and by the Corporation of Liverpool, for leave to introduce a Bill this session to authorise the transfer of the undertaking of the company to the Corporation. The petition came before the Examiner of Private Bills in the House of Lords on Tuesday. It was decided to report that the petition had failed to comply with the Standing Orders.

Eastern Extension Telegraph Company.—The directors have declared an interim dividend for the quarter ended March 31 last of 2s. 6d. per share, free of income tax, payable on July 15. The share register will be closed from July 6 to July 13, both days inclusive. The coupon on the company's 5 per cent. Australian Government subsidy debentures due July 1 will be paid, on and after that date, at Messrs. Barclay, Bevan, and Co.'s Bank, 54, Lombard-street, London, E.C. Coupons must be left three clear days for examination.

London, W.C.—We understand that Messrs. Vaughan and Brown, Limited, have just completed the installation of Romano's, in the Strand, which since its rebuilding is one of the handsomest restaurants in London. In addition to the electric lighting, they have executed the whole of the ventilation by means of electric fans, together with the gas lighting electric bells, despatch and speaking tubes, under the direction of Mr. W. Emden, architect. The above firm have also just completed a large installation of about 1,200 lights at the North-Western Fever Hospital, Hampstead, under the direction of Prof. Ayrton, also the whole of the electric bells, telephones, speaking-tubes, and gas lighting throughout the building.

Bath.—The electric light company's employés had an outing last week, and were accompanied by Mr. G. F. Metzger (engineer and manager) and Mr. W. Jeffery (secretary). A start was made in brakes about eight o'clock, the drive *vid* Farmborough, Marksbury, and Chewton, where horses were changed, being very enjoyable. A luncheon was served at the Cliff Hotel, and during the afternoon the party viewed the caves. Tea was partaken of at five o'clock, and before dispersing Mr. C. Cornelius proposed a vote of thanks to Mr. Metzger, which was supported by Mr. Jeffery. Mr. Metzger responded, and was heartily cheered. On

Digitized by Google

the return journey a halt was made at Chewton, where dancing was indulged in, and songs were rendered by some of the company. Bath was reached about 11 o'clock.

Bristol.—The Sanitary Committee have held a meeting, at which a letter was read from Mr. W. A. Todd, who was unavoidably absent, asking the committee to consent to a proposal of the tramways company which, whilst giving two extra electric lamps in Old Market-street, would reduce the number of standards from 15 to 10, and the additional cost to the city would be only £25. The Vice-Chairman said he thought Mr. Todd had been misinformed. The cost would be £25 per annum per lamp. After a debate on the extra two lamps for Old Market-street, the question was ultimately referred to the Electrical Committee, several members protesting against the extra cost, stating that if extra lamps were to be provided anywhere, Bristol Bridge and other thoroughfares named should be favoured.

Appointments Vacant.—The governors of the Northern Polytechnic require applications for the appointment of principal. After March 25, 1896, the stipend will be at the rate of £500 per annum, and the principal will be required to devote his whole time to the work of the institute. From September 29, 1895, till March 25, 1896, the stipend will be at the rate of £300 per annum, and the principal will be required to attend the governors' meetings, to take supervision of the equipment of the institute, and to make arrangements for the future educational work. Applications must be made on or before July 15 on forms which, together with particulars of the duties of the office, can be obtained of Mr. E. Griffiths secretary, St. Mary's Vestry Hall, Islington, N.—The House-to-House Electric Lighting Company, Earl's Court, want a fitter.

Croydon.—Major-General C. Phipps Carey, R.E., has held an enquiry on behalf of the Local Government Board, at the Municipal Offices, Park-street, into the application of the County Council for sanction to borrow £27,000 for electric lighting purposes. The town clerk (Mr. C. M. Elborough) appeared for the Corporation. Mr. Alderman Miller, J.P., the chairman of the Electric Lighting Sub-Committee, stated that he was of opinion, from personal enquiries, that the electric light was much desired in the borough. The Corporation were erecting a new town hall and other public buildings and would be large consumers of the light. The Inspector said he thought the Local Government Board would require more details, and pointed out that no plans had been put in with regard to the proposed buildings. The Town Clerk said Prof. Kennedy would undertake to supply the plans in a fortnight, and the enquiry closed, the inspector promising to report in due course.

Fort William.—A meeting of gentlemen interested in the promotion of an electric light scheme for the burgh of Fort William and district has been held in the Town Hall there. Mr. Yorke, electrical engineer, was present, and explained the proposed method of working. The matter has been very heartily taken up, and a company is now being formed to carry out the scheme. Mrs. Cameron Campbell, the proprietress of the ground on the west side of the River Nevis, from which stream the motive power is to be obtained, is to give the land through which the water is taken, and the use of the water itself free. Negotiations are proceeding with Lord Abinger, on whose ground the turbine-house will be erected, who is also interested in the water, and it is hoped similar favourable terms will be arranged with him. It may be mentioned that the late Lord Abinger supported a similar electrical scheme, and it is anticipated that the present Lord Abinger will also be favourable to the project.

Private Bill Legislation.—Before Lord Camperdown's Committee, the Strand electric lighting order raised a controversy between the Charing Cross and Strand Electric Company, who are the promoters of the order, and the Metropolitan Electric Supply Company. The former company represent the principle of the direct continuous current, and the latter the alternating high-tension system. Mr. W. T. Madge, of the *Globe* and the *People*, spoke highly of the former system for driving the Linotype composing machines, and Mr. Vesey, consulting electrical engineer to the *Graphic*, *Daily Graphic*, *Illustrated London News*, *Tit Bits*, and other papers, also expressed his preference for the direct continuous system for newspaper machinery. The committee adjourned, and on Tuesday the committee heard further evidence as to the relative merits of the methods employed by the Charing Cross and Metropolitan Electric Companies, the latter being supported by Lord Kelvin and Mr. Ferranti. The committee passed the order giving powers to the Charing Cross Company.

Manchester Suburban Electric Supply, Limited. — The prospectus of this undertaking has been issued. The subscription lists will close on Saturday, the 29th inst. The share capital is £25,000, divided into 3,000 6 per cent. preference shares of £1 each, and 22,000 ordinary shares of £1 each, half of which are now offered for subscription. The directors comprise Mr. Charles Hunter (chairman), Mr. James Nuttall, Mr. Joseph Nasmith, Mr. Thomas Parker, and Mr. E. Jessie Piper. The offices are at 8, South King-street, Manchester. The district proposed to be dealt with in the first instance is that of Moss Side, and favourable arrangements have been made for the acquisition of a plot of land for the erection of a generating station. The directors in the first instance propose to put down a plant and mains sufficient to light the district, including Whalley Range, and Moss-lane East and West, from the District Council offices to the Whalley Hotel, and along the Alexandra-road to Yarburgh-street, but as the demand for current increases in the rest of the district it is proposed to lay down mains in the whole area covered by the order. Already applications have been made for current sufficient for 2,250 lamps, and the forward prospects are decidedly good. The promoters state that from "the returns of other companies it is safe to estimate that the revenue from these applications should be at least £1,000 per annum, and the working expenses for the first year should not exceed £600, so that there is every probability of the undertaking being supported and paying its way the first year, while all increase of custom will add to the profits of the company.'

Electric Organ Company, Limited.—The Electric Organ Company, Limited (Hope-Jones system), has been formed, with a capital of £110,000, divided into 55,000 £6 per cent. cumulative preference and 55,000 ordinary £1 shares, for the purpose of acquiring and carrying on upon an extended sale the business of the Hope-Jones Electric Organ Company, Limited, and to take over the patents, plant, and other property now held by that concern, and certain further patent rights more recently applied for by Mr. Hope Jones relating to improvements in organs and new methods of producing organ tone. It is also proposed to secure the Hope-Jones electric organ patents for France, Belgium, Germany, Austria, and Hungary, including the benefit of a license granted to Messrs. François Mader et Cie. for certain rights in the French patents for which they agree to pay a royalty, and the right to all further improvements in organs and organ building which Mr. Hope-Jones may invent during his engagement with the Company, including the right to adapt his inventions to harmoniums, American organs, etc. The Hope-Jones Company was formed in 1892 with a capital sufficient to test and introduce Mr. Hope-Jones's improvements in the application of electricity to organs. The purchase price has been fixed at £29,348, of which the vendors have agreed to take £17,340 in the form of a deferred interest in the future profits, by the issue to them of ordinary shares as fully paid up, and £12,008 in cash. The public were invited to subscribe for the whole of the preference and for 37,660 ordinary shares, the list closing at the beginning of this week.

York.—The City Council on Tuesday night further considered a report of the Electric Lighting Committee recommending the acceptance of the tender of the Electric Construction Company, of Wolverhampton, to supply the necessary plant and fittings for the sum of £10,865, and application for sanction to borrow £15,000 for the purpose. The scheme proposed is know as the Oxford system. There were three other tenders as follows: Siemens Bros. and Co, £10,345; Brush Electrical Engineering Company, £8,360; C. A. Parsons and Co., £10,266. Alderman Agar moved, and Mr. Mann seconded, the adoption of the report. Alderman Wragge spoke against the motion on account of the costliness of the scheme, and moved an amendment that the tender of the Brush Company be accepted, with a provision for the working of the plant by them for a term of years, subject to a modification of the terms proposed. The amendment was seconded by Alderman Coning, and after some discussion it was out to the meeting, when the voting was—for the amendment 4, against 10, neutral 12. The amendment was therefore lost. Mr. Purnell spoke at considerable length, comparing the various schemes, and concluded by moving that the tender of C. A. Parsons and Co. be accepted. Mr. Anderson seconded, but the amendment was rejected, only six voting for and 13 against. Further discussion ensued, after which Alderman Coning moved that the report of the Electric Lighting Committee be referred back with instructions to ascertain from the four companies on what terms they will supply the city and work the plant for a term of years. Alderman Wragge seconded, and it was carried, after which the Council adjourned.

Edinburgh.—A meeting of the Town Council has been held, at which it was recommended by the Lord Provost's Committee to extend the high-tension electric light mains to the district of Regent, Carlton, and Royal terraces, to South Back Canongate, to George-square, and to the south side of the city, at a probable cost of about £5,000. It was explained by Councillor Mackenzie that the committee proposed to lay a ring main to the south side by Princes-street, George-square, The Grange, and Morningside, in order to carry the high-tension current, without which those places could not be supplied with the incandescent light. Mr. Cranston asked if the committee had received the necessary guarantee, and Mr. Mackenzie said that from the people in the terraces they had more than the necessary guarantee, and in Clerk-street and George-square they had the same, but they could not give the supply without the high-tension main. The question was, therefore, whether it was desirable to put in this ring main or simply to make some temporary attempt which would subsequently have to be thrown overboard. They considered the electric light was a success, and that the proper thing to do was to put in this ring main at once. Mr. Cranston moved that sanction be delayed until the guarantee was obtained, and Mr. John Jamieson seconded. After some further conversation, however, Mr. Cranston withdrew his motion, and the report of the committee was adopted. Mr. Mackenzie and Sir James Russell were afterwards appointed to attend in London in the matter of the regulations and conditions proposed to be made by the Board of Trade in the interest of public safety in connection with the installation of the electric light.

Central London Railway.—The directors of the Central London Railway Company have announced the issue of 285,000 £10 shares, the subscription list for which was opened on Monday last and closed on Wednesday. The Company was incorporated in 1891, and obtained further powers in 1892 and 1894. The share capital consists of £2,850,000, and the borrowing privileges extend to £950,000. The line is to be about 6½ miles long, and will run between Shepherd's Bush and Liverpool-street, under Uxbridge-road, Bayswater-road, Oxford-street, High Holborn, Holborn Viaduct, Newgate-street, Cheapside, Poultry, and Old Broad-

Digitized by Google

street. The motive power will be electricity. A contract has been entered into with the Electric Traction Company for the acquisition of the necessary land and the construction and equipment of the railway with all its appurtenances for the lump sum of £3,244.000, payable as to £2,544,000 in cash and £700,000 in debenture stock bearing 4 per cent. interest. The contractors undertake all risks and contingencies of every kind in connection with the construction of the line and works, which are to be handed over complete and in working order ready to be opened for public traffic by December 31, 1898. From estimates made by the engineers it appears that the total working expenses with an electric 2½-minute train service may as a maximum be taken at £152,000 a year. Calculating on an average receipt of 2d. per passenger, and the expenses as mentioned, the anticipated annual traffic, taken at 7,000,000 passengers per mile, would, it is stated, yield sufficient net receipts to pay 4 per cent. on the debenture stock and 5 per cent. on the share capital, with a margin of over 1 per cent. on the latter for contingencies.

New Government House, Rangoon.—The whole of the electric light installation for this magnificent new building has been supplied to the order of H.M. India Office by Messrs. Henry F. Joel and Co., of Wilson-street, Finsbury-square, London, under the supervision of Mr. W. H. Preece, F.R.S., and consists of two Joel patent dynamos, each capable of lighting 250 lamps, together with main switchboards and distribution switch and fuse boards, all fitted in polished teak cases and specially constructed to withstand the heat and moisture of the climate. There are nearly 400 lamps fitted, of which 11 are of 200 c.p. The lamp fittings are designed to agree with the beautiful decorative architecture. Full details and carefully-made plans and descriptions were sent by Messrs. Joel and Co. with the materials to facilitate the erection of the plant. The two engines and two boilers were supplied by Messrs. Davey, Paxman, and Co., of Colchester. The engineer in charge at Rangoon officially reported that the quality of the materials was of the highest character. The following is taken from the *Rangoon Times* of May 10, 1895: "A trial of the electric light took place at the new Government House last night, and proved most successful. Lady Fryer, Mr. Hoyne Fox, and Mr. MacDonald (superintending engineer of the I.F. Company) were present, and a few others close by had a peep. The whole house was a mass of light. The two magnificent lamps in the portico were a grand sight. All the other lamps of varying sizes with good opal shades were also very effective. Great credit is due to the I.F. Company for the erection of the lights. There was not a hitch. Mr. King, the engineer, who was in charge of the erection of the wire, lamps, etc., had to undergo a great deal of inconvenience when running the wires, while other works were being carried out."

Interior Conduit System.—We have received from the General Electric Company, Limited, 69, Queen Victoria-street, E.C., a circular descriptive of their "interior conduit" system of electric wiring. This system is one in which a highly insulating, waterproof, and practically fireproof tube or conduit replaces wood casing. It is admitted that wood casings have many disadvantages, amongst which may be enumerated unsightliness, unnecessary cost of labour in erection, etc., and share in common with ordinary metal pipes the want of mechanical and electrical properties which are essential to a safe and durable installation. "Concealed" or "plastered-in" electric wiring work is continually increasing, and it is recognised that the present system of wood casing and other methods must be gradually superseded by some system designed with a more exact knowledge of the conditions to be fulfilled. The firm's system of "insulating tubing" is presented in three grades—plain, brass-covered, and iron armoured—as satisfying all the conditions necessary to the erection of a perfect installation. Prominent among the advantages of this system may be mentioned the fact that the tubing can be installed with a saving of 30 per cent. to 40 per cent. in labour, as compared with wood casing, since all mitreing and screwing on of covers is avoided, all necessary bends, elbows, etc., being provided ready-made. The tubing having once been installed throughout a building, the wires can be drawn in or out whenever required with a minimum of inconvenience and cutting away. It can safely be embedded in plaster, in the same way as speaking-tubes or gas and water pipes, thus admitting the planning of a complete and comprehensive system of conduits in which the wires are always accessible. When using tubing, it will be found most convenient to adhere to the "centre of distribution" method of installation, so that all fuses are grouped together in convenient positions. From these "centres" tubes can be led off to the points in service.

Bangor (Wales).—The question now before the City Council of introducing the electric light into Bangor has created a great deal of interest amongst the inhabitants of the city, says a local paper. It was expected that the report of Mr. Medhurst (the consulting engineer appointed by the Council to aid them in this matter) would be to hand soon, when it would be fully discussed by the Electric Light Committee of the Council. Much hope is entertained that the report will be a favourable one, inasmuch as the setting up of an electric light installation would undoubtedly enhance the value of Bangor both as a place of residence and a resort for visitors during the summer months. Considerable doubt seems to pervade the minds of some of the inhabitants as to the manner in which the electric light and the present gasworks could be carried on together without any detriment to the latter. It is certain that a large sum of money must be spent upon the gasworks immediately, unless something else is done, in order to meet the increasing demand for gas, and also to supply the large number of new houses which are in course of erection at present. Many members of the City Council are of opinion that this is a favourable opportunity for introducing the electric light to Bangor. If the same price is charged for the latter as for gas it cannot make any difference to the Council whether they put more capital into the present gasworks or expend such additional capital upon an electric light installation, provided the same profit can be made out of it. Judging from the experience gained in other towns and the dividends paid by various electric lighting companies, a much larger profit can be made by the supply of electric light than by the supply of gas. Several of the leading householders and tradesmen in Bangor have intimated their intention of taking up the electric light as soon as the necessary plant for its production may be laid down. It is further to be hoped that many householders who now do not use gas in their houses, as well as others, will come forward to assist the Electric Light Committee in carrying out this important proposal for the good of the community by having their houses and business premises wired for the electric light.

Brighton.—At a meeting of the Lighting Committee of the Town Council, held on 10th inst., tenders for the supply of coal to the electricity generating station during the year commencing July 1, 1895, were considered and it was resolved to accept the tender of Messrs. Banfield and Co. to supply Powell Duffryn (Fforchaman) at 19s 7d. per ton and Linby at 17s. 3d. per ton. A letter from Councillor Halliwell as to the lighting of Lewes-road, and suggesting that some of the Sugg lanterns proposed to be removed from the Marine-parade should be placed there, was referred to the borough surveyor to report upon. The letter from the town clerk of Hull, with reference to the regulations and conditions for securing the safety of the public proposed to be issued by the Board of Trade, and enquiring if the committee are prepared to assist in a joint representation being made to the Board, was again submitted. A further letter was submitted from the town clerk of Hull on the subject, and forwarding print of proposed draft regulations showing the clauses which, in the opinion of the Hull Electric Lighting Committee, require modifying, and inviting representatives of the committee to a conference at the Westminster Palace Hotel on the 11th inst. Letters from the manager on the subject of the proposed regulations were also read. It was resolved that the Mayor, the chairman, the town clerk, and the manager of the electricity works be requested to attend the conference. Councillor Stafford, in moving the confirmation of these proceedings at last week's meeting of the Town Council, explained that the committee accepted Messrs. Banfield and Co.'s tender for one class of coal at 17s. 3d., instead of that of Messrs. Rickett Smith, and Co. at 16s. 6d., because the application for tenders was for the two kinds of coal, and they could not divide them. Councillor Greenyer asked if, as they were laying a new cable in Edward-street, that was likely to produce any other business. It was a large amount to spend to supply one man. Councillor Stafford replied that the Lighting Committee never put down cables unless they were assured they would pay. The Lighting Committee submitted tenders they had received for the supply of 45 cast-iron upright posts with bracketed canopies, required for supporting electric light arc lamps. The committee recommended the acceptance of the tender of Messrs. Mackenzie Bros., of Edinburgh, for £1,530. On the motion of Councillor Stafford, this report was adopted.

Portsmouth.—The electric light in Portsmouth has just passed its first anniversary, says a local paper, and no commercial or municipal undertaking could have given more satisfactory results, thanks mainly to the indomitable perseverance of the chairman of the committee, Alderman G. Ellis, J.P. Wherever the mains have been laid tradesmen and residents have eagerly introduced the light into their establishments, and requests have come in from all sides urging the committee to extend. In fact, many tradesmen, while effecting alterations to their establishments, have had them wired, so as to be ready to use the electric light so soon as the cables pass through the street. It is to meet this general demand that extensions are about to be undertaken which will include all the main thoroughfares of the borough within the lighting district. At the present time the mains stop at All Saints' Church. They are now to be extended as far as the tramway stables at North End. Mains will be taken from Kingston Cross through Buckland and Fratton roads, Victoria roads (North and South), Marmion-road, and Kent-road, and joining the existing main at the Pier Hotel corner. From Portsea, the present Queen-street main will be extended up Edinburgh-road, and it will be carried from Commercial-road through Arundel-street and Fratton-street, along Fratton-road, through St. Mary's-road to the lunatic asylum Other mains will be taken up Lake-road and through Fawcett-road and along Albert-road, joining at the Victoria-road police station. Over this area there are to be 250 arc lamps for public lighting. At present there are 100 of these lamps in the borough. The advantage for street-lighting is immense, and although apparently more expensive than gas, yet, light for light, it is not one-tenth the cost. Each arc lamp will be of 12½ amperes power, equal to 2,500 c.p. whereas the ordinary five-light gas burners, with which most of the main roads are now lighted, do not range beyond 100 c.p.—most of them not more than 80. It was stated at the last meeting of the Council that the lunatic asylum was to introduce the light, and now, we understand, all the police stations are also to use it. All this public lighting, with the additional private lighting, will give a big revenue next year. Altogether, Alderman Ellis and his committee are to be congratulated on the first year's working, and on the leading position they have given Portsmouth among the cities and towns of the kingdom that use the electric light.

Stoke-on-Trent.—The Town Council have held a meeting at which a sub committee of the Council who had met the chairman and electrical engineer of the North Staffordshire Tramways Company (Messrs. Carruthers-Wain and Sellon) on the subject of the proposal to work the tramways by electric traction by means of overhead wires, reported that in reply to a question as to whether it would not be possible to lay the wires underground, and so do away with the posts for overhead wires, which would have to be fixed 40 yards apart, Mr. Sellon said it would be absurd to contend that the underground or conduit system could not be adopted in the district, but there were at the same time many disadvantages. In the first place, the rain and damp would sink into the mains, flood the whole of the installation, and thus be the means of suspending the whole of the traffic from time to time; and in the second place, the extra cost per mile would amount to between £2,500 and £3,000, which in itself would make it impossible for the company to carry out the conduit system. The question of the double lines in Church-street was discussed, and Mr. Wain said he should prefer to leave that matter to the Board of Trade, and he would abide by its decision. He did not see, however, how they were to give a more frequent service without the second line to carry the traffic of the London-road section. The question of the extension of the tramways to Trent Vale was considered, and Mr. Wain stated that the company would immediately apply for a provisional order to extend the line to Hanford Bridge as desired, providing the Corporation gave its consent to their proposals. The sub-committee recommended that, subject to the whole of the local authorities in the district being of the same mind, and to satisfactory replies being received to enquiries to be made by the town clerk from places where overhead traction had been adopted, the Corporation should consent to the introduction of electrical traction by means of overhead wires, and subject to the company giving a satisfactory undertaking to apply for a provisional order to extend the present terminus in London-road to Hanford Bridge within a period of two years from the date of the granting of such order. With respect to the undertaking required by the company as to the Corporation not exercising their option of purchase under the provisions of the Tramways Act, 1870, at the end of 21 years, the committee recommended that the matter remain over for further consideration, to enable the Corporation to ascertain what such purchase would include. The report was adopted without discussion.

Cardiff.—A meeting of the Lighting and Electrical Committee of the Cardiff Corporation has been held under the presidency of the Mayor (Alderman Carey). A letter was read from Mr. J. Ballinger, chief librarian, directing the attention of the committee to the fact that a reduction or discount on the cost of supplying electric light to the free library had been promised to that institution. The letter pointed out that on the faith of that understanding the Free Library Committee had made arrangements for the electric lighting. A former letter to the same effect had been written by Mr. Ballinger, but to that communication the committee had replied that, seeing that all other departments of the Corporation were charged the full terms for electric lighting and no reduction had been allowed, the committee could not see its way to allow any discount to the free library. It was seen by reference to the minutes of the Lighting Committee of September 18, 1894, that an agreement was made therein for a substantial reduction being granted to the free library if a large quantity of electricity were consumed. It was agreed that the Library Committee be informed that this resolution would be adhered to, but the amount of the discount could not be estimated until the quantity of electricity consumed had been ascertained. A motion was made by the Mayor that for the benefit of those townspeople who were patrons of the Channel trips a Bray lamp be erected at the pier head, near the Windsor Hotel. The whole neighbourhood was at present only illuminated by one lamp. The borough engineer was instructed to report upon the matter. A long discussion took place as to how it came about that a pair of small engines at the Canton lighting station were not in use It was explained by Mr. Massey that the committee had altered its plans, and that the engines were required to do work that they had not been designed to perform. It was his opinion that the committee would never get the full amount of lighting until they ran the engines the whole 24 hours. It was also contended that the number of hands employed at the works—17—was very large, and that an unnecessarily large number of fitters were engaged. A letter to the Press from Mr. S F. Walker alleged that the pipes under the streets containing the service cables were, when recent excavations were made for gas and water mains, found to be seriously corroded in certain places. The Mayor regarded this as a very serious statement, and thought the committee ought to investigate it. It was arranged that Mr. Walker should be asked to indicate to the borough engineer the exact spot where the corrosion complained of was to be found. Mr. Good entered into a general criticism of the works in regard to both construction and management, and pronounced both most unsatisfactory. The *Western Mail* has interviewed Mr. Harpur, the borough engineer, who stated that satisfactory progress was being made with electric lighting in Cardiff. New premises were continually being wired, and fresh applications were almost daily received. There were now upwards of 60 consumers, and in several cases premises had already been wired where there were no Corporation mains, and in anticipation of the extensions proposed in Newport-road, as far as Castle-road, West-grove, up to the south end of Richmond-road and down Charles-street and Nelson terrace to the new baths, which are also to be lit by electricity. An application has been made to the Local Government Board for loans to the amount of £5,385 to carry out the extensions indicated.

Fulham.—The Vestry have held a meeting, at which Mr. Sayer had a motion on the agenda paper to take precedence of all other business, but as the member was not in attendance it was suggested that the matter should be withdrawn. Mr. Marks said it was usual for the Vestry to show courtesy to a member who was unable to attend the Vestry at the appointed time. He did not know why this courtesy should not be shown to Mr. Sayer. The Chairman explained that it was arranged to take the motion which had reference to the introduction of electric lighting in the parish at the commencement of the business. Mr. Lacey condemned the suggested scheme as the rates were already high enough, and the finances of the parish did not justify the Vestry in embarking on a heavy expenditure. He therefore moved that before instructing any electrical engineers to report upon the question of introducing the electric light into the parish, the parishioners be polled in a similar manner to that adopted in the case of the free public library. Mr. Perry seconded the proposition. The Chairman pointed out that they were altogether in the dark as to whether such a scheme could be worked with profit to the parish. He suggested that they should first consult an electrical engineer on the subject, and then the Vestry would be in a position to decide one way or the other. Mr. Marks concurred with the chairman, and said the proposed expenditure of £50 for expert evidence would be money well spent. They desired information on the subject, and if the Vestry now ran away from the idea they would be the laughing-stock of London. He ridiculed members running away from their previous opinions. The suggestion would only bind the Vestry to the preliminary expenses. Mr. O'Brien also thought that the expenditure of £50 would be money well spent. Mr. Green urged the Vestry to hesitate, because it would be a serious matter if after the introduction of electric lighting into the parish they found that it could not be supported. Mr. Lacey withdrew his motion, as the general opinion of the Vestry was in favour of obtaining expert information from an electrical engineer at a cost of £50. Mr. Thelwall then moved that the matter be referred back to the Electric Lighting Committee, with instructions to report as to the following points: (1) whether they consider that there is reasonable ground for supposing that electric lighting, in conjunction with a dust destructor, can be installed in the parish at a profit to the ratepayers, and without involving any addition to the rates; (2) in the event of the committee returning an affirmative answer, to state their reasons for the conclusion at which they have arrived, and select the names of three engineers or firms of engineers, of whom they recommend the Vestry to choose one, with a view to his being asked to report as to whether the suggested installation can be carried out in such a manner as to prove a source of profit to the parish. Mr. Marks said the last speaker forgot to mention that it was proposed to provide a dust destructor so that the two things could be worked together at a considerable saving to the rates. Mr. Thelwall's motion was carried, with the addition that the committee be empowered to spend £50 in obtaining the required information.

Southampton.—The Works Committee have reported to the Town Council that the sub-committee appointed to consider the question of the Board supplying their own electric power had again considered the report from Mr. Aldridge as to the proposed electric plant at the Town Quay. Mr. Aldridge therein adhered to his statement of cost of production (estimated at 3·90d. per unit), and also as to the capital outlay, with the exceptions as to the buildings and site. He discussed with the committee the suitability of several sites, and suggested the Board's yard as the most desirable. In conjunction with the surveyor, he estimated the cost of the proposed buildings at £1,200. The sub-committee unanimously resolved that, having carefully considered the reports from the electrical engineer showing that a current might be obtained at about 4d. per unit, as against 6d. now charged by the company, it appeared desirable that the Board should have an installation of their own, but before deciding definitely what should be done they thought it would be well to await the decision of the Corporation as to the purchase of the works of the company, in the event of which satisfactory terms might be arranged with the Corporation. The committee adopted the report of the sub-committee. Before the minutes were read, Mr. Emanuel objected to the chairman—as he was interested in the electric lighting company—presiding over the Board whilst the Works Committee's minutes affecting the electric lighting of the pier and harbour were under discussion, and moved a resolution to that effect. Alderman Cleveland thought it necessary that they should have the information the chairman could impart, and on the point of legality being raised, the clerk read the by-law affecting the matter. This showed that any interested commissioner could be present during proceedings, but was not competent to vote. Mr. Emanuel: I object to your presiding, Mr. Chairman. The chairman insisted that he was not disqualified from presiding, and took upon himself the responsibility of the course he adopted. Mr. Hogge seconded Mr. Emanuel's motion. Mr. Emanuel added that every gentleman, directly or indirectly interested, should take the course he had suggested, and take no part in the deliberations of the Board on the question of electric lighting. Alderman Cleveland did not think Mr. Emanuel should press his objection, as it seemed by the clause that the chairman was perfectly entitled to sit. Five voted against the proposition and three in favour of it, the remainder either being neutral or abstaining from voting. The chairman accordingly declared the motion lost. The minutes having been read, Mr. Gayton moved their reception. In doing so, he said he was placed in an invidious position by the absence of Alderman Bone. Mr. Scovell seconded. Mr. Emanuel said the matter had been a long time under discussion, and urged the necessity on the grounds of economy of the Board providing their own electric light. He pointed out that the supply at the free

Digitized by Google

library had been very cheap and satisfactory, costing, as it did, 3¼d. per unit, including lamp renewals, etc., whilst the Board was paying 6d. per unit. He did not think they ought to wait for the Corporation. Even if that body did acquire the electric lighting works, they would have quite sufficient to do to supply the town. He had gathered that the amount paid for electric light in the months of March and April was £88. 7s. 6d., equal to £530 a year. He moved, as an amendment, that the Works Committee be instructed to at once take steps to provide their own electric light. Alderman Cleveland thought that with the possibility of a good customer like the Harbour Board the electric light company might get a better price for their undertaking from the Corporation. He did not see why the ratepayers should be called upon to pay more than they were actually worth. The amendment was put to the vote and carried by 13 votes to 1. The Chairman, after declaring the vote, said it might satisfy Mr. Emanuel when he told him that he was one of the first to propose that the Harbour Board should supply their own electric light. Mr. Emanuel said it was the principle of the thing he objected to The sub-committee of the Works Committee reported that, having considered the report of the wharfinger as to the supply of crane power at the quay extension, they recommended the Board to obtain estimates for three additional cranes—viz., one 12-tons and two 2 tons. The committee's recommendation was approved.

Bristol.—At a meeting of the Assessment Committee held at St. Peter's Hospital for the purpose of hearing appeals, the case of the rating of the city electrical station and general lighting service was taken. The assessment returned stood at £3,000 gross and £1,850 ratable value, otherwise net. Mr. Wise (from the town clerk's office) showed cause against the figures, and Mr. Parr (Osborne, Ward, Vassall, Parr, and Co.) supported the rating authority. Mr. Wise, who was heard first, said he should ask the committee to reduce the estimate for rating purposes to £1,745 gross and £1,428 net. He remarked that the account on which his figures were based showed that the number of private lamps fixed on December 31 was 15,000. He had estimated for an increase of about 2,300 for the present year, and the account he was presenting was therefore based upon the number of lamps being 17,425. They got an average revenue of 6s. 11½d. per lamp, which in the total he had given, would yield £6,062. 9s. 2d. Certain customers were allowed discounts varying, according to the amount of their bill, from 5 to 20 per cent., which worked out to an average reduction of 3 per cent., equal to £181. 7s. 5d., bringing the net revenue of private lamps down to £5,880. 11s. 7d. The next source of income to be dealt with was the quantity of electricity supplied to street lamps. This came to 150,417 units; the number of public lamps was 90, and these were charged at the same price as private consumers—namely, 6d., which equalled £3,760. 8s. 6d. The lighting authority was clearly entitled to be treated on the largest consumer basis, and so came in for 20 per cent. reduction, amounting in all to £752, which left the net revenue from street lamps at £3,008 and the gross from all sources £8,888. Next, they were confronted with the cost of production, which totalled up to £5,808, and subtracting this from the gross they had again the net at £3 008. Deducting therefrom tenants' share of revenue and landlords' deductions, the total was still further reduced to £2,061, from which had to come rates and taxes at 6s. 8d. in the pound, amounting to £516, which brought down the net annual value of the whole undertaking to £1,545. Inasmuch as the works were situated in two poor-law unions, with a gross of £676 outside that authority, this brought it down to £1,428, to which sum he asked the committee to reduce the assessment. Enquiries had been made in various quarters to ascertain the amount at which electric light stations were assessed, and in no case except Manchester did it approach to anything like the sum which was put down on the Bristol undertaking. In Manchester, where it was assessed at £2,500, there was a supply of 439,000 units as against Bristol's 293,000. The Board of Trade returns markedly corroborating what he had advanced, his committee thought that they were being unfairly dealt with and the sum which he had asked the authority to fix for the rating was a fair and reasonable one. Mr. Parr enquired the cost of the whole of the undertaking in Bristol, remarking that unless they knew that the comparisons with other towns might well be fallacious. Mr. Wise said that the entire cost, including meters, was £82,000. At present the undertaking was not paying. Mr. Parr: That is so; but as a matter of fact you have a rate in aid—how much does this amount to? Mr. Wise: For the year 1894 the rate in aid was £7,000, which included the public lamps, from which we get no revenue at all. We pay £300 rent for the main building, which is the same that the previous occupier paid. Mr. Parr contended that it was a fallacy that the public lamps were to be charged for at the same rate as private lamps. Looking at the whole cost of the undertaking at £82,000, he was going to submit that the amount of rating arrived at was a very moderate one indeed. What they had to find out was what would the undertaking let at from year to year. It was worth a great deal more than Mr. Wise had stated it would be in private hands, because there was to be added the £7,000 rate in aid. He asked the committee to discard the whole of the figures as far as the 90 lamps were concerned. Mr. Wise, replying to questions, distinctly assured the committee that up to the present no profit had been made either on the public or private supply. Mr. Parr said the position was simplicity itself; to the £3,760 they should add the £7,000. The first named was the estimated lamp revenue, and the £7,000 was the rate in aid. If this were done it would be seen that the rating was too moderate—that, in fact, it ought to be increased. Mr. Wise contended at length that the Erith case and the Merthyr Tydfil case established to the full the line he had taken. Mr. Parr still urged that there was no justification for the allowance of 20 per cent. in respect of the public lamps. The Chairman (Mr. R. C. Stephens) said the committee quite recognised that it was an appeal between two public bodies, and it would be their desire to establish a fair, impartial rate. The room was then cleared, and on the reassembling, the Chairman said they had gone into the figures very carefully, and had paid full attention to what had been urged. The committee would leave it to the parties to arrange the gross value, but they had fixed the ratable value at £1,500. The proceedings then terminated.

Light Railways.—The Public Health and Housing Commitee of the London County Council on Tuesday reported as follows: It will be remembered that the Council having been invited to send representatives to a conference convened by the Board of Trade on the subject of light railways, appointed Mr. Fleming Williams, Mr. Bruce, and Mr. Beachcroft to attend the conference. The conference having resulted in a Bill now before Parliament, a report on the subject is called for. The conference referred to at its first meeting in December last appointed a representative committee to consider "(1) how far the usual requirements of the Board of Trade as to constructing and working new railways may fairly be relaxed, especially in the case of lines built through sparsely-populated and agricultural districts, and (2) whether additional legal facilities for obtaining powers to construct tramroads and light railways are necessary or desirable" The President of the Board of Trade, in his opening address to the conference, treated the subject under two heads—namely, as affecting agricultural districts and in its relation to congested population. He further raised the question whether local authorities should have the power given to them of making or aiding in the making of cheap railroads. The committee, under the guidance of their chairman, Sir B. Samuelson, practically limited the enquiry to the case of light railways in agricultural districts, confining their consideration in this connection rather to the most likely method of cheapening parliamentary procedure and construction of lines than to the financial problem involved. As a result, a report was in February last presented to a further meeting of the conference and agreed to. This report expressed an opinion favourable to the authorisation and control of light railways being conferred on the local authorities, reserving an ultimate appellate jurisdiction to the Board of Trade, the belief being expressed that if this were done the initial cost of construction and expenses of working would be so reduced as to enable many light railways and tramways to be undertaken. The report concluded with an intimation that the committee refrained from giving an opinion as to the desirableness of local authorities being empowered to contribute towards or take part in undertakings of this character, doubting whether this was within the terms of the reference. Several memoranda were appended to the report by members, mostly dealing with the financial part of the question omitted from the report The Bill brought in by Mr. Bryce and Mr. Secretary Asquith, and now awaiting second reading, purports to give effect to the above report. The preamble of the Bill states its purport—viz, to provide by light railways further facilities for communication, especially in agricultural districts, and for that purpose to modify existing requirements. Briefly, the scheme of the Bill is to enable county councils to authorise the construction of light railways within their counties by means of an order made after public enquiry held by the county council. The order is to be submitted to the Board of Trade, which is to be charged with the duty of deciding whether the matter should go to Parliament, and as to the requirements for public safety and compulsory acquisition—subject, however, to agreement between the county council, the promoters, and the Board of Trade—an order is to have full effect. The provisions of the Lands Clauses Act are not to apply unless so provided by the order, and in any case all purchase and compensation money is to be settled by a single arbitrator appointed by the Board of Trade. The Bill also provides for the appointment, when required by reason of a light railway passing through several counties, of a joint committee, but it does not define the term "light railway," and it would seem (especially from the preamble referred to) that tramways are not contemplated in the term. The Bill does not, of course, exclude the Council from its operation, but it is evidently not framed with a view to embrace in its purview London and its suburbs. The Bill is silent on the financial part of the question, and is in short little, if anything, more than an attempt to revive in a modified form the Railways Construction Facilities Act of 1864, which enabled the Board of Trade to authorise a railway by means of a certificate, an Act which is said to have remained a dead letter owing to the fact that the consent of all persons beneficially interested is made a condition precedent to any certificate. The present Bill proposes to get over this part of the difficulty by constituting the Board of Trade the judge as to whether the views of dissenting parties are to prevail or not, thus shifting the responsibility from Parliament to a department of the State. It is possible that the Bill may in some cases be helpful and may encourage light railway enterprise in districts where landowners and others favour them, but for London and large urban districts it holds out no hope of assistance, and considering the twofold object of the conference, as indicated in Mr. Bryce's address referred to, it is disappointing to find that the Bill which is its product deals with but one of these objects, and that one in but a partial and hesitating manner. If the question of light railways is to be grappled with in connection with the needs of urban population it can only, we think, be by treating the term as synonymous with tramways and tramroads. We have, pursuant to a resolution of the Council of October 3, 1893, been engaged, through the statistical department, in collecting statistics relating to the whole question of locomotion as it

Digitized by Google

affects London, and are about presenting to the Council a plan and return indicating all the existing railway, tramway, and omnibus routes. This plan will serve to show how far the tramway service of London is from a stage of fair development, extension into outer London, and consequent connection with the agricultural and producing districts. It appears to us that a measure such as the Light Railways Bill ought not to be allowed to become law without some strong representations being made of the views of the Council as to the urgent necessity for full enquiry into those branches of the problem left undisposed of, both by the recent conference and by the present Bill The following quotation from Mr. Bryce's address puts very clearly the question as it touches London. "There is," he said, "the question whether the local authority should have the power to make cheap railroads or aid in the making of cheap railroads, and, if it shall have power, whether that power should be given it in the form of enabling it to own and work the line, or only to make the line, and then to lease the line or to guarantee a minimum dividend upon the line; and whether there shall be any power reserved for the ultimate acquisition upon certain terms of the railroad by the local authority." These questions Mr. Bryce described as "very difficult ones," but they have been solved or are in course of solution in other countries, and unless they are faced here not only must the natural expansion of our cities be retarded, but no efforts will be found effectual to control overcrowding. We recommend that a communication be made to her Majesty's Government, expressing the hope that if the Light Railways Bill is proceeded with and referred to a select committee there may be added to that committee's reference a special instruction to make full enquiry into the questions above referred to, and that the Home Secretary and Mr. Bryce be asked to receive a deputation on the subject.

PROVISIONAL PATENTS, 1895.

JUNE 17.

11708. **Improvements in electrically and directly controlled switches for electricity.** Robert Pippette, 51, Upper Tulse-hill, London.

11728. **Improvements connected with galvanic batteries and switches therefor.** William Shaw, 70, Wellington street, Glasgow. (Complete specification.)

11748. **Improvements in the application of telephones to electric bell systems.** Frederick Hodgson and George Alfred Edwards, 8, Agincourt-road, Hampstead, London.

11752. **Electro-deposition of gold and silver.** Emile Andreoli, 18, Somerleyton-road, London. (Complete specification.)

11758. **Instantaneous automatic electric lighter for all kinds of gas burners.** Cesare Della Torrie and Francesco Mancini, 52, Chancery-lane, London.

11770. **Improvements in or relating to telegraphic transmitters and recording apparatus therefor.** Alfred Julius Boult, 323, High Holborn, London. (Charles Spiro, United States.)

JUNE 18.

11801. **Improvements in and relating to reflectors for electric incandescent lamps.** Charles Darrah, 70, Market-street, Manchester.

11817. **Improvements in apparatus for measuring or indicating the frequency of alternating or pulsating electric currents or potential differences or other periodic disturbances.** Albert Campbell, 34, St. George's square, Regent's Park, London.

11832. **Improvements in or relating to secondary batteries.** Alfred Julius Boult, 323, High Holborn, London. (Nathan Huntly Edgerton, United States.)

11842. **Improvements in rheostats and other circuit controllers.** Philip Arthur Newton, 6, Bream's-buildings, Chancery-lane, London. (Charles Willms, United States.) (Complete specification.)

11864. **An improved plate for electric accumulators or storage batteries.** Paul Ribbe, 6, Lord-street, Liverpool. (Complete specification.)

JUNE 19.

11892. **A hand-feed lamp or regulator for the electric arc light for projection purposes.** Cecil Milton Hepworth, 45, St. Augustine's-road, Camden-square, London.

11944. **Improvements in the electrolytic deposition of metals and in means applicable therefor.** Charles Raleigh, 191, Fleet-street, London.

11951. **Improved system of telephonic exchange** Salomon Berditschewsky, called Apostoloff, 53, Chancery-lane, London.

JUNE 20.

11973. **Improvements in lights and reflectors for photography by electric and other lamps.** Charles Brooke Crawshaw and Rankin Kennedy, Hubert-street, Leeds-road, Bradford.

11976. **Improvements in electric safety lamps for use in mines and other places.** Henry William Headland, 77, Chancery-lane, London.

12035. **Mechanism for cutting off gas or electric current at any desired time.** Thomas Joseph Phipps, 24, Southampton-buildings, Chancery-lane, London.

11982. **Improvements in electromagnetic devices for automatically breaking the connections with the source of supply of electric light and power cables.** Sydney Ferris Walker, Cardiff Electrical Works, Severn-road, Cardiff.

12030. **Improvements in electric arc lamps.** William James Davy, 40, Chancery-lane, London.

12042. **Improvements in globes for arc lights or other lights of great intensity.** William Jandus, 18, Southampton-buildings, Chancery-lane, London.

JUNE 22.

12157. **Improvements in electric lighting, specially applicable for lighting vehicles.** Francis Louis Berners and Frederick Griffin, 40, Chancery-lane, London.

12161. **Improvements in apparatus for automatically indicating the fracture of electric conductors.** Adrien J. Moulart, 1, Queen Victoria street, London. (Complete specification.)

SPECIFICATIONS PUBLISHED.

1892.

19714. **Dynamo-electric machines.** Chitty. (Second edition.)

1893.

21628. **Telegraphy.** Delany. (Second edition.)

1894.

10463 **Electric batteries.** Moffat.

13700. **Telephone switchboard mechanism.** Kingsbury. (Western Electric Company.)

13499. **Electrolytical decomposition of alkali salts.** Sinding-Larsen. (Second edition.)

1895.

3178. **Testing boxes, etc., for electric mains.** Macpherson.

4497. **Electromagnetic apparatus for operating indicators, etc.** Von Morstein.

5700. **Electric arc lamps.** MacIntire.

6249. **Aerial electric railway systems.** Boult. (Kilmore.)

7142 **Alternating currents.** Manchester Edison-Swan Company and others.

7795. **Electric accumulators.** De Dormael.

8590. **Magnetic ore separators.** Carter.
